- Colo-anorectal disorders (cancer, masses, stenosis, strictures)
- Neurologic (stroke, dementia, Parkinson's, autonomic neuropathy)
- Psychiatric (depression, anxiety)

**Drugs Associated with Constipation include:**
- OTC (antihistamines, NSAIDs)
- Opioids
- Psychotropic (antipsychotics, TCAs)
- Anticholinergics
- Calcium channel blockers
- Diuretics
- Supplements (iron or calcium)

Diagnostic approach to chronic constipation in adults. Am Fam Physician 2011;84:299-306

**Treatment of Constipation in Older Adults**
Can Med Assoc J 2013;185(8):663-70
**Objectives**: To discuss management of constipation in older adults.
**Results/Conclusions**: In older adults, the predominant symptom of constipation is more frequently straining than decreased stool frequency. RCTs support the use of osmotic agents to treat symptoms of constipation in older adults. In contrast, evidence supporting the use of bulk agents, stool softeners stimulants, and prokinetic agents is lacking, limited, and inconsistent.

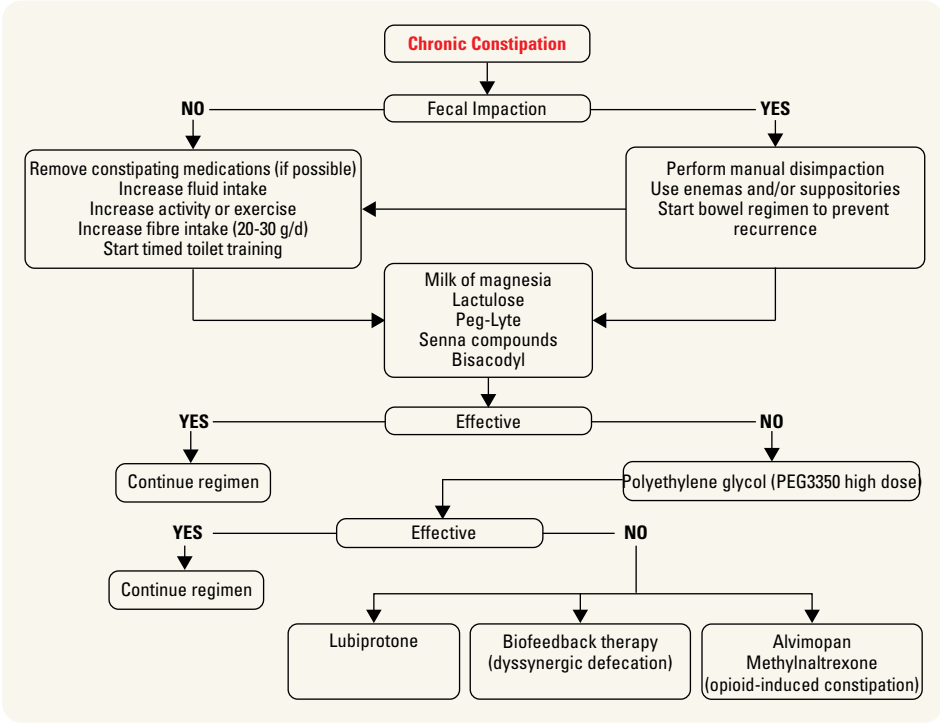

**Figure 2. Treatment algorithm for the management of chronic constipation in the elderly**
Adapted from: Clin Interv Aging 2010;5:163-171

# Incontinence

## FECAL INCONTINENCE

### Definition
- involuntary or inappropriate passing of feces that impacts social functioning or hygiene
- severity can range from unintentional flatus to the complete evacuation of bowel contents
- there are three subtypes:
  1. passive incontinence: involuntary discharge of stool or gas without awareness
  2. urge incontinence: discharge of fecal matter in spite of active attempts to retain bowel contents
  3. fecal seepage: leakage of stool following otherwise normal evacuation

**Transient Causes of Incontinence**

**DIAPERS**
**D**elirium
**I**nfection
**A**trophic urethritis/vaginitis
**P**harmaceuticals
**E**xcessive urine output
**R**estricted mobility
**S**tool impaction

### Epidemiology
- the incidence of fecal incontinence differs by setting: community (17-36%), hospital (16%) and nursing home (33-65%)
- risk factors: constipation, age >80 yr, female sex, urinary incontinence, impaired mobility, dementia, neurologic disease

### Etiology
- physiological changes with age >80 yr (e.g. decreased external sphincter strength, decreased resting tone of internal sphincter, weakened anal squeeze, increased rectal compliance, and impaired anal sensation)
- trauma (e.g. vaginal delivery, pudendal nerve damage, cauda equina)
- iatrogenic
  - surgical (e.g. anorectal surgery, lateral internal sphincterotomy, hemorrhoidectomy, colorectal resection)
  - radiation (e.g. pelvic radiation)
- neurogenic (e.g. neuropathy, stroke, MS, diabetic neuropathy)
- anorectal/colorectal diseases (e.g. rectal prolapse, hemorrhoids, IBD, rectocele, cancer)
- medication (e.g. laxative, anticholinergics, antidepressants, caffeine, muscle relaxants)
- cognitive (e.g. dementia, willful soiling with psychosis)
- constipation/fecal impaction

### Investigations (if cause not apparent from history and physical)
- differentiate true incontinence from frequency and urgency (e.g. IBS, IBD)
- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

### Management
- physiological changes with age: medication management (anti-motility agents (e.g. loperamide), diet/bulking agents for loose stool) increase fluid intake, biofeedback, retraining of pelvic floor muscles, surgery
- trauma: direct surgical repair or augmentation of the sphincters
- iatrogenic: surgical repair, artificial sphincters
- neurogenic: medication management, abdominal massage, digital stimulation for dysfunction, biofeedback and behavioural training, prevent autonomic dysreflexia in spinal injury
- anorectal/colorectal diseases: treat underlying cause (optimize IBD medications), surgical (e.g. mass removal, prolapse repair, hemorrhoid removal, colostomy)
- medication-related causes: stop laxatives, lower dose or discontinue any other offending agents
- cognitive: regular defecation program in patients with dementia, psychiatric consult (optimize medications and cognitive function)
- constipation/fecal impaction: disimpaction, prevent impaction, enema or rectal irrigation

## URINARY INCONTINENCE
- see Urology, U6

### Definition
- complaint of any involuntary loss of urine
- there are 4 subtypes:
  1. stress incontinence: leakage associated with physical strain
  2. urge incontinence: leakage associated with strong urge to urinate
  3. overflow incontinence: leakage associated with poor bladder emptying
  4. functional incontinence: leakage due to illness or disability not related to the urinary tract

### Epidemiology
- 15-30% prevalence dwelling in community and at least 50% of institutionalized seniors
- morbidity: cellulitis, pressure ulcers, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality
- risk factors: impaired mobility, falls, medications, depression, TIA/stroke, dementia, CHF, obesity

### Etiology
- physiologic changes with age: decreased bladder capacity
- genitourinary diseases (e.g. cystitis, urethritis, benign prostatic hyperplasia)
- neurogenic (e.g. cauda equina syndrome, stroke, MS)
- iatrogenic: prostate surgery
- trauma: pelvic trauma, traumatic spinal cord injury
- drugs (e.g. alcohol, loop diuretics, sedative hypnotics, GABAergic agents)
- cognitive (e.g. dementia, depression)
- functional impairment (e.g. arthritis, poor vision)

### Investigations
- urinalysis and culture

### Management
- lifestyle modification: avoid excessive fluid intake and alcohol
- pharmacologic: **β**-adrenergic agonists to reduce involuntary bladder contractions
- physiologic changes with age: pelvic muscle exercises, bladder training, biofeedback
- genitourinary diseases: treat underlying cause (empiric antimicrobial treatment for cystitis, **α** blockers/5-**α** reductase inhibitors for benign prostatic hyperplasia)
- functional impairment: incontinence pads, environmental modification, personal assistance
- cognitive: referral to incontinence program if needed

# Immobility

### Complications
- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- musculoskeletal: atrophy, contractures, bone loss
- skin: pressure ulcers
- psychological: sensory deprivation, delirium, depression

# Pressure Ulcers

• see Plastic Surgery, PL17

## Definition

• any lesion caused by unrelieved pressure resulting in damage of underlying tissue; usually develops over bony prominences

## Risk Factors

• extrinsic: friction, pressure, shear force
• intrinsic: immobility, malnutrition, moisture, sensory loss
• geriatric: age related skin changes, bed-bound, cognitive impairment, chronic illness, use of anti-hypertensive medications

**Table 4. Classification of Pressure Ulcers**

| | |
|---|---|
| **Stage I** | Changes include skin temperature, tissue consistency or sensation |
| | An area of persistent erythema in lightly pigmented, intact skin; in darker skin, it may appear red, blue or purple |
| **Stage II** | Partial thickness skin loss involving the epidermis, dermis or both |
| | The ulcer is superficial and presents as an abrasion, blister or shallow crater |
| **Stage III** | Full thickness skin loss involving damage or necrosis of subcutaneous tissue which may extend down to, but not through, underlying fascia |
| | Presents as a deep crater with or without undermining of adjacent tissue |
| **Stage IV** | Full thickness skin loss with extensive destruction, tissue necrosis or damage to muscle, bone or supporting structures |
| | May have associated undermining and/or sinus tracts |

## Prevention

• pressure reduction
  ▪ frequent repositioning
  ▪ pressure-reducing devices (static, dynamic)
• maintaining nutrition, encouraging mobility and managing incontinence
• use validated pressure injury risk assessment tools on admission for those identified to be at risk for skin breakdown (Canadian Association of Wound Care, 2018)

## Treatment

• optimize nutritional status
• minimize pressure on wound
• analgesia
• all ulcers with necrosis warrant debridement (mechanical, enzymatic and autolytic are non-urgent forms of debridement, whereas sharp debridement is performed urgently due to risk for sepsis or cellulitis)
• dressing application (exudate absorbing, barrier products to reduce friction)
• maintain moist wound environment to enable re-epithelialization
• treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
• diabetic foot ulcers: offloading with removable cast walker (e.g. aircast boot), orthopedic shoes and orthotics
• swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
• referral to Wound Care
• consider other treatment options
  ▪ negative pressure wound therapy/vacuum-assisted closure
  ▪ biological agents: application of fibroblast growth factor, platelet-derived growth factor to wound
  ▪ non-contact normothermic wound therapy
  ▪ electrotherapy

**Risk Assessment and Prevention of Pressure Ulcers**
Ann Intern Med 2015;162:359-369
The American College of Physicians (ACP) strongly recommends advanced static mattresses or advanced static overlays for patients who are at an increased risk of developing pressure ulcers. The ACP also recommends against using alternating air-mattresses or alternating-air overlays.

# Hazards of Hospitalization

**Table 5. Recommendations for Sequelae of Hospitalization in Older Patients**

| Sequelae | Recommendations |
|---|---|
| **Malnutrition** | No dietary restrictions (except diabetes), assistance, dentures if necessary, sitting in a chair to eat |
| **Urinary Incontinence** | Medication review, remove environmental barriers, discontinue use of catheter |
| **Depression** | Routine screening |
| **Adverse Drug Event** | Medication review |
| **Confusion/Delirium** | Orientation, visual and hearing aids, volume repletion, noise reduction, early mobilization, medication review, remove restraints |
| **Pressure Ulcers** | Low-resistance mattress, daily inspection, repositioning every 2 h |
| **Infection** | Early mobilization, remove unnecessary IV lines, catheters, NG tubes |
| **Falls** | Appropriate footwear, assistive devices, early mobilization, remove restraints, medication review |
| **Hypotension/Dehydration** | Early recognition and repletion (ideally oral rehydration, if possible) |
| **Diminished Aerobic Capacity/ Loss of Muscle Strength/ Contractures** | Early mobilization |
| **Decreased Respiratory Function** | Incentive spirometry, physiotherapy |
| **Functional Decline** | Structured exercise, progressive resistance training, walking programs |

Source: Asher, Richard AJ. Dangers of going to bed. British Medical Journal 2.4536 (1947): 967

# Elder Abuse

## Definition

- includes physical abuse, sexual abuse, emotional/psychological abuse, financial exploitation and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada and in most U.S. states

## Epidemiology

- in Canada in 2013, almost 3000 seniors were victims of family violence. The perpetrators of family violence against seniors were identified to be their grown child (43% of cases) and their spouses (28% of the cases)
- in older adults aged ≥60 yr, elder abuse is estimated to occur in 10% of patients
- insufficient evidence to include/exclude screening in the Periodic Health Exam

## Risk Factors

**Table 6. Risk Factors for Elder Abuse**

| | |
|---|---|
| **Situational Factors** | Social |
| **Victim Characteristics** | Physical or emotional dependence on caregiver<br>Lack of close family ties<br>History of family violence<br>Dementia or recent deterioration in health |
| **Perpetrator Characteristics** | Related to victim<br>Dependency on older adult (e.g. financial dependency) |

# Presbycusis

- see Otolaryngology, OT19

# Driving Competency

## Reporting Requirements

- physician-reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia, and Alberta, where it is discretionary
- British Columbia, Ontario: must refer for re-test at ≥80 yr
- not an issue unique to geriatrics – any patient may suffer from a medical condition that impairs their ability to drive and should be reported
- in the U.S., varies by state

## Conditions that may Impair Driving

**Table 7. Conditions that Impair Driving**

| | |
|---|---|
| **Alcohol** | Patients with history of impaired driving and those with a high probability of future impaired driving should not drive until further assessed |
| | Alcohol dependence or abuse: if suspected, should be advised not to drive |
| | Alcohol withdrawal seizure: must complete a rehabilitation program and remain abstinent and seizure-free for 6 mo before driving |
| **Blood Pressure Abnormalities** | Hypertension: sustained BP >170/110 should be evaluated carefully |
| | Hypotension: sustained BP <90/60; if syncopal, discontinue driving until syncope is treated and preventable |
| **Cardiovascular Disease** | Suspected asymptomatic CAD or stable angina: no restrictions |
| | STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for 1 mo following hospital discharge |
| | NSTEMI with minor LV damage, unstable angina: no driving for 48 h if PCI or 7 d if no PCI performed |
| **Cerebrovascular Conditions** | TIA: should not be allowed to drive until a medical assessment is completed |
| | Stroke: should not drive for at least 1 mo; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure |
| **COPD** | Mild/moderate impairment: no restrictions |
| | Moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen |
| **Cognitive Impairment/ Dementia** | Moderate to severe dementia is a contraindication to driving; defined as the "inability to independently perform 2 or more IADLs or any basic ADL" |
| | Patients with mild dementia should be assessed; if indicated, refer to specialized driving testing centre; if deemed fit to drive, re-evaluate patient every 6-12 mo |
| | Poor performance on MMSE, clock drawing or Trails B suggests a need to investigate driving ability further |
| | MMSE score alone (whether normal or low) is insufficient to determine fitness to drive |
| **Diabetes** | Diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular or cerebrovascular disease) |
| | Insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 mo |
| **Drugs** | Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants |
| | Degree of impairment varies: patients should be warned of the medication/withdrawal effect on driving |
| **Hearing Loss** | Effect of impaired hearing on ability to drive safely is controversial |
| | Acute labyrinthitis, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves |
| **Musculoskeletal Disorders** | Physician's role is to report etiology, prognosis and extent of disability (pain, range of motion, coordination, muscle strength) |
| **Post-Operative** | Outpatient, conscious sedation: no driving for 24 h |
| | Outpatient, general anesthesia: no driving for ≥24 h |
| **Seizures** | First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head |
| | Epilepsy: can drive if seizure-free on medication and physician has insight into patient compliance |
| **Sleep Disorders** | If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive |
| **Visual Impairment** | Visual acuity: contraindicated to drive if <20/50 with both eyes examined simultaneously |
| | Visual field: contraindicated to drive if <120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously |

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

**Key Factors to Consider in Older Drivers**
**SAFEDRIVE**
**S**afety record
**A**ttention (e.g. concentration lapses, episodes of disorientation)
**F**amily observations
**E**thanol abuse
**D**rugs
**R**eaction time
**I**ntellectual impairment
**V**ision/**V**isuospatial function
**E**xecutive functions (e.g. planning, decision-making, self-monitoring behaviours)
Geriatrics 1996;51:36-45

**Cognitive Tests and Determining Fitness to Drive in Dementia: A Systematic Review**
J Am Geriatr Soc 2016;64(9):1904-17
**Objectives**: To examine the relationship between cognitive tests and driving to determine whether a cognitive assessment can be implemented as a tool to examine driver safety.
**Methods**: Systematic review of 28 studies investigating the relationship between cognitive functioning and driving in individuals with dementia.
**Results**: Composite batteries comprising multiple individual tests from different cognitive domains consistency predicted driving performance for individuals with dementia. Scores on individual tests or tests of a single cognitive domain did not predict driver safety.
**Conclusions**: While studies consistently found composite batteries predicted driving performance, these tests were not clinically usable as they lacked the ability to discriminate between safe and unsafe drivers. Need development of a reliable, valid composite battery that can correctly determine driver safety in patients with dementia.

# Health Care Institutions

**Table 8. Classification of Health Care Services and Institutions**

| Institution/Service | Description |
|---|---|
| **Community Support Services** | Health care services offered at home for those who can live independently at home or under the care of family members including professional health care services, personal care and support (ADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks, etc.) |
| **Rehabilitation** | Health care services offered in an institution to optimize patients' function, independence and quality of life |
| **Residential** | Divided into short (<60-90 d/yr) and long (indefinite) stay |
| **a) Seniors Affordable Housing** | Seniors who live independently and manage their own care, but prefer to live near other seniors; usually has accessibility features; rent is adjusted based on income |
| **b) Retirement Home** | Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned |
| **c) Supportive Housing** | Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment; may offer physiotherapy and rehabilitation services |
| **d) Long-term Care/Skilled Nursing Facility** | Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy, and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital |
| **e) Hospice** | Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤3 mo |

- names of community health care institutions, types of facilities, and services offered vary between geographical locations
- factors to consider when seeking services/institutions: level of care required, support networks, duration of stay, cost

# Geriatric Pharmacology

## Pharmacokinetics

**Table 9. Age-Associated Pharmacokinetics**

| Parameter | Age Effect | Implications |
|---|---|---|
| **Absorption** (less significant) | Increased gastric pH<br>Decreased splanchnic blood flow, GI absorptive surface and dermal vascularity; delayed gastric emptying | Drug-drug and drug-food interactions are more likely to affect absorption |
| **Distribution** | Increased total body fat<br>Increased α1-glycoprotein<br>Decreased lean body mass and total body water<br>Decreased albumin | Lipophilic drugs have a larger volume of distribution<br>Increased binding of basic drugs<br>Decreased volume of distribution of hydrophilic drugs<br>Decreased binding of acidic drugs |
| **Metabolism** (less significant) | Decreased hepatic mass and hepatic blood flow; impaired phase I reactions (oxidative system) | Lower doses may be therapeutic |
| **Elimination** | Decreased renal blood flow, glomerular filtration rate, tubular secretion<br>Overall reduction in renal function by 30-50% | Lower doses may be therapeutic |

## Pharmacodynamics

### Drug Sensitivity
- changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives, antipsychotics, anticholinergics, digoxin, and narcotics
- decreased sensitivity to β-blockers and β-adrenergic stimulants, though may have increased sensitivity

### Decreased Homeostasis
- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

New medications: Start Low, Go Slow! Avoid starting 2 drugs at the same time

Adverse drug reactions in the elderly may present as delirium, falls, fractures, urinary incontinence/retention or fecal incontinence/impaction

# Polypharmacy

### Definition
- prescription, administration or use of more medications than are clinically indicated

### Epidemiology
- in Canada, >60% of elderly individuals reported using ≥5 medications
- hospitalized elderly are given an average of 10 medications during admission

### Risk Factors for Non-Compliance
- greater number of medications (compliance with 1 medication is 80%, but drops to 25% with ≥6 medications)
- increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

### Adverse Drug Reactions (ADRs)
- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in the elderly
  - intrinsic: comorbidities (>5), age >85, low BMI, age-related changes in pharmacokinetics and pharmacodynamics, CrCl <50 mL/min
  - extrinsic: number of medications, (>9 medications, >12 doses/d), multiple prescribers, unreliable drug history, prior ADR
- prescribing cascade: process whereby an ADR is misinterpreted as a new medical condition, and a subsequent drug is prescribed to treat the initial drug-induced event. Providers should ask themselves:
  - is the new drug being prescribed to address an adverse event from a previously prescribed drug therapy?
  - is the initial drug therapy potentially leading to a prescribing cascade really needed?
  - what are the harms and benefits of continuing the initial drug therapy?

### Preventing Polypharmacy
- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical comorbidities
- consider patient-drug interaction risk factors for ADRs
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an ADR with another medication

# Inappropriate Prescribing in the Elderly

### Epidemiology
- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

### Beers Criteria
- a list of medications to avoid in adults ≥65 yr due to safety concerns
- 2015 update lists drugs that should be avoided or dose-adjusted based on kidney function, as well as drug-drug interactions associated with harms in older adults
- examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives
- the elderly are often under-treated (ACEI, ASA, β-blockers, thrombolytics, oral anticoagulants)

### STOPP/START Criteria
- another screening tool for potentially inappropriate prescribing in the elderly
  - STOPP: Screening Tool of Older Person's Prescriptions
    - systems-based list of medications contraindicated in adults ≥65 in the context of their diagnoses
  - START: Screening Tool to Alert doctors to Right Treatment
    - systems-based list of medications indicated in adults ≥65 in the context of their diagnoses

**Principles for Prescribing in the Elderly**

**CARED**
**C**aution/Compliance
**A**ge (adjust dosage for age)
**R**eview regimen regularly
**E**ducate
**D**iscontinue unnecessary medications
Geriatric Pearls. Philadelphia: FA Davis Company, 1999

# Common Medications

**Table 10. Common Medications**

| Drug Name | Brand Name | Dosing Schedule | Indications | Contraindications | Side Effects | Mechanism of Action |
|---|---|---|---|---|---|---|
| **Cognitive Enhancers** | | | | | | |
| **donepezil** | Aricept® | 5-10 mg PO daily | Moderate to severe dementia of Alzheimer's type | Known hypersensitivity, caution in untreated obstructive airways disease, cardiac conduction abnormalities, active PUD, seizure disorder, syncope NYD | N/V, diarrhea, anorexia, falls, hip fracture, increased need for pacemaker insertion | Reversible inhibition of acetylcholinesterase |
| **galantamine** | Reminyl® | 8-12 mg PO bid | Mild to moderate dementia of Alzheimer's type | Known hypersensitivity, caution in untreated obstructive airways disease, cardiac conduction abnormalities, active PUD, seizure disorder, syncope NYD | N/V, diarrhea, anorexia, falls, hip fracture, increased need for pacemaker insertion | Reversible inhibition of acetylcholinesterase |
| **rivastigmine** | Exelon® | 1.5 mg PO daily (starting) up to 6 mg PO bid | Mild to moderate dementia of Alzheimer's type | Known hypersensitivity, severe hepatic disease, caution in untreated obstructive airways disease, cardiac conduction abnormalities, active PUD, seizure disorder, syncope NYD | N/V, diarrhea, anorexia, falls, hip fracture, increased need for pacemaker insertion | Acetylcholinesterase inhibition (reversible but very slow) |
| **memantine** | Ebixa®/Namenda® (Can)/(U.S.) | 5 mg PO daily (starting) up to 10 mg PO bid | Mild to moderate dementia of Alzheimer's type | Known hypersensitivity, conditions that alkalinize urine, caution in renal failure, seizures | Agitation, fatigue, dizziness, headache, hypertension, constipation | NMDA-receptor antagonist |
| **Laxatives** | | | | | | |
| **bran** | All-Bran® | 1 cup OD | Constipation | | Bloating, flatus | Bulk-forming laxative |
| **psyllium** | Metamucil® Prodiem Plain® | 1 tsp PO tid | Constipation, hypercholesterolemia | N/V, abdominal pain, obstruction | Bloating, flatus | Bulk-forming laxative |
| **lactulose** | Chronulac® Cephulac® Kristalose®(U.S.) Acilac; Apo-Lactulose®; Laxilose; PMS-Lactulose (Can) | 15-30 cc PO OD/bid | Constipation, hepatic encephalopathy, bowel evacuation following barium exam | Patients on low galactose diets Abdominal pain, N/V | Flatus, cramps, nausea, diarrhea | Hyperosmolar agent, lowers pH of colon to decrease blood ammonia levels |
| **senna** | Senokot®/Ex-lax® Glysennid® | 1-2 tabs PO daily or 10-15 cc syrup PO daily | Constipation | Abdominal pain, N/V | Cramps, N/V , diarrhea | Stimulant laxative |
| **PEG 3350 (polyethylene glycol)** | Lax-A-Day®, RestoraLAX®, Pegalax® (Can) Gavilax®, Healthylax® (U.S.) | 17 g (~1 heaping tablespoon) dissolved in 120 to 240 mL (4 to 8 ounces) of beverage, OD | Constipation, bowel prep (different dosing schedule) | Known/suspected bowel obstruction, known hypersensitivity, renal impairment | Abdominal cramps, bloating of the stomach, diarrhea, flatulence, nausea | Osmotic laxative |
| **bisacodyl** | Dulcolax® | 5-15 mg PO (10 mg PR) | Constipation | Ileus, obstruction, abdominal pain, N/V, severe dehydration | Cramps, pain, diarrhea | Stimulant laxative |
| **Parkinsonian Agents** – see Neurology, N32 | | | | | | |

Note: Docusate has been shown to be ineffective for the prevention/treatment of constipation in the elderly

# Landmark Geriatric Trials

| Trial | Reference | Results |
|---|---|---|
| Delirium in Older Persons: Advances in Diagnosis and Treatment | JAMA 2017; 318(12):1161-1174 | Advances in diagnosis can improve recognition and risk stratification of delirium. Prevention of delirium using nonpharmacologic approaches is effective, while pharmacologic prevention and treatment of delirium remains controversial |
| Assessment and management of falls in older people | Can Med Assoc J 2014;186(16):E610-21 | Targeted history and physical examination, covering potential home hazards, cognitive and visual impairment, functional limitations, medications, orthostatic hypotension, and gait and balance abnormalities, can be used to identify risk factors for falls. Numerous interventions (single and multicomponent) can decrease the risk of falls. At a minimum, patients who have experienced a fall should be encouraged to participate in an approved exercise program to help prevent further falls |
| Dementia prevention, intervention, and care | Lancet 2017; 390(10113): 2673-2734 | Recommend active treatment of hypertension in middle aged (45–65 yr) and older people (aged older than 65 yr) without dementia to reduce dementia incidence. Interventions for other risk factors including more childhood education, exercise, maintaining social engagement, reducing smoking, and management of hearing loss, depression, diabetes, and obesity could delay or prevent a third of dementia cases |
| Optimal management of urinary tract infections in older people | Clin Interv Aging 2011;6:173-180 | UTIs are over diagnosed and over treated in older people. Asymptomatic bacteriuria is very common in later life and should not be screened for or treated |
| Delirium is a strong risk factor for dementia in the oldest-old: a population-based cohort study | Brain 2012;135(9): 2809-16 | First population study to show that delirium is a strong risk factor for dementia and cognitive decline in elderly patients |
| Donepezil and Memantine for Moderate-to-Severe Alzheimer's Disease | New Engl J Med 2012;366:893-903 | Continued treatment with donepezil was associated with cognitive benefits over the course of 12 mo in patients with moderate or severe Alzheimer's disease |
| Hip protectors for fracture prevention | New Engl J Med 2000;343:1506-1513 | The risk of hip fracture can be reduced in frail elderly adults by the use of an anatomically designed external hip protector |
| HYVET | New Engl J Med 2008;358:1887-1898 | Antihypertensive treatment with indapamide (sustained release), with or without perindopril, in adults 80 yr or older is beneficial |
| PROFET | Lancet 1999;353:93-97 | Demonstrates that an interdisciplinary approach to elderly adults with a previous history of falls can significantly decrease the risk of further falls and limit functional impairment |
| Reduction of inappropriate benzodiazepine prescriptions through patient education: the EMPOWER cluster randomized trial | JAMA Intern Med 2014;174:890-898 | Direct-to-consumer education describing the risks of benzodiazepine use and a stepwise tapering protocol effectively elicits shared decision making and discontinuation of medications that increase the risk of harm in older adults |
| Updated Beers Criteria for potentially inappropriate medication use in older adults | J Am Geriatr Soc 2015;63:2227-46 | A 13-member interdisciplinary panel of experts in geriatric care and pharmacotherapy updated the 2012 AGS Beers Criteria for medications to be avoided or dose-adjusted in older adults |
| STOPP and START. Consensus validation | Int J Clin Pharmacol Ther 2008;46:72-83 | STOPP/START is a valid, reliable, and comprehensive screening tool that enables the prescribing physician to appraise an older patient's prescription drugs in the context of his/her concurrent diagnoses |
| Frailty in older adults: evidence for a phenotype | J Gerontol A Biol Sci Med Sci 56:M146-56 | This study provides a potential standardized definition of frailty in community-dwelling older adults, where three or more of the following criteria are present: unintentional weight loss, exhaustion, weakness, slow walking speed, and low physical activity |
| Tube feeding in patients with advanced dementia: A review of the evidence | JAMA 1999;282:1365-1370 | There is no direct data to support tube feeding of demented patients with eating difficulties for any of the commonly cited indications. Survival has not been shown to be prolonged by tube feeding |
| Systolic Hypertension in the Elderly Program (SHEP): antihypertensive efficacy of chlorthalidone | Am J Cardiol 1985;56:913-20 | Chlorthalidone is effective for lowering blood pressure in elderly patients with systolic hypertension |
| Systolic Hypertension in Europe (Syst-Eur) trial | Lancet 1997;350:757-64 | Among elderly patients with isolated systolic hypertension, antihypertensive drug treatment starting with nitrendipine reduces the rate of cardiovascular complications. Treatment of 1000 patients for 5 years with this type of regimen may prevent 29 strokes or 53 major cardiovascular endpoints |

# Basic Anatomy Review

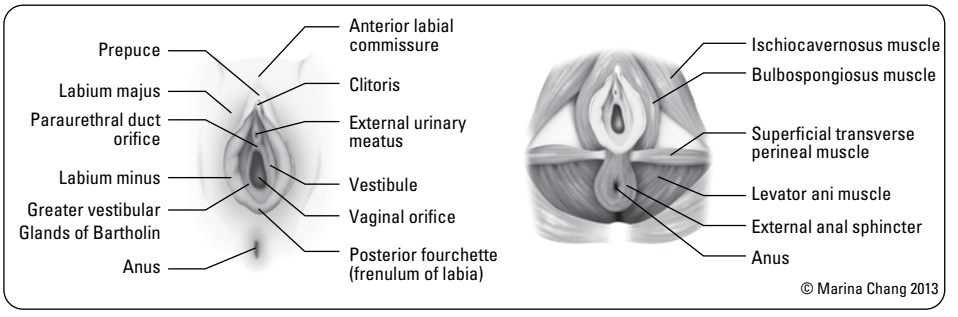

**Figure 1. Vulva and perineum**

## A. EXTERNAL GENITALIA

- blood supply: internal pudendal artery
- sensory innervation: pudendal nerve
- lymphatic drainage: inguinal nodes

## B. VAGINA

- muscular canal extending from cervix to vulva, anterior to rectum and posterior to bladder
- lined by rugated, stratified squamous epithelium
- upper vagina separated by cervix into anterior, posterior, and lateral fornices
- blood supply: vaginal branch of internal pudendal artery with anastamoses from uterine, inferior vesical, and middle rectal arteries

## C. UTERUS

- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
  - uterine corpus
    - blood supply: uterine artery (branch of the internal iliac artery, anterior division)
  - cervix
    - blood supply: cervical branch of uterine artery
- supported by the pelvic diaphragm, the pelvic organs, and 4 paired sets of ligaments
  - round ligaments: travel from anterior surface of uterus, through broad ligaments, and inguinal canals then terminate in the labia majora
    - function: anteversion
    - blood supply: Sampson's artery (branch of uterine artery running through round ligament)
  - uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
    - function: mechanical support for uterus, prevent prolapse and contain autonomic nerve fibres
  - cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
    - function: mechanical support, prevent prolapse
  - broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels, and lymphatics

- infundibulopelvic ligament (suspensory ligament of the ovary): continuous tissue that connects ovary to pelvic wall
  - contains the ovarian artery, ovarian vein, ovarian plexus, and lymphatic vessels
- position of the uterus
  - anteverted (majority), retroverted, neutral

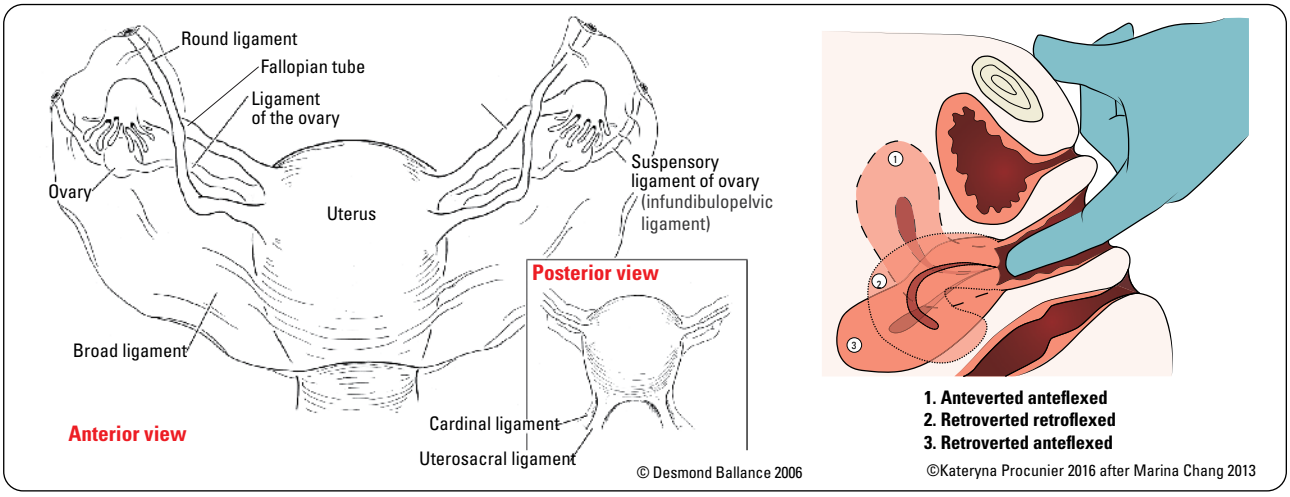

**Figure 2. Genital organs and positioning of the uterus**

## D. FALLOPIAN TUBES

- 8-14 cm muscular tubes extending laterally from the uterus to the ovary
- interstitial, isthmic, ampullary, and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

## E. OVARIES

- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off of aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

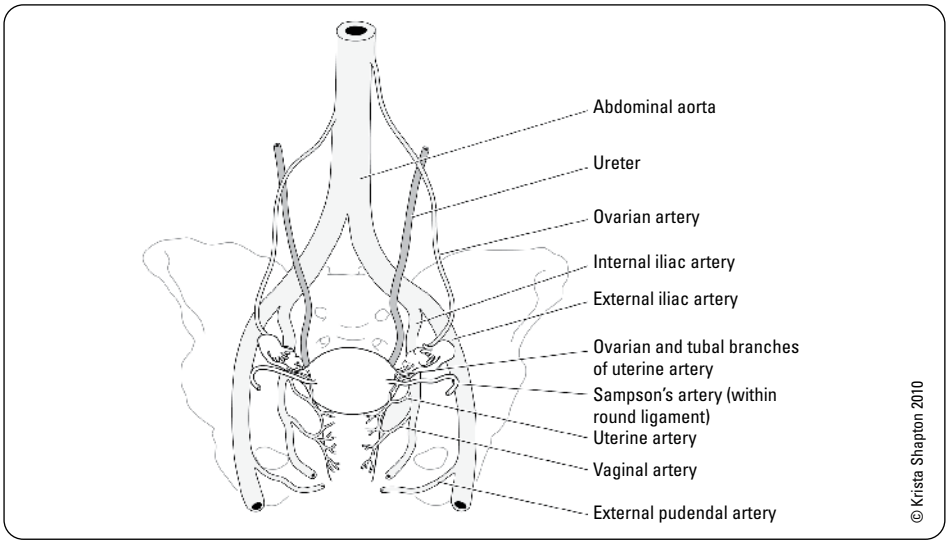

**Figure 3. Vascular supply**

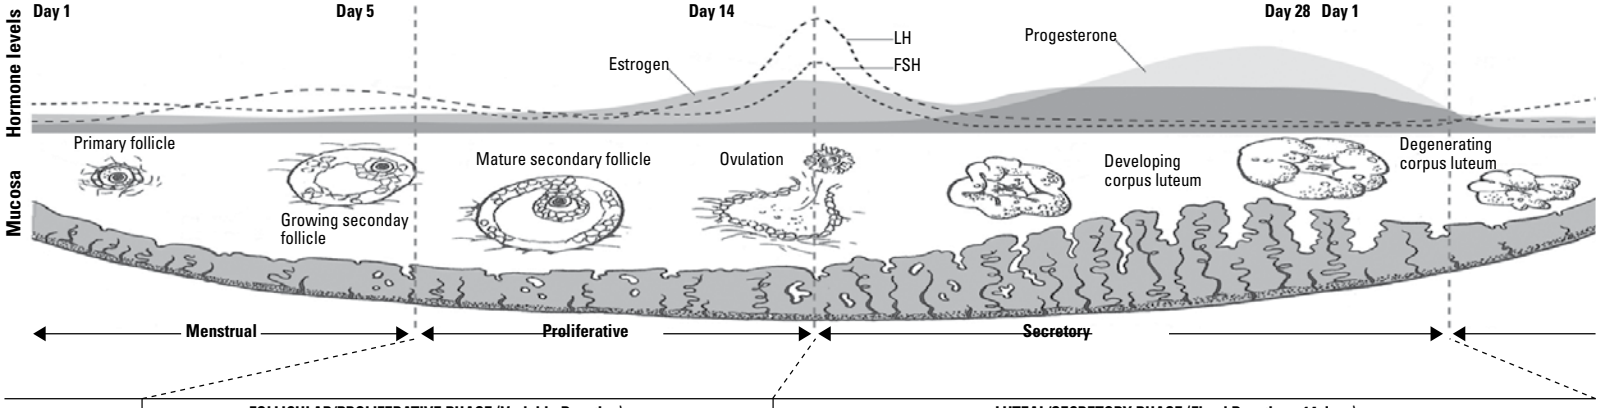
**Determination of Uterine Position by Clinical Exam**

- If cervix faces anteriorly (under the urethra and less easily accessible), i.e. toward vaginal orifice, more likely RETROVERTED UTERUS
- If cervix faces posteriorly (easily accessible), i.e. toward sacrum or rectum, more likely ANTEVERTED UTERUS
- If uterus palpable on bimanual exam, more likely ANTEVERTED UTERUS



**"Water Under the Bridge"**
The ureters run posterior to the uterine arteries

**Common Anatomy Questions in the OR**

- **What is the origin of the left and right ovarian arteries?**
  Descending aorta
- **What are the drainage sites for the left and right ovarian veins?**
  Left to left renal vein, right to inferior vena cava
- **What is the most common place to locate the ureter?**
  Pelvic brim, medial leaf of the broad ligament as it passes under the uterine artery
- **Which artery runs under the round ligament?**
  Sampson's artery

# Menstruation

## Menstrual Cycle

| | FOLLICULAR/PROLIFERATIVE PHASE (Variable Duration) | | | LUTEAL/SECRETORY PHASE (Fixed Duration - 14 days) | | |
|---|---|---|---|---|---|---|
| | **Early** | **Mid** | **Late** | **OVULATION** | **Early-Mid** | **Late** |
| **Initiating Events** | ↓ E and ↓ P (from end of previous cycle) | ↑ FSH acts on ovarian granulosa cells | Growing follicles continue to secrete E | Sudden switch from negative to positive feedback (E and P now ↑ FSH & LH) | Switch back to negative feedback | No fertilized oocyte |
| **HPO Axis** | ↑ GnRH pulse frequency<br>↑ FSH<br>↑ LH pulse frequency | ↑ E from follicles (ovary) | | ↑↑ LH pulse amplitude (LH surge) | ↓ LH | |
| **Hormones** | | | ↑ E from follicles, especially from dominant follicle | E peaks → LH surge → ovulation | ↑ P from corpus luteum | ↓ P secondary to degeneration of corpus luteum |
| **Feedback on HPO Axis** | | Negative feedback E → ↓ FSH, ↓ LH | | Positive feedback: E and P → ↑ FSH, ↑ LH | Negative feedback P → ↓ FSH, ↓ LH | |
| **Ovaries** | ↑ FSH → follicular growth in 3-30 follicles | ↑ follicular growth (by reducing atresia) → ↑ E | Dominant follicle persists, remainder undergo atresia<br>Granulosa cells luteinize → produce P | ~36 h after LH surge, dominant follicle releases oocyte; corpus luteum (remnant of dominant follicle) produces P | | Cessation of P from corpus luteum |
| **Endometrium** | Menses from P withdrawal (from end of previous cycle) | | E builds up endometrium | | P stabilizes endometrium | Withdrawal of P → menses |
| **Cervical Mucus** | | Cervical mucus: Clear, ↑ amount, Spinnbarkeit 8-10 cm, more stringy | | | | Cervical mucus: Opaque, scant amount, Spinnbarkeit 1-2 cm |

© Tess Peters 2009 and Sonya Amim 2003

E = estrogen; FSH = follicle-stimulating hormone; GnRH = gondatropin-releasing hormone; HPO = hypothalamic pituitary-ovarian; LH = lutenizing hormone; P = progesterone

**Figure 4. Events of the normal menstrual cycle**

**CHARACTERISTICS**
- Menarche 10-15 yr
- Average 12.2 yr
- Entire cycle 28 ± 7 d with bleeding for 1-6 d
- 25-80 mL blood loss per cycle

**ESTROGEN**
ESTROGEN is the main hormone in the follicular/proliferative phase and is stimulated by FSH. As the level increases it acts negatively on FSH. The majority of estrogen is secreted by the dominant follicle

Estrogen effects
- On the follicles in the ovaries
  - Reduces atresia
- On the endometrium
  - Proliferation of glandular and stromal tissue
- On all target tissues
  - Decreases E receptors

**PROGESTERONE**
PROGESTERONE is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone acts negatively on LH and is secreted by the corpus luteum (remnant of dominant follicle)

Progesterone effects
- On the endometrium
  - Cessation of mitoses (stops building endometrium up)
  - "Organization" of glands (initiates secretions from glands)
  - Inhibits macrophages, interleukin-8, and enzymes from degrading endometrium
- On all target tissues
  - Decrease E receptors (the "anti-estrogen" effect)
  - Decrease P receptors

# Stages of Puberty

- see Pediatrics, P31
- adrenarche: increased secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8 yr
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding

**Stages of Puberty**

**"Boobs, Pubes, Grow, Flow"**
Thelarche, Pubarche, Growth spurt, Menarche

**Tanner Stage**

**Thelarche**
1. None
2. Breast bud
3. Further enlargement of areolae and breasts with no separation of contours
4. 2º mound of areolae and papilla
5. Areolae recessed to general contour of breast – adult

**Pubarche**
1. None
2. Downy hair along labia only
3. Darker/coarse hair extends over pubis
4. Adult-type hair with no thigh involvement
5. Adult hair in distribution and type; extends over thighs. Not all patients achieve Tanner Stage 5. For image see Pediatrics, P32

# Premenstrual Syndrome

- synonyms: "ovarian cycle syndrome," "menstrual molimina" (moodiness)

## Etiology
- multifactorial: not completely understood; genetics likely play a role
- CNS-mediated neurotransmitter (serotonin, dopamine, GABA) interactions with sex steroids (P, E, and T)
- serotonergic dysregulation – currently most plausible theory

## Diagnostic Criteria for Premenstrual Syndrome
- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness or swelling, abdominal bloating, headache, swelling of extremities, joint or muscle pain, or weight gain
- symptoms relieved within 4 d of onset of menses and do not recur until at least day 13 of cycle
- symptoms present in the absence of any pharmacologic therapy, hormone ingestion, drug or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or occupational performance

**Premenstrual Syndrome**
Physiological and emotional disturbances that occur 1-2 wk prior to menses and last until a few days after onset of menses; common symptoms include depression, irritability, tearfulness, and mood swings

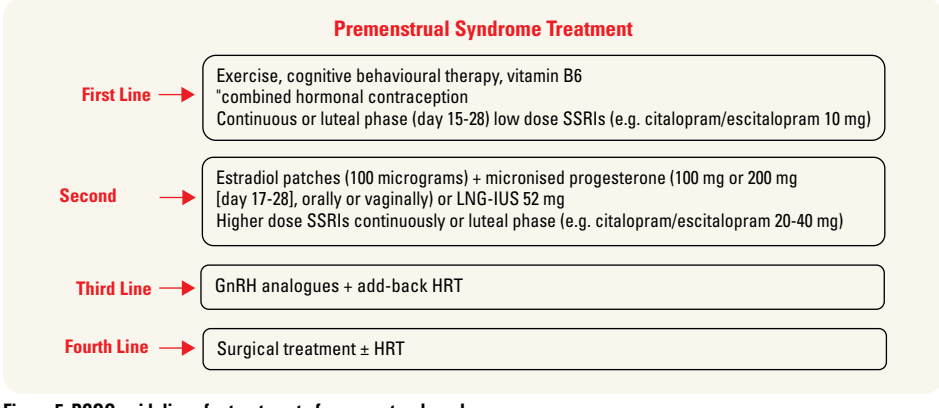


**Figure 5. RCOG guidelines for treatment of premenstrual syndrome**
Adapted from source: https://www.rcog.org.uk/globalassets/documents/guidelines/gt48managementpremensturalsyndrome.pdf

# Premenstrual Dysphoric Disorder

## Clinical Feature
- irritability, depressed mood
- breast pain and bloating

## Diagnostic Criteria for Premenstrual Dysphoric Disorder
- at least 5 of the following 11 symptoms during most menstrual cycles of the last year (with at least 1 of the first 4)
  - depressed mood or hopelessness
  - anxiety or tension
  - affective instability
  - anger or irritability
  - decreased interest in activities
  - difficulty concentrating
  - lethargy
  - change in appetite
  - hypersomnia or insomnia
  - feeling overwhelmed
  - physical symptoms: breast tenderness/swelling, headaches, joint/muscle pain, bloating, or weight gain
- symptoms cause significant distress and/or interfere with social or occupational functioning
- symptoms must be present during the week prior to menses and resolve within a few days after onset of menses
- may be superimposed on other psychiatric disorders, provided it is not merely an exacerbation of another disorder

# Common Investigations and Procedures

## Imaging

### Ultrasound (U/S)

- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if β-hCG ≥1500 (β-hCG must be ≥6500 for transabdominal U/S)
- may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, and ovarian masses (e.g. solid or cystic)
  - determine endometrial thickness, locate/characterize fibroids
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal women

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have β-hCG measured

## Endometrial Biopsy

- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
  - pre-treatment with misoprostol (Cytotec®) is optional
- more invasive procedure (i.e. D&C) may be done in the office or operating room ± hysteroscopy. This may be required if endometrial biopsy is not possible in the office setting or if there is suspicion for an endometrial polyp
- indications
  - AUB/PMB
    - age >40
    - risk factors for or history of endometrial cancer
    - failure of medical treatment
    - significant intermenstrual bleeding
    - consider in women with infrequent menses suggesting anovulatory cycles

## Hysterectomy

### Indications

- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

### Complications

- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)

### Approaches

1. Open (abdominal approach): uterus removed via transverse (Pfannenstiel) or midline laparotomy
2. Minimally invasive approaches
   - vaginal hysterectomy: entire procedure performed through the vagina. No abdominal incisions
   - laparoscopic-assisted vaginal hysterectomy: vascular pedicles are divided by a combination of laparoscopic and vaginal approaches
   - total laparoscopic hysterectomy: all vascular pedicles including the colpotomy approached laparoscopically and removed through the vagina
   - robotic: a type of laparoscopic approach. May be advantageous in high BMI patients. More costly

**No. 377 – Hysterectomy for Benign Gynaecological Indications**
J Obstet Gynaecol Can 2019;41(4):543-557
**Summary:**

1. Hysterectomy should be approached by either vaginal, laparoscopic, or open routes
2. Correction of preoperative anemia (hemoglobin <120 g/L), preoperative antibiotic prophylaxis, and measures to decrease risk of venous thromboembolism are recommended
3. In patients with endometriosis, full excision of local endometriosis should be performed concurrently
4. Opportunistic salpingectomy can be considered at the time of hysterectomy, but the planned surgical approach should not be changed for this sole purpose
5. Urinary tract injury is a known complication of hysterectomy and there should be a low threshold for further investigation in cases where injury is suspected- consider routine cystoscopy

Women should be counselled about the benefits and risks of removing the ovaries, the risk of ovarian cancer versus the long-term health implications of earlier menopause

**Table 1. Classification of Hysterectomy**

| Classification | Tissues Removed | Indications |
|---|---|---|
| **Subtotal Hysterectomy** | Uterus | Inaccessible cervix (e.g. adhesions)<br>Patient choice/preference<br>Severe endometriosis |
| **Total Hysterectomy (extrafascial simple hysterectomy/type 1)** | Uterus, cervix, uterine artery ligated at uterus | Uterine fibroids<br>Endometriosis<br>Adenomyosis<br>Heavy menstrual bleeding<br>DUB |
| **Total Hysterectomy (extrafasical simple hysterectomy/type 1) + Bilateral Salpingo-Oophorectomy** | Uterus, cervix, uterine artery ligated at uterus, fallopian tubes, ovaries | Endometrial cancer<br>Malignant adnexal masses<br>Consider for endometriosis |
| **Modified Radical Hysterectomy (type 2)** | Uterus, cervix, proximal 1/3 parametria, uterine artery ligated medial to the ureter, mid point of uterosacral ligaments, and upper 1-2 cm vagina | Cervical cancer (up to stage 1B1) |
| **Radical Hysterectomy (type 3)** | Uterus, cervix, entire parametria, uterine artery ligated at its origin from internal iliac artery, uterosacral ligament at most distal attachment (rectum), and upper 1/3-1/2 vagina | Cervical cancer |

# Disorders of Menstruation

## Amenorrhea

### Differential Diagnosis of Amenorrhea

**Table 2. Differential Diagnosis of Primary Amenorrhea**

| With Secondary Sexual Development | | Without Secondary Sexual Development | |
|---|---|---|---|
| **Normal breast and pelvic development** | **Normal breast, abnormal uterine development** | **High FSH (hypergonadotropic hypogonadism)** | **Low FSH (hypogonadotropic hypogonadism)** |
| Hypothyroidism<br>Hyperprolactinemia<br>PCOS<br>Hypothalamic dysfunction | Androgen insensitivity<br>Anatomic abnormalities<br>Müllerian agenesis, uterovaginal septum, imperforate hymen | Gonadal dysgenesis<br>Abnormal sex chromosome (Turner's XO)<br>Normal sex chromosome (46XX, 46XY) | Constitutional delay (rare in girls)<br>Congenital abnormalities<br>Isolated GnRH deficiency<br>Pituitary failure (Kallman syndrome, head injury, pituitary adenoma, etc.)<br>Acquired endocrine disorders (type 1 DM)<br>Pituitary tumours<br>Systemic disorders (IBD, JRA, chronic infections, etc.)<br>Functional hypothalamic amenorrhea |

**Most Common Causes of Primary Amenorrhea**
1. Müllerian agenesis
2. Abnormal sex chromosomes (Turner's syndrome)
3. Functional hypothalamic amenorrhea

**Table 3. Differential Diagnosis of Secondary Amenorrhea**

| With Hyperandrogenism | Without Hyperandrogenism |
|---|---|
| PCOS<br>Autonomous hyperandrogenism (androgen secretion independent of the HPO axis)<br>Ovarian: tumour, hyperthecosis<br>Adrenal androgen-secreting tumour<br>Late onset or mild congenital adrenal hyperplasia (rare) | Hypergonadotropic hypogonadism (i.e. primary ovarian insufficiency: high FSH, low estradiol)<br>Idiopathic<br>Autoimmune: type 1 DM, autoimmune thyroid disease, Addison's disease<br>Iatrogenic: cyclophosphamide drugs, radiation<br>Hyperprolactinemia<br>Endocrinopathies: most commonly hyper or hypothyroidism<br>Hypogonadotropic hypogonadism (low FSH):<br>Pituitary compression or destruction: pituitary adenoma, craniopharyngioma, lymphocytic hypophysitis, infiltration (sarcoidosis), head injury, Sheehan's syndrome<br>Functional hypothalamic amenorrhea (often related to stress excessive exercise and/or anorexia) |

Functional hypothalamic amenorrhea is the most common cause of secondary amenorrhea

## Investigations

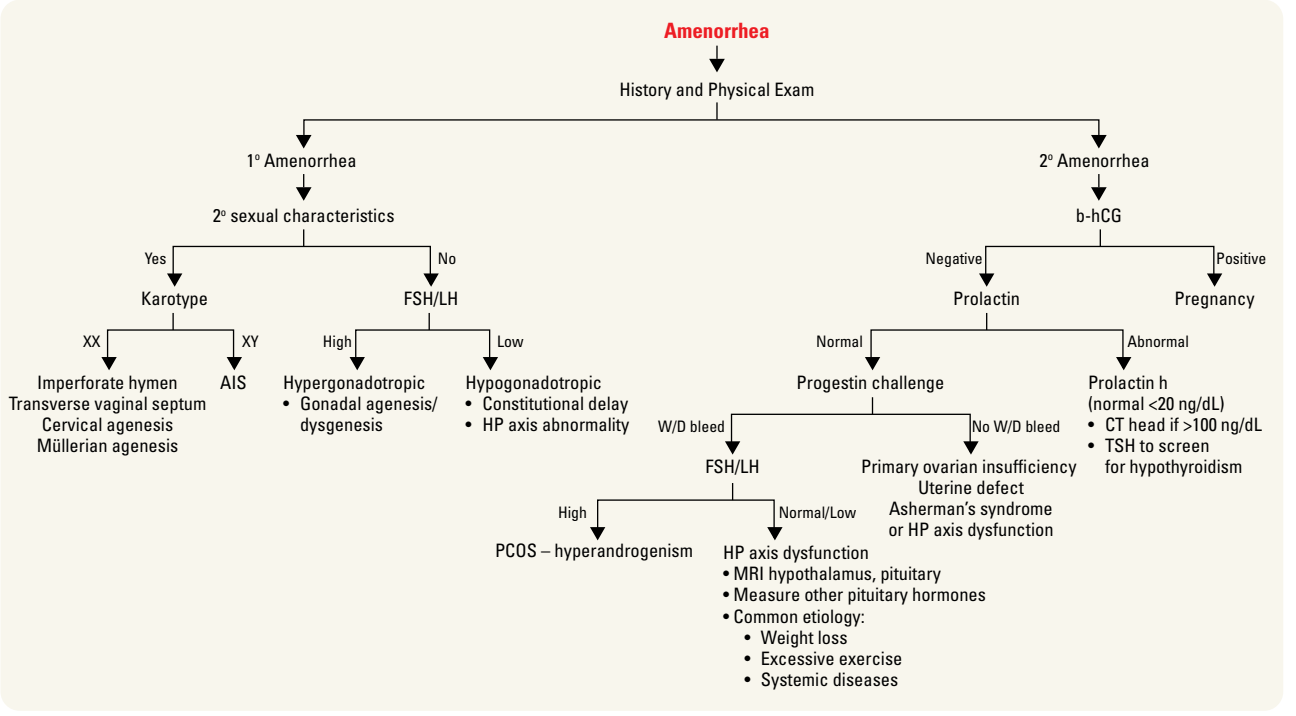

**Figure 6. Diagnostic approach to amenorrhea**

- β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
  - medroxyprogesterone acetate (Provera®) 10 mg PO OD for 10-14 d
  - any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive test/ withdrawal bleed
    - withdrawal bleed suggests presence of adequate estrogen to thicken the endometrium; thus withdrawal of progesterone results in bleeding
    - if no bleeding occurs, this may be secondary to inadequate estrogen (hypoestrogenism), excessive androgens, or progesterones (decidualization) or pregnancy
- karyotype: indicated if primary ovarian insufficiency or absent puberty
- U/S to confirm normal anatomy, identify PCOS

**Prolactinoma Symptoms**
Galactorrhea, visual changes, headache

## Treatment

**Table 4. Management of Amenorrhea**

| Etiology | Management |
|---|---|
| **1° AMENORRHEA** | |
| Androgen insensitivity syndrome | Gonadal resection after puberty |
| | Psychological counselling |
| | Creation of neo-vagina with dilation |
| Anatomical | |
| Imperforate hymen | Surgical management |
| Transverse vaginal septum | Surgical management |
| Cervical agenesis | Suppression and ultimately hysterectomy |
| Müllerian dysgenesis (MRKH syndrome) | Psychological counselling |
| | Creation of neo-vagina with dilation |
| | Diagnostic study to confirm normal urinary system and spine |

**Primary Amenorrhea**
No menses by age 13 in absence of 2° sexual characteristics, or no menses by age 15 with 2° sexual characteristics, or no menses 2 yr after thelarche

**Secondary Amenorrhea**
No menses for >6 mo or 3 cycles after documented menarche

**Table 4. Management of Amenorrhea** (continued)

| Etiology | Management |
|---|---|
| **2° AMENORRHEA** | |
| HP-axis dysfunction | **Identify modifiable underlying cause**<br>Combined OCP to decrease risk of osteoporosis, maintain normal vaginal and breast development (NOT proven to work) |
| Hyperprolactinemia | MRI/CT head to rule out lesion<br>If no demonstrable lesions by MRI<br>Bromocriptine, cabergoline if fertility desired<br>Combined OCPs if no fertility desired<br>Demonstrable lesions by MRI: surgical management |
| Polycystic ovarian syndrome | See *Polycystic Ovarian Syndrome*, GY23 |
| Premature ovarian failure | Screen for DM, hypothyroidism, hypoparathyroidism, hypocorticolism<br>Hormonal therapy with estrogen + progestin to decrease risk of osteoporosis; can use OCP after induction of puberty |
| Uterine defect | Evaluation with hysterosalpingography or sonohysterography |
| Asherman's syndrome | Hysteroscopy: excision of synechiae |

2° amenorrhea is pregnancy until proven otherwise

# Abnormal Uterine Bleeding

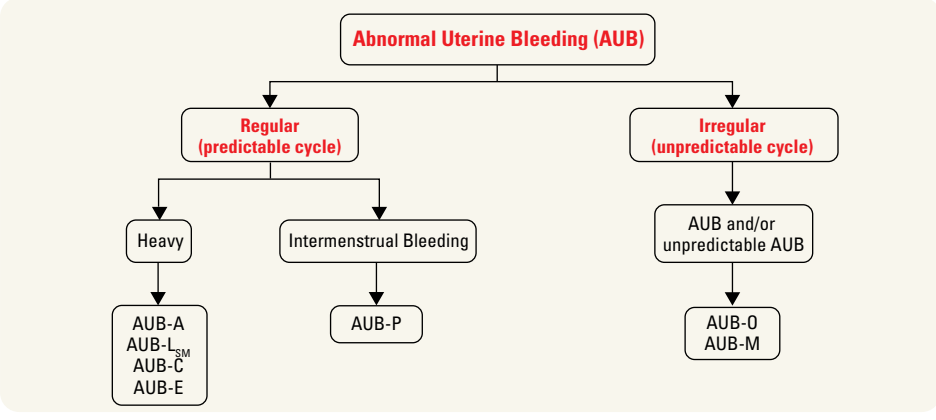

**Figure 7. Diagnostic approach to abnormal uterine bleeding**

## Approach

- menstrual bleeding should be evaluated by ascertaining: frequency/regularity of menses, duration, volume of flow, impact on quality of life, and timing (inter or premenstrual or breakthrough)
- is it regular?
  - regular: cycle to cycle variability of <20 d – "Can you predict your menses within 20 days?"
  - irregular: cycle to cycle variability of ≥20 d
- is it heavy?
  - ≥80 cc of blood loss per cycle or
  - ≥8 d of bleeding per cycle or
  - bleeding that significantly affects quality of life
- is it structural?
  - PALM
- is it non-structural?
  - COEIN

Postmenopausal bleeding is endometrial cancer until proven otherwise

**Abnormal Uterine Bleeding**
Change in frequency, duration, or amount of menstrual flow that affects quality of life

**Table 5. AUB – Etiologies, Investigations, and Management**

| Etiology | Investigations | Management |
|---|---|---|
| | **STRUCTURAL** | |
| **Polyps (AUB-P)** | Transvaginal sonography<br>Saline infusion sonohysterography | Polypectomy (triage based on symptoms,polyp size, histopathology and patient age) |
| **Adenomyosis (AUB-A)** | Transvaginal sonography<br>MRI | See *Adenomyosis*, GY13 |
| **Leiomyoma (AUB-L)**<br>**Submucosal (AUB-Lsm)**<br>**Other (AUB-Lo)** | Transvaginal sonography<br>Saline infusion sonohysterography<br>Diagnostic hysteroscopy | See *Fibroids (Leiomyomata)*, GY13 |
| **Malignancy and Hyperplasia (AUB-M)** | Transvaginal sonography<br>Endometrial biopsy for all women >40 yr with AUB, for women <40 yr with persistent AUB or endometrial cancer risk factors | Dependent on diagnosis |
| | **NON-STRUCTURAL** | |
| **Coagulopathy (AUB-C)** | CBC, coagulation profile (especially in adolescents), vWF, Ristocetin cofactor, factor VIII | Dependent on diagnosis (hormonal modulation (e.g. OCP), Mirena IUS, endometrial ablation) |
| **Ovulatory dysfunction (AUB-O)** | Bloodwork: β-hCG, ferritin, prolactin, FSH, LH, serum androgens (free testosterone, DHEA), progesterone, 17-hydroxy progesterone, TSH, free T4<br>pelvic ultrasound | See *Infertility*, GY22 |
| **Endometrial (AUB-E)** | Endometrial biopsy | Tranexamic acid<br>Hormonal modulation (e.g. OCP)<br>Mirena IUS<br>Endometrial ablation |
| **Iatrogenic (AUB-I)** | Transvaginal sonography (rule out forgotten IUD)<br>Review OCP/HRT use<br>Review meds (especially neuroleptic use) | Remove offending agent |
| **Not yet classified (AUB-N)** | — | — |

## Treatment

- resuscitate patient if hemodynamically unstable
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider AUB
- medical
  - mild AUB
    - NSAIDs
    - anti-fibrinolytic (e.g. Cyklokapron®) at time of menses
    - combined hormonal contraceptive
    - progestins (Provera®) on first 10-14 d of each month or every 3 mo if AUB-O
    - Mirena® IUD
    - correct anemia - iron
  - acute, severe AUB
    - replace fluid losses, consider admission

    a) estrogen (Premarin®) 25 mg IV q4h x 24 h with Gravol® 50 mg IV/PO q4h or anti-fibrinolytic (e.g. Cyklokapron®) 10 mg/kg IV q8h (rarely used)

    b) tapering OCP regimen, 35 μg pill tid x7d then taper to 1 pill/d for 3wk with Gravol® 50 mg IV/PO q4h
      - or taper to 1 tab tid x 2 d → bid x 2 d → OD (more commonly used)
    - after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
      - medical (can also consider):
        - high dose progestins
        - danazol (Danocrine®)
        - GnRH agonsits (e.g. Lupron ®) with add-back if taken for >6 mo
        - ulipristal acetate
- surgical
  - endometrial ablation
    - if finished childbearing
    - repeat procedure may be required if symptom recur, especially if <40 yr
  - hysterectomy: definitive treatment

# Dysmenorrhea

## Etiology
- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g. non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechiae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - pelvic inflammatory disease
  - IUD (copper)
  - foreign body

**Primary Dysmenorrhea**
Recurrent crampy lower abdominal pain during menses in the absence of demonstrable disease

**Secondary Dysmenorrhea**
Pain during menses that can be attributed to an underlying disorder (endometriosis, adenomyosis, fibroids)

**Table 6. Comparison of Primary and Secondary Dysmenorrhea**

| | Primary Dysmenorrhea | Secondary Dysmenorrhea |
|---|---|---|
| **Features** | Recurrent, crampy lower abdominal pain that occurs during menses in the absence of demonstrable disease | Similar features as primary dysmenorrhea but with an underlying disorder that can account for the symptoms, such as endometriosis, adenomyosis or uterine fibroids |
| **Signs and Symptoms** | Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h)<br>Associated symptoms: N/V, altered bowel habits, headaches, fatigue (prostaglandin-associated) | Associated dyspareunia, abnormal bleeding, infertility |
| **Diagnosis** | Assess for associated dyspareunia, abnormal bleeding, infertility (signs of 2° dysmenorrhea)<br>Rule out underlying pelvic pathology and confirm cyclic nature of pain<br>Pelvic examination not required; indicated for patients not responding to therapy or with signs of organic pathology | Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in women <20 yr)<br>U/S, laparoscopy and hysteroscopy may be necessary to establish the diagnosis<br>Vaginal and cervical cultures may be required |
| **Treatment** | Regular exercise, local heat<br>NSAIDs: should be started before onset of pain<br>Combined hormonal contraceptives with continuous or extended use: suppress ovulation/ reduce menstrual flow | Treat underlying cause |

# Endometriosis

## Definition
- the presence of endometrial tissue (glands and stroma) outside of the uterine cavity
- chronic condition, resolving only with menopause

## Etiology
- not fully understood; proposed mechanisms include (combination likely involved):
  - retrograde menstruation (Sampson's theory)
  - immunologic: decreased NK cell activity limiting clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
  - extrapelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

**Differential Diagnoses**
- Chronic PID, recurrent acute salpingitis
- Hemorrhagic corpus luteum
- Benign/malignant ovarian neoplasm
- Ectopic pregnancy

**Classic Triad of Endometriosis**
- Dysmenorrhea
- Dyspareunia (cul-de-sac, uterosacral ligament)
- Dyschezia (uterosacral ligament, cul-de-sac, rectosigmoid attachment)

## Epidemiology
- incidence: 15-30% of pre-menopausal women
- mean age at presentation: 25-30 yr
- regresses after menopause

## Risk Factors
- family history (7-10x increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – resolves with treatment of anomaly
- nulliparity
- age >25 yr

## Sites of Occurrence

- ovaries: 60% patients have ovarian involvement
- broad ligament, vesicoperitoneal fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs

## Clinical Features

- may be asymptomatic and can occur with one of 3 presentations

**1. pain**

- menstrual symptoms
  - cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
  - secondary dysmenorrhea
  - sacral backache with menses
  - pain may eventually become chronic, worsening perimenstrually
  - deep dyspareunia
- bowel and bladder symptoms
  - frequency, dysuria, hematuria
  - cyclic diarrhea/constipation, hematochezia, dyschezia (suggestive of deeply infiltrating disease)

**2. infertility**

- 30-40% of patients with endometriosis will be infertile
- 15-30% of those who are infertile will have endometriosis

**3. mass (endometrioma)**

- ovarian mass can present with any of above symptoms or be asymptomatic
- physical examination:
  - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
  - fixed retroversion of uterus
  - firm, fixed adnexal mass (endometrioma: an endometriotic cyst encompassing ovary)

## Investigations

- definitive diagnosis can be made based on:
  - direct visualization of lesions typical of endometriosis at laparoscopy
  - biopsy and histologic exam of specimens (2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages)
- laparoscopy
  - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac, or anywhere in the pelvis
  - endometrioma: "chocolate" cysts on the ovaries
  - "powder-burn" lesions on the peritoneal surface
  - early white lesions and clear blebs
  - peritoneal "pockets"
- CA-125 (cancer antigen 125)
  - may be elevated in patients with endometriosis but should NOT be used as a diagnostic test

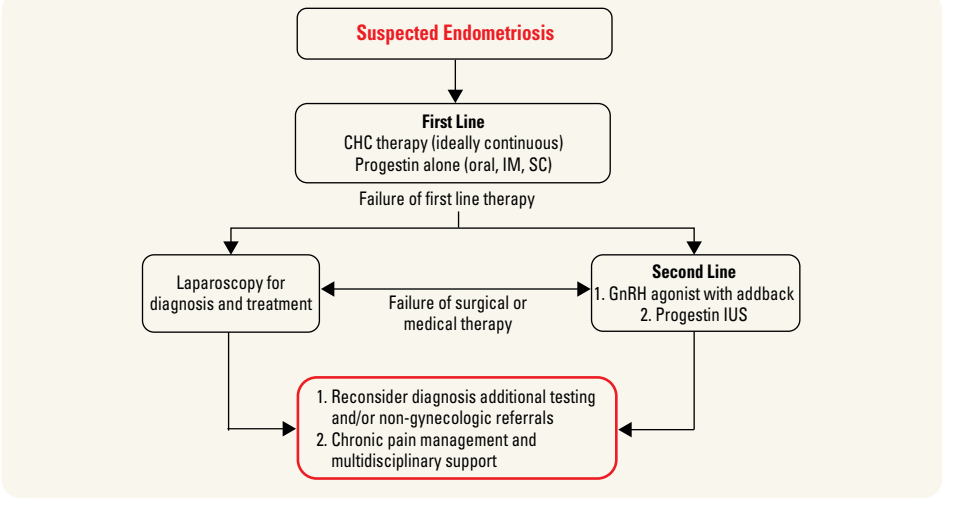

**Figure 8. SOGC guidelines for treatment of endometriosis**

**Endometriosis – Take Home Points**

- Suggestive history even with a negative exam should be considered adequate for a presumptive diagnosis
- Pelvic pain that is not primary dysmenorrhea should be considered endometriosis until proven otherwise
- Medical management is the mainstay of endometriosis

## Treatment

- surgical confirmation of disease is NOT required prior to starting medical management. Asymptomatic endometriosis does not require treatment. Management depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility, and impact to GI/GU systems (e.g. intestinal obstruction)

- medical
  - NSAIDs (e.g. naproxen sodium – Anaprox®)
  - 1st line
    - cyclic/continuous estrogen-progestin (OCP)
    - progestin (IM medroxyprogesterone (Depo-Provera®) or oral dienogest (Visanne®))
    - Mirena® IUS
  - 2nd line
    - GnRH-agonist (e.g. leuprolide (Lupron®)): suppresses pituitary
      - side effects: hot flashes, vaginal dryness, reduced libido
      - use >6 mo: include add-back progestin or estrogen to prevent decreased BMD, reduce vasomotor side-effects
    - danazol (Danocrine®): weak androgen
      - side effects: weight gain, fluid retention, acne, hirsutism, voice change
- surgical
  - conservative laparoscopy using laser, electrocautery ± laparotomy
    - ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
  - definitive: bilateral salpingo-oophorectomy ± hysterectomy
  - best time to become pregnant is immediately after conservative surgery
  - if patient is not planning to become pregnant post-op, suppress ovulation medically to prevent recurrence

# Adenomyosis

- synonym: "endometriosis interna" (uterine wall may be diffusely involved)

**Adenomyosis**
Extension of areas of endometrial glands and stroma into the myometrium

### Epidemiology
- 15% of females >35 yr old; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 yr old (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

### Clinical Features
- often asymptomatic
- heavy menstrual bleeding, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm
- Halban sign: tender, softened uterus on premenstrual bimanual exam

Final diagnosis of adenomyosis is based on pathologic findings, but predictably identified on MRI

### Investigations
- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

### Treatment
- medical
  - iron supplements for anemia
  - analgesics, NSAIDs
  - Mirena® IUS
  - CHC, medroxyprogesterone (Depo-Provera®) – limited evidence for efficacy
  - GnRH agonists (e.g. leuprolide (Lupron ®))
  - low dose danazol 100-200 mg PO OD (trial x 4 mo)
- surgical
  - definitive: hysterectomy – treatment of choice in women who have completed childbearing

# Fibroids

**Leiomyomata/Fibroids**
Benign smooth muscle tumour of the uterus (most common gynecological tumour)

### Epidemiology
- diagnosed in approximately 40-50% of pre-menopausal women >35 yr
- more common in African Americans, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential (1:1000)
- typically regress after menopause

Submucosal leiomyomata are most symptomatic (bleeding, infertility)

### Pathogenesis
- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
  - fibroids can degenerate, become calcified, develop sarcomatous component, or obtain parasitic blood supply

The effect of pregnancy on fibroid size is variable

## Clinical Features

- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S
- abnormal uterine bleeding (30%): dysmenorrhea, heavy menstrual bleeding
- pressure/bulk symptoms (20-50%)
  - pelvic pressure/heaviness
  - increased abdominal girth
  - urinary frequency and urgency
  - constipation, bloating (rare)
  - acute urinary retention (extremely rare, but surgical emergency!)
- acute pelvic pain
  - fibroid degeneration
  - fibroid torsion (if pedunculated subserosal)
- infertility, recurrent pregnancy loss
- pregnancy complications (potential enlargement and increased pain, obstructed labour, difficult C-section)

## Investigations

- bimanual exam: uterus asymmetrically enlarged, usually mobile
- CBC: anemia
- U/S: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids, or for assessing intracavitary growth
- endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if age >40 yr)
- occasionally MRI is used for pre-operative planning (e.g. before myomectomy)

## Treatment

- only if symptomatic (heavy menstrual bleeding, menometrorrhagia, bulk symptoms), rapidly enlarging or intracavitary
- treat anemia if present
- conservative approach (watch and wait) if:
  - symptoms absent or minimal
  - fibroids <6-8 cm or stable in size
  - not submucosal (submucosal fibroids are more likely to be symptomatic)
  - currently pregnant due to increased risk of bleeding (follow-up U/S if symptoms progress)
- medical approach to treat AUB-L
  - antiprostaglandins (ibuprofen, other NSAIDs)
  - tranexamic acid (Cyklokapron®)
  - CHC, IUS or Depo-Provera®
  - GnRH agonist: leuprolide (Lupron®)
    - often used for 3 mo preoperatively to increase Hb and reduce fibroid size
    - reduces bleeding, shrinks fibroids, and corrects anemia
    - can be used long-term to bridge to menopause in combination with add-back progestin or estrogen
  - ulipristal acetate (Fibristal ®): a selective progesterone receptor agonist
    - 5 mg daily for 3 mo
    - reduces bleeding, shrinks fibroids
    - repeat courses only if patient not eligible for surgery; patients must menstruate between courses
    - associated with benign, non-physiological endometrial changes (selective progesterone receptor modulator-associated endometrial changes (PAEC)) which are reversible with discontinuation of therapy
    - note: rare side effect of liver failure. Screen for liver disease prior to prescribing, and monitor liver function before, during, and after treatment courses. Do not prescribe in patients with underlying liver disorder
- interventional radiology approach
  - uterine artery embolization (UAE) occludes both uterine arteries, shrinks fibroids by 50% at 6 mo; improves heavy bleeding in 90% of patients within 1-2 mo; not an option in women considering childbearing
    - higher risk of surgical re-intervention than with surgical approaches
- surgical approach
  - myomectomy (hysteroscopic, transabdominal, or laparoscopic)
  - hysteroscopic resection of fibroid and endometrial ablation for AUB-Lsm
  - hysterectomy (see *Hysterectomy*, GY6)
  - note: avoid operating on fibroids during pregnancy (due to vascularity and potential pregnancy loss); expectant management usually best

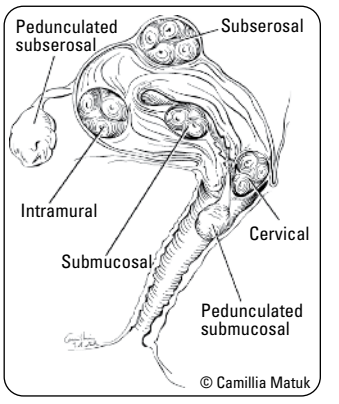

**Figure 9. Possible anatomic locations of uterine leiomyomata**

**Ulipristal Acetate vs. Leuprolide Acetate for Uterine Fibroids**
NEJM 2012;366:421-432
**Study**: Phase III, double-blind RCT of the efficacy and side-effect profile of ulipristal acetate versus those of leuprolide acetate for the treatment of symptomatic uterine fibroids before surgery.
**Outcomes**: Control of uterine bleeding at week 13 was the primary outcome. Secondary outcomes included bleeding pattern, amenorrhea, changes in fibroid/uterine volume, and global pain score.
**Patients**: 307 premenopausal women with symptomatic fibroids and excessive uterine bleeding were randomly assigned to oral ulipristal acetate (5 mg or 10 mg) or intramuscular injections of leuprolide acetate.
**Results**: Control of bleeding at week 13 was not significantly different between the treatment groups. All three treatments reduced uterine volume, although this decrease was significantly greater in the leuprolide group (47% reduction) than in the ulipristal groups (20-22%). 40% of the leuprolide group reported moderate-to-severe hot flashes, but only 11% (5 mg) and 10% (10 mg) of the ulipristal groups did.
**Conclusions**: Oral ulipristal acetate (5 mg or 10 mg) is noninferior to intramuscular leuprolide acetate for control of uterine bleeding due to fibroids and has a better side-effect profile.

**Uterine artery embolization for symptomatic uterine fibroids**
Cochrane Database Syst Rev. 2014, 12: CD005073
**Purpose**: To compare outcomes of uterine artery embolization (UAE) to other medical or surgical therapies for symptomatic uterine fibroids. Primary outcomes were patient satisfaction and live birth rate.
**Results**: Seven RCTs with 793 women were included. There was no evidence of a difference in the primary outcomes or risk of major complications between the interventions. UAE was associated with a higher risk of minor complications and the need for additional surgical intervention within two years.
**Conclusions**: No significant differences in patient satisfaction or major complications in UAE compared to surgical intervention. UAE is associated with an increased risk of surgical re-intervention.

# Contraception

• see Family Medicine, FM20

**Table 7. Classification of Contraceptive Methods**

| Type | Effectiveness (Perfect Use, Typical Use*) |
|---|---|
| **Physiological** | |
| Withdrawal/coitus interruptus | 96%, 77% |
| Rhythm method/calendar/mucus/symptothermal | 76% |
| Lactational amenorrhea | 98% (first 6 mo postpartum) |
| Chance – no method used | 15% |
| Abstinence of all sexual activity | 100% |
| **Barrier Methods** | |
| Condom alone | 98%, 82% |
| Spermicide alone | 82%, 72% |
| Sponge – Parous | 80%, 76% |
| – Nulliparous | 91%, 88% |
| Diaphragm with spermicide | 94%, 88% |
| Female condom | 95%, 79% |
| Cervical cap – Parous | 74%, 68% |
| – Nulliparous | 91%, 84% |
| **Hormonal** | |
| OCP | 99.7%, 92% |
| Nuva Ring® | 99.7%, 92% |
| Transdermal (Ortho Evra®) | 99.7%, 92% |
| Depo-Provera® | 99.7%, 97% |
| Progestin-only pill (Micronor®) | 90-99% |
| Mirena® IUS | 99.9% |
| Jaydess® IUS | 99.9% |
| **Copper IUD** | 99.3% |
| **Surgical** | |
| Tubal ligation | 99.65% |
| Vasectomy | 99.9% |
| **Emergency Postcoital Contraception (EPC)** | |
| Yuzpe® method | 98% (within 24 h), decreases by 30% at 72 h |
| "Plan B" levonorgestrel only | 98% (within 24 h), decreases by 70% at 72 h |
| Postcoital IUD | 99.9% |
| Ella | 98% (within 120 h) |

*Effectiveness: percentage of women reporting no pregnancy after 1 yr of use

**Counselling the Adolescent about Contraception**
More than 90% of adolescent pregnancies are unintended, and ~50% of all pregnancies occur within the first 6 mo of initiating sexual activity; in addition, 85% of sexually active women become pregnant within 1 yr if no contraception is used and even some of the least effective contraceptive methods markedly decrease the risk of pregnancy

**New Oral Contraceptive Preparations and the Risk of Venous Thromboembolism vs. Second Generation Drugs**
BMJ 2015;350:h2135
**Summary**: Risks of thromboembolism associated with combined OCPs were higher for drug preparations with newer progesterone types than for second generation drugs (levonorgestrel and noresthisterone) and norgestimate.
**Methods**: Two nested case-control studies were performed on UK population through two large databases containing total of 1340 practices. Women aged 15-49 years with a first diagnosis of VTE in 2001-13 were matched with five controls by age, practice, and calendar year. OR for VTE incidence and use of combined OCPs were adjusted for smoking status, alcohol consumption, ethnic group, BMI, comorbidities, and other contraceptive drugs.
**Results**: Current exposure to OCP was associated with adjusted OR of 2.97 (95% CI 2.78-3.17) compared to no exposure in previous year. Risks associated with current exposure to new progesterone drug preparations (desogestrel, gestodene, drospirenone, cyproterone) were significantly higher than those for second generation contraceptives (levonorgestrel, noresthisterone) and norgestimate.

# Hormonal Methods

## Combined Oral Contraceptive Pills

- progestin: prevents LH surge, suppresses ovulation, thickens cervical mucus, decreases tubal motility, decidualizes endometrium
- estrogen: suppresses FSH and follicular development, causes endometrial proliferation
- most contain low dose ethinyl estradiol (20-35 μg) plus progestin (norethinedrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
- failure rate (0.3% to 8%) depending on compliance
- monophasic or triphasic formulations (varying amount of progestin throughout cycle)

## Transdermal (Ortho Evra®)

- continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
- applied to lower abdomen, back, upper arm, buttocks, NOT breast
- worn for 3 consecutive weeks (changed every wk) with 1 wk off to allow for menstruation
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in women >90 kg
- may not be covered by drug plans

## Contraceptive Ring (Nuva Ring®)

- thin flexible plastic ring; releases etonogestrel 120 μg/d and estradiol 15 μg/d
- works for 3 wk then removed for 1 wk to allow for menstruation
- as effective as OCP in preventing pregnancy (98%)
- side effects: vaginal infections/irritation, vaginal discharge
- may have better cycle control; i.e. decreased breakthrough bleeding

## Starting Hormonal Contraceptives

- thorough history and physical exam, including blood pressure and breast exam
- can start at any time during cycle but ideal if within 5 d of LMP
- follow-up visit 6 wk after hormonal contraceptives prescribed
- pelvic exam not required as STI screening can be done by urine and pap smear screening does not start until >21 yr

### Table 8. Combined Estrogen and Progestin Contraceptive Methods

| Advantages | Side Effects | Contraindications |
|---|---|---|
| Highly effective<br>Reversible<br>Cycle regulation<br>Decreased dysmenorrhea and heavy menstrual bleeding (less anemia)<br>Decreased benign breast disease and ovarian cyst development<br>Decreased risk of ovarian and endometrial cancer<br>Increased cervical mucus which may lower risk of STIs<br>Decreased PMS symptoms<br>Improved acne<br>Osteoporosis protection (possibly) | **Estrogen-related**<br>Nausea<br>Breast changes (tenderness, enlargement)<br>Fluid retention/bloating/edema<br>Weight gain (rare)<br>Migraine, headaches<br>Thromboembolic events<br>Liver adenoma (rare)<br>Breakthrough bleeding (low estradiol levels)<br><br>**Progestin-related**<br>Amenorrhea/breakthrough bleeding<br>Headaches<br>Breast tenderness<br>Increased appetite<br>Decreased libido<br>Mood changes<br>HTN<br>Acne/oily skin*<br>Hirsutism*<br><br>* Androgenic side effects may be minimized by prescribing formulations containing desogestrel, norgestimate, drospirenone, or cyproterone acetate | **Absolute**<br>Known/suspected pregnancy<br>Undiagnosed abnormal vaginal bleeding<br>Prior thromboembolic events, thromboembolic disorders (Factor V Leiden mutation; protein C or S, or antithrombin III deficiency), active thrombophlebitis<br>Cerebrovascular or coronary artery disease<br>Estrogen-dependent tumours (breast, uterus)<br>Impaired liver function associated with acute liver disease<br>Congenital hypertriglyceridemia<br>Smoker age >35 yr<br>Migraines with focal neurological symptoms (excluding aura)<br>Uncontrolled HTN<br><br>**Relative**<br>Migraines (non-focal with aura <1 h)<br>DM complicated by vascular disease<br>SLE<br>Controlled HTN<br>Hyperlipidemia<br>Sickle cell anemia<br>Gallbladder disease<br><br>**Drug Interactions/Risks**<br>Rifampin, phenobarbital, phenytoin, griseofulvin, primidone, and St. John's wort can decrease efficacy, requiring use of back-up method<br>No evidence of fetal abnormalities if conceived on OCP<br>No evidence that OCP is harmful to nursing infant but may decrease milk production; not recommended until 6 wk postpartum in breastfeeding and non-breastfeeding moms, ideally ≥3 mo postpartum if BF |

### Table 9. Selected Examples of OCPs

| Type | Active Compounds (estriol and progestin derivative) | Advantages | Disadvantages |
|---|---|---|---|
| **Alesse®** | 20 µg ethinyl estradiol and 0.5 mg levonorgestrel | Low dose (20 µg) OCP<br>Less estrogen side effects | Low-dose pills can often result in breakthrough bleeding<br>If this persists for longer than 3 mo, patient should be switched to an OCP with higher estrogen content |
| **Tri-cyclen®** | 35 µg ethinyl estradiol and 0.180/0.215/0.250 mg norgestimate<br>Triphasic oral contraceptive (graduated levels of progesterone) | Low androgenic activity can help with acne | Triphasic OCPs not ideal for continuous use >3 wk in a row (unlike monophasic formulation) |
| **Yasmin® and Yaz®** | Yasmin®: 30 µg ethinyl estradiol + 3 mg drospirenone (a new progestin)<br>Yaz®: 20 µg ethinyl estradiol + 3 mg drospirenone – 24/4-d pill (4 d pill free interval)<br>Drospirenone has antimineralocorticoid activity and antiandrogenic effects | Decreased perception of cyclic weight gain/bloating<br>Fewer PMS symptoms<br>Improved acne | Hyperkalemia (rare, contraindicated in renal and adrenal insufficiency)<br>Check potassium if patient also on ACEI, ARB, K⁺-sparing diuretic, heparin<br>Continue use of spironolactone |

Irregular breakthrough bleeding often occurs in the first few months after starting OCP; usually resolves after three cycles

Progestin only contraceptives must be taken at the same time every day

**Missed Combined OCPs**

**Miss 1 pill in <24 h**
- Take 1 pill ASAP, and the next pill at the usual time

**Miss ≥1 pill in a row in 1st wk**
- Take 1 pill ASAP, and continue taking one pill daily until the end of the pack
- Use back-up contraception for 7 d; EPC may be necessary

**Miss <3 pills in 2nd or 3rd wk of cycle**
- Take 1 pill ASAP, and continue taking one pill daily until the end of the pack
- Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
- Start the next pack immediately after finishing the previous one
- No need for back-up contraception

**Miss ≥3 pills during the 2nd or 3rd wk**
- Take 1 pill ASAP, and continue taking one pill daily until the end of the pack
- Do ot take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
- Start the next pack immediately after finishing the previous one
- Use back-up contraception for 7 d; EPC may be necessary

SOGC Committee Opinion on Missed Hormonal Contraceptives: New Recommendations. *JOGC* 2008;30:1050-1062. http://www.sogc.org/guidelines/documents/gui219ECO0811.pdf

## PROGESTIN-ONLY METHOD

### Table 10. Progestin Only Contraceptive Methods

| Indications | Mechanism of Action | Side Effects | Contraindications |
|---|---|---|---|
| Suitable for postpartum women (does not affect breast milk supply)<br>Women with contraindications to combined OCP (e.g. thromboembolic or myocardial disease)<br>Women intolerant of estrogenic side effects of combined OCPs | Progestin prevents LH surge<br>Thickening of cervical mucus<br>Decrease tubal motility<br>Endometrial decidualization<br>Ovulation suppression – oral progestins (not IM) do not consistently suppress compared to combined OCPs | Irregular menstrual bleeding<br>Weight gain<br>Headache<br>Breast tenderness<br>Mood changes<br>Functional ovarian cysts<br>Acne/oily skin<br>Hirsutism | **Absolute**<br>None |

## SELECTED EXAMPLES OF PROGESTIN-ONLY METHODS

### Progestin-Only Pill ("minipill")

- Micronor® 0.35 mg norethindrone
- must be taken daily at same time of day to ensure reliable effect; no pill free interval
- higher failure rate (1.1-13% with typical use, 0.51% with perfect use) than other hormonal methods
- ovulation inhibited only in 60% of women; most have regular cycles (but may cause oligo/amenorrhea)
- highly effective if also post-partum breastfeeding, or if >35 yr
- relies on the progestin effects on the cervical mucous and endometrial lining

### Depo-Provera®

- injectable depot medroxyprogesterone acetate
- dose 150 mg IM q12-14wk (convenient dosing)
- initiate ideally within 5 d of beginning of normal menses, immediately postpartum in breastfeeding and non-breastfeeding women. Can consider quick start
- irregular spotting progresses to complete amenorrhea in 70% of women (after 1-2 yr of use)
- highly effective 99%; failure rate 0.3%
- suppresses ovulation very effectively
- side effect: decreased bone density (may be reversible) and weight gain
- disadvantage: restoration of fertility may take up to 9 mo

**Missed Progestin-Only Pills >3 h**
Use back-up contraceptive method for at least 48 h; continue to take remainder of pills as prescribed

**Missed Depo-Provera**

- If last injection given 13-14 wk prior: give next injection immediately
- If >14 wk prior, do β-hCG
  - If β-hCG is positive, give EPC and no injection
  - If β-hCG is negative, give next injection right away and:
    - Intercourse occurred in last 5 d: give EPC, use back-up contraception for 7 d ; repeat β-hCG in 3 wk
    - Intercourse occurred >5 d ago but within the last 14 d: use back-up contraception for 7 d; repeat β-hCG in 3 wk
    - Intercourse occurred >14 d ago: use back-up contraception for 7 d
  - No evidence of fetal abnormalities if conceived on DMPA

SOGC Committee Opinion on Missed Hormonal Contraceptives: New Recommendations.
*JOGC* 2008;30:1050-62. http://www.sogc.org/guidelines/documents/gui219ECO0811.pdf

# Intrauterine Device

**Table 11. IUS/IUD Contraceptive Methods**

| Mechanism of Action | Side Effects | Contraindications |
|---|---|---|
| **Copper-Containing IUD (Nova-T®):** mild foreign body reaction in endometrium; toxic to sperm and alters sperm motility<br><br>**Progesterone-Releasing IUS (MirenaV, Kyleena®, Jaydess®):** decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation<br><br>Highly effective (95-99%); failure rate 0-1.2%<br>Contraceptive effects last 5 yr<br>Reversible, private, convenient<br>May be used in women with contraindications to OCPs or wanting long-term contraception | **Both Copper and Progesterone IUD**<br>Breakthrough bleeding<br>Expulsion (5% in the 1st yr, greatest in 1st mo and in nulliparous women)<br>Uterine wall perforation (1/1000) on insertion<br>If pregnancy occurs with an IUD, increased risk of ectopic<br>Increased risk of PID (within first 10 d of insertion only)<br><br>**Copper IUD:** increased blood loss and duration of menses, dysmenorrhea<br><br>**Progesterone IUD:** bloating, headache | **Absolute**<br>**Both Copper and Progesterone IUD**<br>Known or suspected pregnancy<br>Undiagnosed genital tract bleeding<br>Acute or chronic PID<br>Lifestyle risk for STIs*<br><br>**Copper IUD**<br>Known allergy to copper<br>Wilson's disease<br><br>**Relative**<br>**Both Copper and Progesterone IUD**<br>Valvular heart disease<br>Past history of PID or ectopic pregnancy<br>Presence of prosthesis<br>Abnormalities of uterine cavity, intracavitary fibroids<br>Cervical stenosis<br>Immunosuppressed individuals (e.g. HIV)<br>**Copper IUD**<br>Severe dysmenorrhea or heavy menstrual bleeding |

*Cervical swabs for gonorrhea and chlamydia should be done prior to insertion

**Continuous or Extended Cycle vs. Cyclic Use of Combined Hormonal Contraceptives for Contraception**
Cochrane DB Syst Rev 2014:7
**Purpose**: Systematic review of RCTs assessing the efficacy and side effects of cyclic administration vs. extended use (longer periods of active pills and/or shorter periods placebo) or continuous use (uninterrupted active pill administration) of combination oral contraceptives (COC).
**Results**: The initial review published in 2012 identified 12 RCTs that ultimately showed no difference between groups with regards to efficacy (pregnancy rates), safety, and compliance rates. Continuous or extended CHCs were shown to reduce menstrual symptoms (headaches, tiredness, bloating, and menstrual pain). In addition, 11 of 12 studies reported similar or improved bleeding patterns with continuous or extended cycles.
**Conclusions**: This recently published updated systematic review identified a further 4 RCTs, however, results did not change.

**Committee Opinion No. 602: Depot Medroxyprogresterone Acetate and Bone Effects**
Obstet Gynecol 2014(6):1298-402

- The effect of DMPA on BMD should neither prevent practitioners from prescribing DMPA nor limit its use to 2 consecutive yr.
- BMD loss due to DMPA appears to be substantially or fully reversible.
- Contraceptive implants and intrauterine devices that do not affect BMD should be considered as first-line for adolescents.
- Inform patients about benefits and the potential risks of DMPA, and encourage daily exercise, calcium and vitamin D intake.
- Routine BMD monitoring is not recommended for DMPA users.

# Emergency Postcoital Contraception

**Table 12. Emergency Contraceptive Methods**

| Method | Mechanism of Action | Side Effects | Contraindications |
|---|---|---|---|
| **HORMONAL** | | | |
| **Yuzpe Method**<br>Used within 72 h of unprotected intercourse; limited evidence of benefit up to 5 d<br>Ovral® 2 tablets then repeat in 12 h (ethinyl estradiol 100 µg/ levonorgestrel 500 µg)<br>Can substitute with any OCP as long as same dose of estrogen used<br>2% overall risk of pregnancy<br>Efficacy decreased with time (e.g. less effective at 72 h than 24 h) | Unknown; theories include:<br>Suppresses ovulation or causes deficient luteal phase<br>Alters endometrium to prevent implantation<br>Affects sperm/ova transport | Nausea (due to estrogen; treat with Gravol®)<br>Irregular spotting | Pre-existing pregnancy (although not teratogenic)<br>Caution in women with contraindications to OCP (although NO absolute contraindications) |
| **"Plan B"**<br>Consists of levonorgestrel 750 µg q12h for 2 doses (can also take 2 doses together); taken within 72 h of intercourse. Can be taken up to 5 d<br>Greater efficacy (75-95% if used within 24 h) and better side effect profile than Yuzpe method but efficacy decreases with time; 1st line if >24 h<br>No estrogen thus very few contraindications/side effects (less nausea)<br>Less effective in overweight individuals (>75 kg less effective, >80 kg not recommended) | Same as above | Same as above | Same as above but no caution in women with contraindications to OCP |
| **Ulipristal**<br>30 mg PO within 5 d | Selective Progesterone Receptor Modulator (SPERM) with primarily antiprogestin activity: may delay ovulation by up to 5 d | Headache, hot flashes, constipation, vertigo, endometrial thickening | Same as above but no caution in women with contraindications to OCP |
| **NON-HORMONAL** | | | |
| **Postcoital IUD (Copper)**<br>Insert up to 7 d postcoitus<br>Prevents implantation<br>1% failure rate<br>Can use for short duration in higher risk individuals<br>Mirena® IUS cannot be used as EPC | See Table 11 | See Table 11 | See Table 11 |

## Follow-up

- 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counselling

# Termination of Pregnancy

There is no association between termination of pregnancy and either future breast cancer or future development of psychiatric disease

## Indications

- patient desires an end to pregnancy
- may be for medical reasons (mother or fetus unhealthy) or social reasons, including patient request

## Legal Issues

- no current law in Canada concerning abortion therefore considered legal at any gestational age
- CPSO: a physician must refer for abortion services regardless of personal beliefs, but not compelled to perform procedure

## Rates

- 13.1 abortions/1000 women aged 15-44 in Canada (2017 CIHI data)
- worldwide: 42 million induced abortions per year; half are unsafe (WHO data)
- maternal mortality almost zero where induced abortion is safe and legal; rises to 100 maternal deaths/100,000 live births in sub-Saharan Africa and other countries where abortion is illegal and unsafe
- in Canada, 91% of induced abortions occur <12 wk GA; very rare after 24 wk (usually only for maternal/fetal reasons)

## Methods of induced abortion

- medical
  - gold standard up to 9 wk GA: mifepristone and misprostol : 95-98% effective
  - mifepristone blocks the progesterone receptor (progesterone required in early pregnancy)
  - misoprostol induces uterine contractions
  - can also use misoprostol alone or methotrexate and misoprostol (with lower success rates of 90-95%)
  - side effects: bleeding (self-limited) and pain (while tissue passes) are expected side effects

- surgical
  - <14 wk:
    - manual vacuum aspiration – up to about 8-9 wk with hand held aspiration device
    - suction dilatation + aspiration ± curettage – may involve pre-surgical preparation of cervix with laminaria tents and/or misoprostol
  - 14-24 wk: dilatation and evacuation; pre- surgical preparation of cervix required with laminaria tents
  - pain or discomfort during procedure mitigated by use of appropriate analgesia/sedation/anesthesia (including paracervical blocks)
  - rare complications (1-5%): laceration of cervix, infection/endometritis, retained products of conception, ongoing pregnancy
  - very rare complications: (0.1-2%) : hemorrhage, perforation of uterus, Asherman's syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), future preterm birth (controversial and likely only with repeated abortion)
- counselling
  - options counselling always provided; always offer possibility of carrying pregnancy with/without adoption
  - offer future contraception and family planning services
  - ensure follow-up

# Pregnancy-Related Complications

## First and Second Trimester Bleeding

### Approach to the Patient with Bleeding in T1/T2

#### History
- risk factors for ectopic pregnancy (see *Ectopic Pregnancy*, GY20)
- previous spontaneous abortion
- recent trauma
- characteristics of the bleeding (including any tissue passed)
- characteristics of the pain (cramping pain suggests spontaneous abortion)
- history of coagulopathy
- gynecological/obstetric history
- fatigue, dizziness, syncopal episodes due to hypovolemia, fever (may be associated with septic abortion)

#### Physical
- vitals (including orthostatic changes)
- abdomen (symphysis fundal height, tenderness, presence of contractions)
- perineum (signs of trauma, genital lesions)
- speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
- pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness, cervical motion tenderness)

#### Investigations
- β-hCG (may be lower than expected for GA in spontaneous abortion, can be used to diagnose viable pregnancy vs. ectopic pregnancy vs. abortion)
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

#### Treatment
- IV resuscitation for hemorrhagic shock
- treat the underlying cause

**Bleeding in Pregnancy Definitions**
- First trimester bleeding: vaginal bleeding within the first 12 wk
- Second trimester bleeding: 12-20 wk

**Differential Diagnosis**
- Physiologic bleeding: spotting, due to implantation of placenta – reassure and check serial β-hCGs
- Abortion (threatened, inevitable, incomplete, complete)
- Abnormal pregnancy (ectopic, molar) (see *Hydatidiform Mole*, GY49)
- Trauma (post-coital or after pelvic exam)
- Genital lesion (e.g. cervical polyp, neoplasms)
- Subchorionic hematoma

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have β-hCG measured

# Spontaneous Abortions

- see *Termination of Pregnancy* for therapeutic abortions, GY18

**Table 13. Classification of Spontaneous Abortions**

| Type | History | Clinical | Management (± Rhogam®) |
|---|---|---|---|
| **Threatened** | Vaginal bleeding ± cramping | Cervix closed and soft | Watch and wait<br><5% go on to abort |
| **Inevitable** | Increasing bleeding and cramps ± rupture of membranes | Cervix closed until products start to expel, then external os opens | a) Watch and wait<br>b) Mifepristone 200 mg PO followed by Misoprostol 800 µg PV 24 h later<br>c) D&C |
| **Incomplete** | Extremely heavy bleeding and cramps ± passage of tissue noticed | Cervix open | a) Watch and wait<br>b) Mifepristone 200 mg PO followed by Misoprostol 800 µg PV 24 h later<br>c) D&C |
| **Complete** | Bleeding and complete passage of sac and placenta | Cervix closed, bleeding stopped | No D&C – expectant management |
| **Missed** | No bleeding (fetal death in utero) | Cervix closed | a) Watch and wait<br>b) Mifepristone 200 mg PO followed by Misoprostol 800 µg PV 24 h later<br>c) D&C |
| **Recurrent** | ≥3 consecutive spontaneous abortions | | Evaluate mechanical, genetic, environmental, and other risk factors |
| **Septic** | Contents of uterus infected – infrequent | | IV broad spectrum antibiotics and prompt uterine evacuation |

Embryonic demise can be diagnosed by ultrasound based on an intrauterine gestational sac, embryonic crown-rump length ≥7 mm, and no cardiac activity

# Ectopic Pregnancy

## Definition

- embryo implants outside of the endometrial cavity

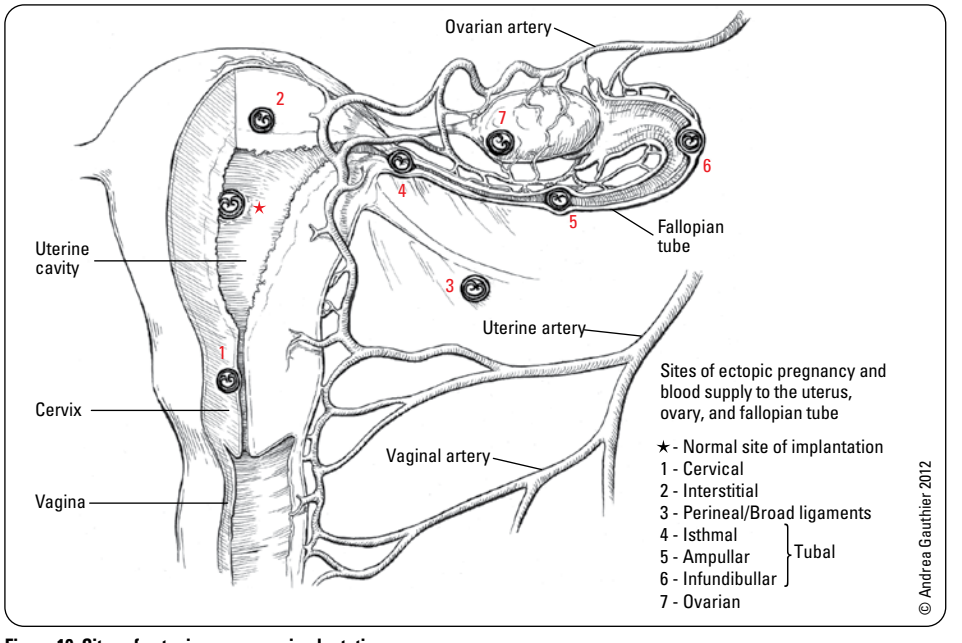

**Figure 10. Sites of ectopic pregnancy implantation**
ampullary (70%) >> isthmal (12%) > fimbrial (11%) > ovarian (3%) > interstitial (2%) > abdominal (1%)

## Epidemiology

- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of maternal death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%)

## Etiology

- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle
- transmigration of fertilized ovum to contralateral tube

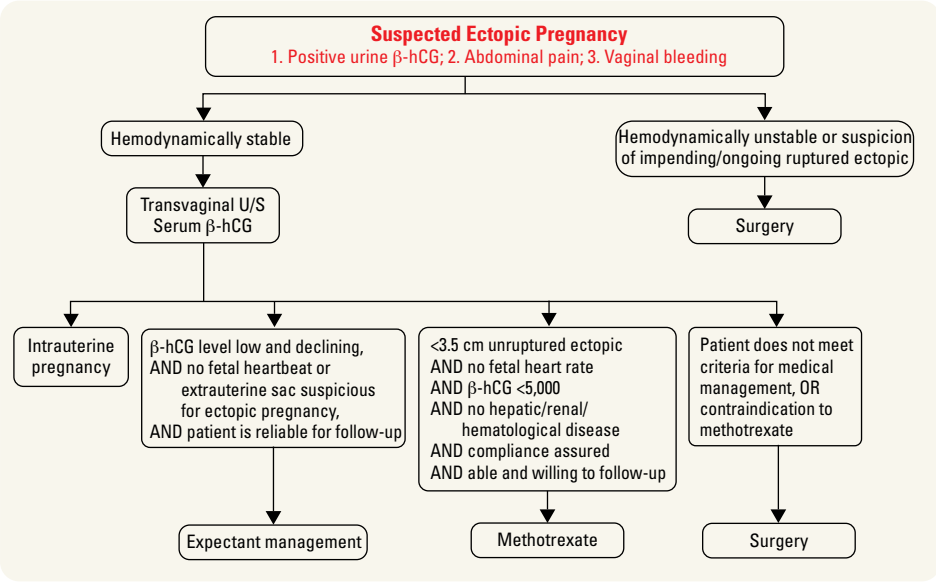

**Figure 11. Algorithm for suspected ectopic pregnancy**

## Risk Factors

- previous ectopic pregnancy
- gynecologic
  - current IUD use – increased risk of ectopic if pregnancy occurs
  - history of PID (especially infection with *C. trachomatis*), salpingitis
  - infertility
- infertility treatment (IVF pregnancies following ovulation induction (7% ectopic rate))
- previous procedures
  - any surgery on fallopian tube (for previous ectopic, tubal ligation, etc.)
  - abdominal surgery for ruptured appendix, etc.
- smoking
- structural
  - uterine leiomyomas
  - adhesions
  - abnormal uterine anatomy (e.g. T-shaped uterus)

## Investigations

- serial β-hCG levels; normal doubling time with intrauterine pregnancy is 1.6-2.4 d in early pregnancy
  - rise of <20% of β-hCG (1.6-2.4 d) is 100% predictive of a non-viable pregnancy
  - prolonged doubling time, plateau, or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal β-hCG doubling
- ultrasound
  - U/S is only definitive if fetal cardiac activity is detected in the tube or uterus
  - specific finding on transvaginal U/S is a tubal ring
- suspect ectopic in case of empty uterus by TVUS with β-hCG >2000-3000 mIU/ml
- laparoscopy (sometimes used for definitive diagnosis)

## Treatment

- goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
- surgical = laparoscopy
  - linear salpingostomy an option if tube salvageable, however, patient must be reliable to follow-up with weekly β-hCG
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence
  - 15% risk of persistent trophoblast if salpingectomy; must monitor β-hCG titres weekly until they reach non-detectable levels
  - consider Rhogam® if Rh negative
  - patient may require laparotomy if unstable, extensive abdominal surgical history, etc.
- medical = methotrexate
  - use 50 mg/m$^2$ body surface area; given in a single IM dose
  - this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic dysfunction, diarrhea, gastritis, dermatitis)
  - follow β-hCG levels weekly until β-hCG is non-detectable
    - plateaued or rising levels suggest persistent trophoblastic tissue requiring further treatment

**Contraindications to Methotrexate Therapy for Ectopic Pregnancy**

- Abnormalities in hematologic, hepatic or renal function
- Immunodeficiency
- Active pulmonary disease
- Peptic ulcer disease
- Hypersensitivity to methotrexate
- Heterotopic pregnancy with coexisting viable intrauterine pregnancy
- Breastfeeding
- Unwilling or unable to adhere to methotrexate protocol

**DDx of Lower Abdominal Pain**

- Urinary tract: UTI, kidney stones
- GI: diverticulitis, appendicitis
- Gyne: endometriosis, PID, fibroid (degenerating, infarcted, torsion), ovarian torsion, ovarian neoplasm, ovarian cyst, pregnancy-related

Any woman presenting with abdominal pain, vaginal bleeding and amenorrhea is an ectopic pregnancy until proven otherwise

More than half of patients with ectopic pregnancy have no risk factors

**Presentation of Ectopic Pregnancy Ruptures**

- Acute abdomen with increasing pain
- Abdominal distention
- Shock

**Management of Abortions**

- Always rule out an ectopic
- Always check Rh; if negative, give Rhogam®
- Always ensure patient is hemodynamically stable

  - 82-95% success rate, but up to 25% will require a second dose
    - administer a second dose if β-hCG does not decrease by at least 15% between days 4 and 7
  - tubal patency following methotrexate treatment approaches 80%
- expectant management is an option for patients who are clinically stable, reliable for follow-up, and have β-hCG levels that are low and declining

### Prognosis
- 9% of maternal deaths during pregnancy attributed to ectopic pregnancy
- 40-60% of patients will become pregnant again after surgery
- 10-20% will have subsequent ectopic pregnancy

# Infertility

### Epidemiology
- 10-15% of couples, must investigate both members of the couple

## Female Factors

### Etiology
- ovulatory dysfunction (15-20%)
  - hypothalamic (hypothalamic amenorrhea)
    - stress, poor nutrition, excessive exercise (even with presence of menstruation), history of eating disorders
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - primary ovarian insufficiency
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
  - systemic diseases (thyroid, Cushing's syndrome, renal/hepatic failure), diabetes
  - congenital (Turner's syndrome, gonadal dysgenesis, or gonadotropin deficiency)
- outflow tract abnormality (15-20%)
  - tubal factors (20-30%)
    - PID
    - adhesions (previous surgery, peritonitis, endometriosis)
    - ligation/occlusion (e.g. previous ectopic pregnancy)
  - uterine factors (<5%)
    - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure, intrauterine adhesions (e.g. Asherman's syndrome), fibroids/polyps (particularly intrauterine)
    - infection (endometritis, pelvic tuberculosis)
    - endometrial ablation
  - cervical factors (5%)
    - hostile or acidic cervical mucus, anti-sperm antibodies
    - structural defects (cone biopsies, laser or cryotherapy)
- endometriosis (15-30%)
- multiple factors (30%)
- unknown factors (10-15%)

### Investigations
- ovulatory
  - day 3: FSH, LH, TSH, prolactin ± DHEA, free testosterone (if hirsute) add estradiol for proper FSH interpretation
  - day 21-23: serum progesterone to confirm ovulation
  - initiate basal body temperature monitoring (biphasic pattern)
  - postcoital test: evaluate mucus for clarity, pH, spinnbarkeit/fibrosity (rarely done)
- tubal factors
  - HSG (can be therapeutic – opens fallopian tube)
  - SHG (can be therapeutic; likely less – opens fallopian tube)
  - laparoscopy with dye insufflation (or tubal dye test) rarely done as diagnostic
- peritoneal/uterine factors
  - HSG/SHG, hysteroscopy
- other
  - karyotype

Infertility: inability to conceive or carry to term a pregnancy after one year of regular, unprotected intercourse
**Primary infertility**: infertility in the context of no prior pregnancies
**Secondary infertility**: infertility in the context of a prior conception
Generally, 75% of couples achieve pregnancy within 6 mo, 85% within 1 yr, 90% within 2 yr

**When Should Investigations Begin?**
- <35 yr: after 1 yr of regular unprotected intercourse
- 35-40 yr: after >6 mo
- >40 yr: immediately
- Earlier if
  - History of PID
  - History of infertility in previous relationship
  - Prior pelvic surgery
  - Chemotherapy/radiation in either partner
  - Recurrent pregnancy loss
- Moderate-severe endometriosis

**Ethical Considerations in Infertility Treatment**
- Infertility demands non-judgmental discussion
- Ethical issues surrounding therapeutic donor insemination in same sex couples, surrogacy, donor gametes, and other advanced reproductive technologies are still evolving and remain controversial
- If the doctor finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician

### Treatment
- education: timing intercourse relative to ovulation (from 2 d prior to 2 d following presumed ovulation), every other day
- medical
  - ovulation induction
    - clomiphene citrate (Clomid®): estrogen antagonist causing a perceived decreased estrogen state, resulting in increased pituitary gonadotropins; which increases FSH and LH and induces ovulation (better results if anovulatory)
    - followed by β-hCG for stimulation of ovum release
    - Letrozole: aromatase inhibitor. May be associated with a higher rate of live births in patients with PCOS
  - may add:
    - bromocriptine (dopamine agonist) if elevated prolactin
    - dexamethasone for hyperandrogenism (adult onset congenital adrenal hyperplasia)
    - metformin (for PCOS)
    - luteal phase progesterone supplementation for luteal phase defect (mechanism not completely understood)
    - anticoagulation and ASA (81 mg PO OD) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
    - thyroid replacement to keep TSH <2.5
- surgical/procedural
  - tubuloplasty
  - lysis of adhesions
  - artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intrauterine tuboperitoneal insemination (IUTPI), intratubal insemination (ITI)
  - sperm washing
  - IVF ( fertilization)
  - IFT (intrafallopian transfer)
  - GIFT* (gamete intrafallopian transfer): immediate transfer with sperm after oocyte retrieval
  - ZIFT* (zygote intrafallopian transfer): transfer after 24 h culture of oocyte and sperm
  - TET* (tubal embryo transfer): transfer after >24 h culture
  - ICSI (intracytoplasmic sperm injection)
  - IVM (in vitro maturation)
  - ± oocyte or sperm donors
  - ± pre-genetic screening for single gene defects in karyotype of zygote

*not performed in Canada

# Male Factors

- see Urology, U36

### Etiology
- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)

### Investigations
- semen analysis and culture
- postcoital (Huhner) test: rarely done

**Normal Semen Analysis (WHO lower reference limits)**
- Must be obtained after 2-7 d of abstinence
  - Volume 1.5 cc
  - Count 15 million/cc
  - Vitality 58% live
  - Motility 32% progressive, 40% total (progressive + non-progressive)
- Morphology 4.0% normal

# Polycystic Ovarian Syndrome

- also called chronic ovarian androgenism

### Etiology

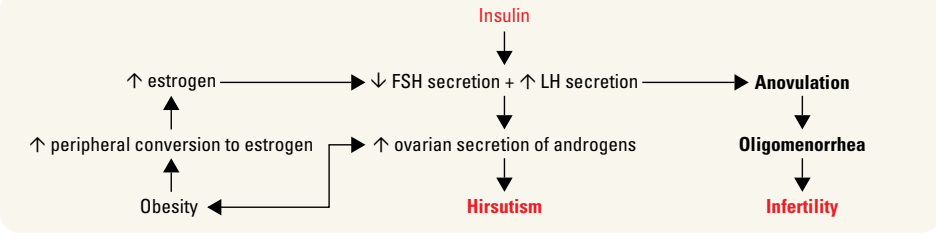

**Figure 12. Pathophysiology of polycystic ovarian syndrome**

**Polycystic Ovarian Syndrome – HAIR-AN**
**H**irsutism, **H**yper**A**ndrogenism, **I**nfertility, **I**nsulin **R**esistance, **A**canthosis **N**igricans

## Diagnosis

- Rotterdam diagnostic criteria: 2 of 3 required
  - oligomenorrhea/irregular menses for 6 mo
  - hyperandrogenism
    - clinical evidence - hirsutism or acne
    - biochemical evidence - raised free testosterone
  - polycystic ovaries on U/S (not appropriate in adolescents)

## Clinical Features

- average age 15-35 yr at presentation
- in adolescents, wait at least 1-2 yr to make diagnosis as adolescence resembles PCOS
- abnormal/irregular uterine bleeding, hirsutism, infertility, obesity, virilization
- acanthosis nigricans: browning of skin folds in intertriginous zones (indicative of insulin resistance)
- insulin resistance occurs in both lean and obese patients
- family history of DM

## Investigations

- goal: identify hyperandrogenism or chronic anovulation and rule out specific pituitary or adrenal disease as the cause
- laboratory
  - prolactin, 17-hydroxyprogesterone, free testosterone, DHEA-S, TSH, free T4, androstenedione, SHBG
  - LH:FSH >2:1; LH is chronically high with FSH mid-range or low (low sensitivity and specificity)
  - increased DHEA-S, androstenedione and free testosterone (most sensitive), decreased SHBG
- transvaginal or transabdominal U/S: polycystic-appearing ovaries ("string of pearls" – 12 or more small follicles 2-9 mm, or increased ovarian volume)
- tests for insulin resistance or glucose tolerance
  - fasting glucose:insulin ratio <4.5 is consistent with insulin resistance (U.S. units)
  - 75 g OGTT yearly (particularly if obese)
- laparoscopy
  - not required for diagnosis
  - most common to see white, smooth, sclerotic ovaries with a thick capsule; multiple follicular cysts in various stages of atresia; and hyperplastic theca and stroma
- rule out other causes of abnormal bleeding

## Treatment

- cycle control
  - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
  - OCP monthly or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
  - oral hypoglycemic (e.g. metformin) if type 2 diabetic or if trying to become pregnant
  - tranexamic acid (Cyklokapron®) for menorrhagia only
- infertility
  - medical induction of ovulation: letrozole, clomiphene citrate (no longer available in Canada), human menopausal gonadotropins (HMG [Pergonal®]), LHRH, recombinant FSH, and metformin
    - metformin may be used alone or in conjuction with clomiphene citrate for ovulation induction
  - ovarian drilling (perforate the stroma), wedge resection of the ovary
  - bromocriptine (if hyperprolactinemia)
- hirsutism
  - any OCP can be used
    - Diane 35® (cyproterone acetate): antiandrogenic
    - Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
  - mechanical removal of hair
  - finasteride (5-α reductase inhibitor)
  - flutamide (androgen reuptake inhibitor)
  - spironolactone: androgen receptor inhibitor

**PCOS May be Confused with**

- Late onset congenital adrenal hyperplasia (21-hydroxylase deficiency)
- Cushing's syndrome
- Ovarian and adrenal neoplasms
- Hyperprolactinemia
- Hypothyroidism

**Clinical Signs of Endocrine Imbalance**

- Menstrual disorder/amenorrhea (80%)
- Infertility (74%)
- Hirsutism (69%)
- Obesity (49%)
- Impaired glucose tolerance (35%)
- DM (10%)

**Long-Term Health Consequences**

- Hyperlipidemia
- Adult-onset DM
- Endometrial hyperplasia
- Infertility
- Obesity
- Sleep apnea

**Insulin-Sensitising Drugs (metformin, rosiglitazone, pioglitazone, D-chiro-inositol) for Women with Polycystic Ovary Syndrome, Oligo Amenorrhoea and Subfertility**

Cochrane Database Syst Rev 2012; (5):CD003053

**Purpose**: To evaluate efficacy of insulin-sensitising drugs in improving reproductive outcomes of women with PCOS.

**Methods**: 42 RCTs (n=3992) were included.

**Conclusions**: Metformin was associated with improved clinical pregnancy rates whether used alone or in combination with clomiphene. However, this did not translate into live birth rates.

**Diagnostic Criteria for Polycystic Ovary Syndrome: Pitfalls and Controversies**

JOGC 2008;8:671-679

At present, there is no clear-cut definition of biochemical hyperandrogenemia, particularly since there is dependence on poor laboratory standards for measuring androgens in women. Clinical signs of hyperandrogenism are ill-defined in women with PCOS, and diagnosis of both hirsutism and polycystic ovarian morphology remains subjective. There is also the inappropriate tendency to assign ovulatory status solely on basis of menstrual cycle history or poorly timed endocrine measurements. Therefore it is important as clinicians to recognize the multi-factorial and complex nature of PCOS and place this in the context of our present diagnostic limitations.

# Gynecological Infections

## Physiologic Discharge

- clear, white, flocculent, odourless discharge; pH 3.8-4.2
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS, or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

## Pruritus

- can be caused by physiologic discharge and cervical mucus production
- non-physiologic
  - genital tract infection
  - vulvovaginitis: candidiasis, trichomoniasis, BV, polymicrobial superficial infection
  - chlamydia, gonorrhea
  - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)

## Vulvovaginitis

### PREPUBERTAL VULVOVAGINITIS

- clinical features: irritation, pruritus, discharge, vulvar erythema, vaginal bleeding (specifically due to Group A Streptococci and Shigella)
- etiology
  - poor hygiene (proximity of anus to vagina)
  - foreign bodies (most commonly tissue paper)
  - irritation by perfumed soaps, chemicals, and tight clothing
  - localized skin disorders: lichen sclerosis, condyloma acuminata
  - trauma: accidental straddle injury, sexual abuse
  - infectious
    - pinworms
    - Candida (if using diapers or chronic antibiotics)
    - Group A streptococcus, *S. aureus* and *Shigella*
    - discovery of STI should raise suspicion of sexual abuse
  - other
    - polyps, tumour (ovarian malignancy)
    - psychosomatic vaginal complaints (specific to vaginal discharge)
    - endocrine abnormalities (specific to vaginal bleeding)
    - blood dyscrasia (specific to vaginal bleeding)
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen)
  - pH, wet-mount, and KOH smear in prepubertal adults only
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, no nylon tights, no tight fitting clothes, no sleeper pajamas, sitz baths, avoid bubble baths, use mild detergent, eliminate fabric softener, avoid prolonged exposure to wet bathing suits, urination with legs spread apart)
  - A&D® dermatological ointment (vitamin A/D) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

**Table 14. Other Common Causes of Vulvovaginitis in Prepubertal Girls**

| | Pinworms | Lichen Sclerosis | Foreign Body |
|---|---|---|---|
| **Diagnosis** | Cellophane tape test | Area of white patches and thinning of skin (figure of 8) | |
| **Treatment** | Empirical treatment with mebendazole | Topical steroid creams | Irrigation of vagina with saline, may require local anesthesia or an exam under anesthesia |

**Vulvovaginitis**
Vulvar and vaginal inflammation

**Prepubertal and Adolescent Gynecological Infections: Legal Aspects of Confidentiality**
- Clinicians who treat adolescents must be aware of federal, state, and provincial laws related to adolescent consent and confidentiality
- Cllinicians must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice

There is no high quality evidence showing a link between vulvovaginal candidiasis and hygienic habits or wearing tight or synthetic clothing

Most common gynecological problem in prepubertal girls is non-specific vulvovaginitis, not yeast

## INFECTIOUS VULVOVAGINITIS

**Table 15. Infectious Vulvovaginitis**

| | Candidasis | Bacterial Vaginosis (BV) | Trichomoniasis |
|---|---|---|---|
| **Organisms** | *Candida albicans* (90%)<br>*Candida glabrata* (<5%)<br>*Candida tropicalis* (<5%) | *Gardnerella vaginalis*<br>*Mycoplasma hominis*<br>Anaerobes: *Prevotella, Mobiluncus, Bacteroides* | *Trichomonas vaginalis* (flagellated protozoan) |
| **Pathophysiology or Transmission** | Predisposing factors include:<br>Immunosuppressed host (DM, AIDS, etc.)<br>Recent antibiotic use<br>Increased estrogen levels (e.g. pregnancy, OCP) | Replacement of vaginal *Lactobacillus* with organisms above | Sexual transmission |
| **Discharge** | Whitish, "cottage cheese," minimal | Grey, thin, diffuse | Yellow-green, malodourous, diffuse, frothy |
| **Other** | 20% asymptomatic | 50-75% asymptomatic | 25% asymptomatic |
| **Signs/Symptoms** | Intense pruritus<br>Swollen, inflamed genitals<br>Vulvar burning, dysuria, dyspareunia | Fishy odour, especially after coitus<br>Absence of vulvar/vaginal irritation | Petechiae on vagina and cervix<br>Occasionally irritated, tender vulva<br>Dysuria, frequency |
| **pH** | ≤4.5 | ≥4.5 | ≥4.5 |
| **Saline Wetmount** | KOH wetmount reveals hyphae and spores | >20% clue cells = squamous epithelial cells dotted with coccobacilli (*Gardnerella*)<br>Paucity of WBC<br>Paucity of *Lactobacilli*<br>Positive whiff test: fishy odour with addition of KOH to slide (due to formation of amines) | Motile flagellated organisms<br>Many WBC<br>Inflammatory cells (PMNs)<br>Can have positive whiff test |
| **Treatment** | Clotrimazole, butoconazole, miconazole, terconazole suppositories, and/or creams for 1, 3, or 7 d treatments<br>Treatment in pregnancy is usually topical<br>Fluconazole 150 mg PO in single dose (can be used in pregnancy) | No treatment if non-pregnant and asymptomatic, unless scheduled for pelvic surgery or procedure<br>**Oral**<br>Metronidazole 500 mg PO bid x 7 d<br>**Topical**<br>Metronidazole gel 0.75% x 5 d OD (may be used in pregnancy)<br>Clindamycin 2% 5 g intravaginally at bedtime for 7 d<br>Probiotics (*Lactobacillus* sp.): oral or topical alone or as adjuvant | Treat even if asymptomatic<br>Metronidazole 2 g PO single dose or 500 mg bid x 7 d (alternative)<br>Symptomatic pregnant women should be treated with 2 g metronidazole once |
| **Other** | Prophylaxis for recurrent infection includes boric acid, vaginal suppositories, luteal phase fluconazole<br>Routine treatment of partner(s) not recommended (not sexually transmitted) | Associated with recurrent preterm labour, preterm birth, and postpartum endometritis<br>Need to warn patients on metronidazole not to consume alcohol (disulfiram-like action)<br>Routine treatment of partner(s) not recommended (not sexually transmitted) | Warnings accompanying metronidazole use<br>Treat partner(s) (sexually transmitted) |

# Sexually Transmitted Infections

• see Family Medicine, FM42

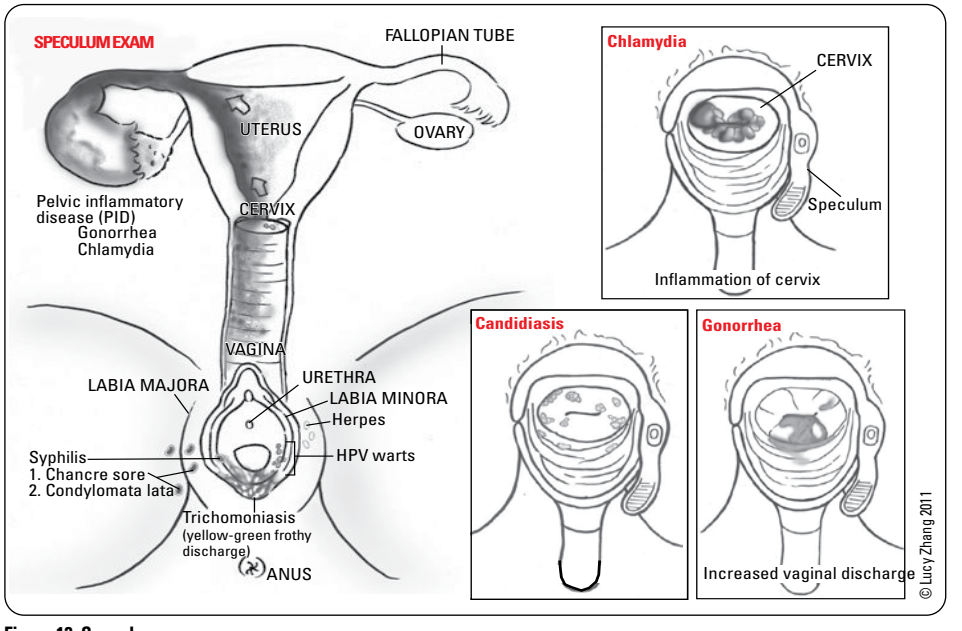

**Figure 13. Speculum exam**

**CDC Notifiable Diseases**
- Chancroid
- Chlamydia
- Gonorrhea
- Hepatitis A, B, C
- HIV
- Syphilis

**Risk Factors for STIs**
- History of previous STI
- Contact with infected person
- Sexually active individual <25 yr
- Multiple partners
- New partner in last 3 mo
- Lack of barrier protection use
- Street involvement (homelessness, drug use)

## TRICHOMONIASIS
- see *Infectious Vulvovaginitis*

## CHLAMYDIA

### Etiology
- Chlamydia trachomatis

### Epidemiology
- most common bacterial STI in Canada
- often associated with *N. gonorrhoeae*

### Clinical Features
- asymptomatic (80% of women)
- muco-purulent endocervical discharge
- urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
- pelvic pain
- postcoital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
- symptomatic sexual partner

### Investigations
- cervical culture or nucleic acid amplification test (can present in pharynx, rectum)
- obligate intracellular parasite: tissue culture is the definitive standard
- urine and self vaginal tests now available, which are equally or more effective than cervical culture

**STI Testing**
- Vaginal swab
  - Tests for bacterial vaginosis, trichomoniasis, candida
- Cervical swab
  - Tests for gonorrhea and chlamydia

### Treatment
- doxycycline 100 mg PO bid for 7 d or azithromycin 1 g PO in a single dose. Doxycycline is contra-indictated in the 2nd and 3rd trimesters of pregnancy
- also treat gonorrhea because of high rate of co-infection
- reportable disease, partners should also be referred for treatment
- test of cure for chlamydia required in pregnancy (cure rates lower in pregnant patients) → retest 3-4 wk after initiation of therapy

### Screening
- high-risk groups
- during pregnancy
- when initiating OCP if sexually active (independent risk factor)

Test of cure for *C. trachomatis* and *N. gonorrhoeae* is not routinely indicated
Repeat testing if symptomatic, if compliance with treatment is uncertain, or if pregnant

### Complications
- PID: low-grade salpingitis and adhesions resulting in tubal obstruction
- infertility
- ectopic pregnancy
- chronic pelvic pain
- Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
- reactive arthritis (male predominance, HLA-B27 associated), conjunctivitis, urethritis
- perinatal infection: conjunctivitis, pneumonia

## GONORRHEA

### Etiology
- Neisseria gonorrhoeae
- symptoms and risk factors same as chlamydia

### Investigations
- Gram stain shows Gram-negative intracellular diplococci
- cervical, rectal, and throat culture (if clinically indicated)

### Treatment
- single dose of ceftriaxone 250 mg IM plus azithromycin 1 g PO
  - if pregnant: above regimen or 2 g spectinomycin IM plus azithromycin 1 g PO (avoid quinolones)
  - also treat chlamydia, due to high rate of co-infection
- treat partners
  - reportable disease
  - screening as with chlamydia

## HUMAN PAPILLOMAVIRUS

### Etiology
- most common viral STI in Canada
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma

### Clinical Features
- latent infection
  - no visible lesions, asymptomatic
  - only detected by DNA hybridization tests
- subclinical infection
  - visible lesion found during colposcopy or on Pap test
- clinical infection
  - visible wart-like lesion without magnification (check pharynx too)
  - hyperkeratotic, verrucous or flat, macular lesions
  - vulvar edema

### Investigations
- cytology
- koilocytosis: nuclear enlargement and atypia with perinuclear halo
- biopsy of lesions at colposcopy
- detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

### Treatment
- patient administered
  - podofilox 0.5% solution or gel bid x 3 d in a row (4 d off) then repeat x 4 wk
  - imiquimod (Aldara®) 5% cream 3x/wk qhs x 16 wk
- provider administered
  - cryotherapy with liquid nitrogen: repeat q1-2wk
  - podophyllin resin in tincture of benzoin: weekly
  - trichloroacetic acid (TCA) (80-90%) or bichloroacetic acid weekly x 4-6 wk; safe in pregnancy
  - surgical removal/laser
  - intralesional interferon

### Prevention
- vaccination: Gardasil®9, Gardasil®, Cervarix® (see Table 28, GY45)
- condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)

## HERPES SIMPLEX VIRUS OF VULVA

### Etiology
- 90% are HSV-2, 10% are HSV-1

### Clinical Features
- may be asymptomatic
- initial symptoms: present 2-21 d after contact
- prodromal symptoms: tingling, burning, pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: less severe, less frequent, and shorter in duration (usually only HSV-2)

### Investigations
- viral culture preferred in patients with ulcer present; however decreased sensitivity as lesions heal
- cytologic smear (Tzanck smear) shows multinucleated giant cells, acidophilic intranuclear inclusion bodies
- HSV DNA PCR
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not available routinely in Canada)

**Genital Warts During Pregnancy**
- Condyloma tend to get larger in pregnancy and should be treated early (consider excision)
- C-section only if obstructing birth canal or risk of extensive bleeding
- Do not use imiquimod, podophyllin, or podofilox

**Human Rights in Health Equity: Cervical Cancer and HPV Vaccines**
Am J Law Med 2009;35:365-87
- While cervical cancer rates have drastically fallen in developed countries due to effective prevention and treatment, socially disadvantaged women within these countries remain disproportionately more likely to develop and die of cervical cancer.
- In most developing countries cervical cancer rates have risen or remained unchanged.
- Must recognize that cervical cancer disparities between race groups, urban and rural residence, and high and low socioeconomic status are attributed to disparate screening and vaccination coverage.
- Programs are implemented without sufficient attention to conditions that render screening less effective or inaccessible to disadvantaged social groups including: lack of information, undervaluing of preventive care, opportunistic delivery in limited health care settings, sexual health stigma, and related [illegible] concerns.

**A 9-Valent HPV Vaccine Against Infection and Intraepithelial Neoplasia in Women**
NEJM 2015;372:711-23
**Purpose**: To determine the efficacy and immunogenicity of the qHPV (types 6, 11, 16, 18) vs. 9vHPV (five additional types 31, 33, 45, 52, 58) vaccines.
**Method**: International randomized, double-blinded phase 2B-3 study of 9vHPV vaccine in 14,215 women between ages of 16-26. Participants were randomized to the 9vHPV vaccine group or the qHPV vaccine group and each received a series of three IM injections (day 1, 2, and 6 mo). Swabs of labial, vulvar, perineal, perianal, endocervical, and ectocervical tissue was obtained and used for HPV DNA testing/Pap smear.
**Results**: Rate of high-grade cervical, vulvar, or vaginal disease was 14.0 per 1000 person-years in both vaccine groups. The rate of high-grade cervical, vulvar, or vaginal disease related to HPV-31, 33, 45, 52, and 58 was 0.1 per 1000 person-years in the 9vHPV group and 1.6 per 1000 person-years in the qHPV group (95% CI = 80.9-99.8). Antibody responses to HPV-6, 11, 16, and 18 were not significantly different between the two vaccine groups although adverse events related to injection sites were more common in the 9vHPV group.
**Conclusions**: The 9vHPV vaccine was non-inferior to qHPV vaccine in preventing infection and disease related to HPV-6, 11, 16, and 18 and also covered additional oncogenic types HPV-31, 33, 45, 52, and 58 in a susceptible population.

### Treatment
- first episode: acyclovir 200 mg PO five times daily x 7-10 d, or famciclovir 250 mg PO tid x 7-10 d or valacyclovir 1 g PO bid x 7-10 d
- recurrent episode: acyclovir 400 mg PO tid x 5 d, valacylovir 1 g PO OD x 5 d or famciclovir 250 mg PO BID x 5 d
- daily suppressive therapy
  - consider for >6 recurrences per yr or recurrence every 2 mo
  - acyclovir 400 mg PO bid or valacyclovir 500 mg PO OD or valacyclovir 1 g PO OD or famciclovir 250 mg PO bid
- severe disease: IV acyclovir 5-10 mg/kg IV q8h x 2-7 d or until clinical improvement observed followed by oral antiviral therapy to complete 10 d of therapy total
- education regarding transmission: avoid sexual contact from onset of prodrome until lesions have cleared, use barrier contraception

## SYPHILIS

### Etiology
- Treponema pallidum

**Epidemiology of Genital Ulcers**

| | |
|---|---|
| HSV | 70-80% |
| 1° Syphilis | 5% |
| Chancroid (*Haemophilus ducreyi*) | <1% |

### Classifications
- primary syphilis
  - 3-4 wk after exposure
  - painless chancre on vulva, vagina, or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection
  - nonspecific symptoms: malaise, anorexia, headache, diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, limbs
  - condylomata lata: anogenital, broad-based, fleshy, grey lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only
- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis, general paresis
  - cardiovascular: aortic aneurysm, dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate, and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths, or neonatal death

### Investigations
- aspiration of ulcer serum or node
- darkfield microscopy (most sensitive and specific diagnostic test for syphilis): look for spirochetes
- non-treponemal screening tests (VDRL, RPR); non-reactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

### Treatment
- reportable disease, partners should be referred for treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
- treatment of latent syphilis of >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units IM q4h x 10-14 d
- screening
  - high-risk groups
  - in pregnancy (see Obstetrics, *Infections During Pregnancy*, OB29)

### Complications
- if untreated, 1/3 will experience late complications

### HIV
- see Infectious Diseases, ID25

# Bartholin Gland Abscess

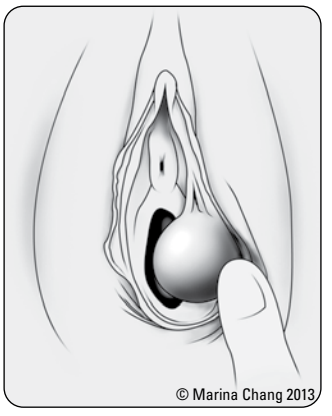

**Figure 14. Bartholin gland abscess**

### Etiology
- often anaerobic and polymicrobial
- *U. urealyticum, N. gonorrhoeae, C. trachomatis, E. coli, P. mirabilis, Streptococcus* spp., *S. aureus* (rare)
- blockage of duct

### Clinical Features
- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

### Treatment
- sitz baths, warm compresses
- antibiotics: cephalexin x 1 wk
- incision and drainage using local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk (or as long as stays in situ)
- marsupialization under general anesthetic: more definitive treatment
- rarely treated by removing gland

# Pelvic Inflammatory Disease

PID accounts for up to 20% of all gynecological hospital admissions

- up to 20% of all gynecology-related hospital admissions
- inflammation of the upper genital tract (above the cervix) including endometrium, fallopian tubes, ovaries, pelvic peritoneum ± contiguous structures

### Etiology
- causative organisms (in order of frequency)
  - *C. trachomatis*
  - *N. gonorrhoeae*
    - gonorrhea and chlamydia often co-exist
  - endogenous flora: anaerobic, aerobic, or both
    - *E. coli, Staphylococcus, Streptococcus, Enterococcus, Bacteroides, Peptostreptococcus, H. influenzae, G. vaginalis*
    - cause of recurrent PID
    - associated with instrumentation
  - *Actinomyces israelii* (Gram-positive, non-acid-fast anaerobe)
    - 1-4% of PID cases associated with IUDs
  - others (TB, Gram-negatives, CMV, *U. urealyticum*, etc.)

### Risk Factors
- age <30 yr
- risk factors as for chlamydia and gonorrhea
- vaginal douching
- IUD (within first 10 d after insertion)
- invasive gynecologic procedures (D&C, endometrial biopsy)

### Clinical Feature
- up to 2/3 asymptomatic: many subtle or mild symptoms
- common: fever >38.3°C, lower abdominal pain and tenderness, abnormal discharge (cervical or vaginal)
- uncommon: N/V, dysuria, AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

**PID Diagnosis**
**Must have**
- Lower abdominal pain

**Plus one of**
- Cervical motion tenderness
- Adnexal tenderness

**Plus one or more of**
- High risk partner
- Temperature >38°C
- Mucopurulent cervical discharge
- Positive culture for *N. gonorrhoeae, C. trachomatis, E. coli,* or other vaginal flora
- Cul-de-sac fluid, pelvic abscess or inflammatory mass on U/S or bimanual
- Leukocytosis
- Elevated ESR or CRP (not commonly used)

### Investigations
- blood work
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine R&M
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - cervical cultures for *N. gonorrhoeae, C. trachomatis*
  - endometrial biopsy will give definitive diagnosis (rarely done)
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy (gold standard)
  - for definitive diagnosis: may miss subtle inflammation of tubes or endometritis

## Treatment

- must treat with polymicrobial coverage

**Table 16. Inpatient and Outpatient Management Options for Pelvic Inflammatory Disease**

| | Inpatient | Outpatient |
|---|---|---|
| **Indications** | Moderate to severe illness<br>Atypical infection<br>Adnexal mass, tubo-ovarian mass, or pelvic abscess<br>Unable to tolerate oral antibiotics or failed oral therapy<br>Immunocompromised<br>Pregnant<br>Adolescent (first episode)<br>Surgical emergency cannot be excluded (e.g. ovarian torsion)<br>PID is secondary to instrumentation | Typical findings<br>Mild to moderate illness<br>Oral antibiotics tolerated<br>Compliance ensured<br>Follow-up within 48-72 h (to ensure symptoms not worsening) |
| **Antibiotic Regimen** | Cefoxitin 2 g IV q6h + doxycycline 100 mg PO/IV q12h or<br>Clindamycin 900 mg IV q8h + gentamycin 2 mg/kg IV/IM loading dose then gentamycin 1.5 mg/kg q8h maintenance dose<br>Continue IV antibiotics for 24 h after symptoms have improved then doxycycline 100 mg PO bid to complete 14 d<br>Percutaneous drainage of abscess under U/S guidance<br>When no response to treatment, laparoscopic drainage<br>If failure, treatment is surgical (salpingectomy, TAH/BSO) | 1st line: ceftriaxone 250 mg IM x 1 + doxycycline 100 mg PO bid x 14 d or cefoxitin 2 g IM x 1 + probenecid 1 g PO + doxycycline 100 mg PO bid ± metronidazole 500 mg PO bid x 14 d<br>2nd line: ofloxacin 400 mg PO bid x14 d or levofloxacin 500 mg PO OD x 14 d ± metronidazole 500 mg PO bid x 14 d<br>Consider removing IUD after a minimum of 24 h of treatment<br>Reportable disease<br>Treat partners<br>Consider re-testing for *C. trachomatis* and *N. gonorrhoeae* 4-6 wk after treatment if documented infection |

## Complications of Untreated PID

- chronic pelvic pain
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID: 13% infertility
  - 2 episodes of PID: 36% infertility
- bacteremia
- septic arthritis, endocarditis

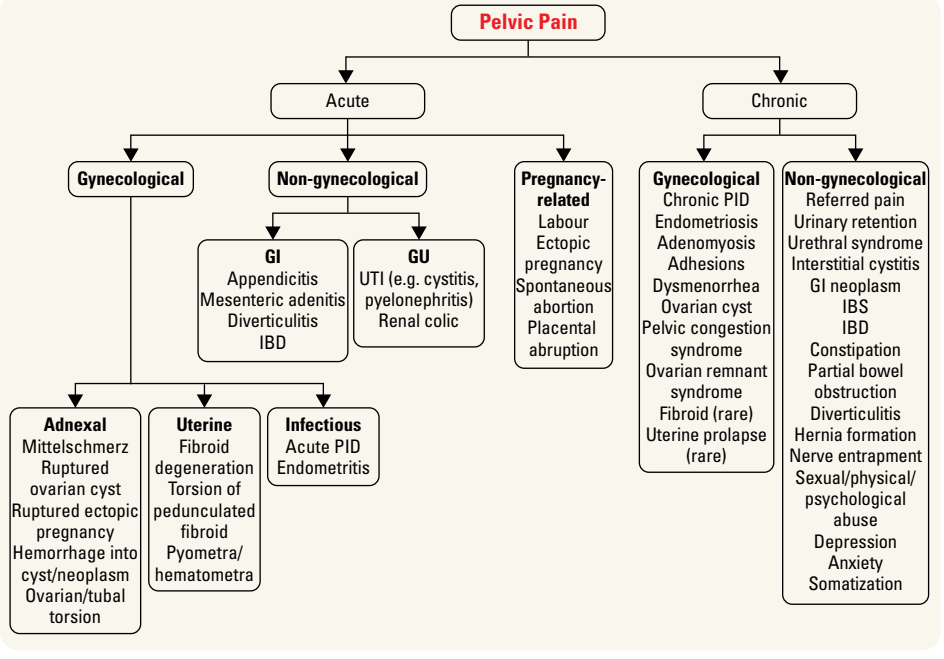

**Figure 15. Approach to pelvic pain**

# Toxic Shock Syndrome

- see Infectious Diseases, ID21

### Risk Factors
- tampon use
- diaphragm, cervical cap, or sponge use (prolonged use, i.e. >24 h)
- wound infections
- post-partum infections
- early recognition and treatment of syndrome is imperative as incorrect diagnosis can be fatal

**Toxic Shock Syndrome**
Multiple organ system failure due to *S. aureus* exotoxin (rare condition)

### Clinical Feature
- sudden high fever
- sore throat, headache, diarrhea
- erythroderma
- signs of multisystem organ failure
- refractory hypotension
- exfoliation of palmar and plantar surfaces of the hands and feet 1-2 wk after onset of illness

### Treatment
- remove potential sources of infection (foreign objects and wound debris)
- debride necrotic tissues
- adequate hydration
- penicillinase-resistant antibiotics (e.g. cloxacillin)
- steroid use controversial, but, if started within 72 h, may reduce severity of symptoms and duration of fever

# Surgical Infections

### Post-Operative Infections in Gynecological Surgery
- pelvic cellulitis
  - common post hysterectomy, affects vaginal vault
  - erythema, induration, tenderness, discharge involving vaginal cuff
  - treat if fever and leukocytosis with broad-spectrum antibiotics (i.e. clindamycin and gentamicin)
  - drain if excessive purulence or large mass
  - can result in intra-abdominal and pelvic abscess
- see General Surgery, *Post-Operative Fever*, GS7

# Sexual Abuse

- see Family Medicine, FM26, Emergency Medicine, ER27

# Sexuality and Sexual Dysfunction

### SEXUAL RESPONSE
1. desire: energy that allows an individual to initiate or respond to sexual stimulation
2. arousal: physical and emotional stimulation leading to breast and genital vasodilation and clitoral engorgement
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 min

### SEXUAL DYSFUNCTION

### Etiology
- psychological or emotional: depression, abuse
- hormonal: menopause
- neurologic dysfunction: spinal cord injury
- vascular insufficiency: DM
- drug side effects: β-blockers
- trauma: episiotomy

### Classification
- lack of desire (60-70% of women)
- lack of arousal
- anorgasmia (5-10%)
  - primary anorgasmia: never before achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but now unable to

- dyspareunia (3-6%): painful intercourse, superficial or deep
  - vaginismus (15%)
  - vulvodynia
  - vaginal atrophy
  - vulvar vestibulitis: associated with history of frequent yeast infections
  - PID

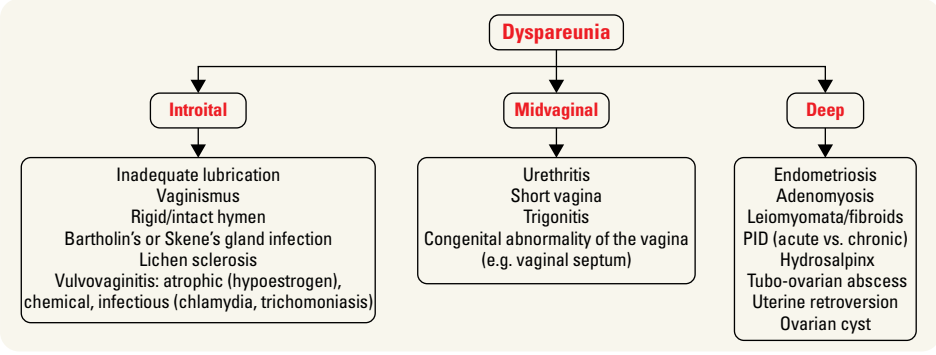

**Figure 16. Approach to dyspareunia**

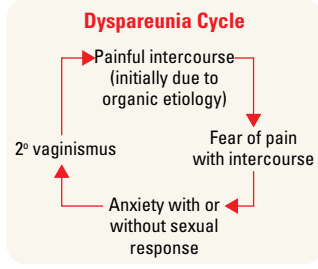

**Figure 17. Dyspareunia cycle**

### Treatment
- lack of desire: assess factors, rule out organic causes, relationship therapy, sensate focus exercises
- anorgasmia: self-exploration/pleasuring, relationship therapy if needed, bridging techniques (different sexual positions, clitoral stimulation during intercourse)
- dyspareunia
  - Kegel and reverse Kegel exercises
  - dilator treatment
  - comfort with self-exam
  - psychotherapy, other behavioural techniques
  - female on top position: allows for control of speed and duration
  - vestibulitis: remove local irritants, change in contraceptive methods, dietary changes (increased citrate, decreased oxalate), and vestibulectomy (rare)
  - vulvodynia: local moisturization, cold compresses, systemic nerve-blocking therapy (amitriptyline, gabapentin) orally or topically, topical anesthetics, estrogen cream
  - pain clinic
  - removal of environmental factors: bubble baths, soaps, perfumes, sanitary pads with plastic lining

**Kegel Exercises**
Regular contraction and relaxation to strengthen pelvic floor muscles

**Reverse Kegel Exercises**
1 s contraction then 5 s of relaxation

# Menopause

- see Family Medicine, FM40

### Definitions
- lack of menses for 1 yr
- types of menopause
  - physiological; average age 51 yr (follicular atresia)
  - primary ovarian insufficiency; before age 40 (autoimmune disorder, infection, Turner's syndrome)
  - iatrogenic (surgical/radiation/chemotherapy)

**Menopause**
Occurrence of last spontaneous menstrual period, resulting from loss of ovarian function (loss of oocyte response to gonadotropins)

**"Being in menopause"**
Lack of menses for 1 yr

**Perimenopause**
Period of time surrounding menopause (2-8 yr preceding + 1 yr after last menses) characterized by fluctuating hormone levels, irregular menstrual cycles, and symptom onset

### Clinical Features
- associated with estrogen deficiency
  - vasomotor instability (tends to dissipate with time)
    - hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, palpitations
  - urogenital atrophy involving vagina, urethra, bladder
    - dyspareunia, pruritus, vaginal dryness, bleeding, post-coital bleeding, urinary frequency, urgency, incontinence
    - inspection may reveal: thinning of tissues, erythema, petechiae, bleeding points, dryness on speculum exam
  - skeletal
    - osteoporosis, joint and muscle pain, back pain
  - skin and soft tissue
    - decreased breast size, skin thinning/loss of elasticity
  - psychological
    - increased anxiety, depression, irritability, fatigue, decreased libido, memory loss

- 85% of women experience hot flashes
- 20-30% seek medical attention
- 10% are unable to work

### Investigations
- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
- FSH level not always predictive due to monthly variation; use absence of menses for 1 yr to diagnose
- decreased levels of estradiol (later)

## Treatment

### Table 17. Treatment of Menopause

| Goal is for individual symptom management | | | | | | |
|---|---|---|---|---|---|---|
| **Vasomotor Instability** | **Vaginal Atrophy** | **Urogenital Health** | **Osteoporosis** | **Decreased Libido** | **CVD*** | **Mood And Memory** |
| HRT (first line)<br>SSRI<br>venlafaxine<br>gabapentin<br>propranaolol<br>clonidine<br>acupuncture | Local estrogen: cream (Premarin®), vaginal suppository (VagiFem®), ring (Estring®), lubricants (Replens®), oral or transdermal hormone replacement therapy, intravaginal laser | Lifestyle changes (weight loss, bladder re-training), local estrogen replacement, surgery | 1000-1500 mg calcium OD, 800-1000 IU vitamin D, weight-bearing exercise, smoking cessation, bisphosphonates (e.g. alendronate), selective estrogen receptor modifiers (SERMs) (e.g.raloxifene [Evista®]), HRT (second-line treatment) | Vaginal lubrications, counselling, androgen-replacement testoterone cream or the oral form (Andriol®) | Manage CVD risk factors | Anti-depressants (first line), HRT (augments effect) |

*CVD (cardiovascular disease)

**Menopause Pathophysiology**

Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)
↓
Less estrogen is produced
↓
Decreased negative feedback on hypothalamic-pituitary-adrenal axis
↓
Increased FSH and LH
↓
Stromal cells continue to produce androgens as a result of increased LH stimulation

**Figure 18. Menopause pathophysiology**

- Osteoporosis is the single most important health hazard associated with menopause
- Cardiovascular disease is the leading cause of death post-menopause

- Increased risk of breast cancer (RR 1.3) is associated with estrogen+progesterone HRT, but not with estrogen-only HRT
- All women taking HRT should have periodic surveillance and counselling regarding its benefits and risks

# Hormone Replacement Therapy

- see Family Medicine, FM40
- primary indication is treatment of menopausal symptoms (vasomotor instability)
- keep doses low (e.g. 0.3 mg Premarin®) and duration of treatment short (<5 yr)

## HRT Components

- estrogen
- oral or transdermal (e.g. patch, gel)
- transdermal preferred for women overall, especially with hypertriglyceridemia or impaired hepatic function, smokers, and women who suffer from headaches associated with oral HRT
- low-dose (preferred dose: 0.3 mg Premarin®/25 µg Estradot® patch, can increase if necessary)
- progestin
- given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

### Table 18. Examples of HRT Regimens

| HRT Regimen | Estrogen Dose | Progestin Dose | Notes |
|---|---|---|---|
| **Unopposed Estrogen** | CEE 0.625 mg PO OD | None | If no intact uterus |
| **Standard-Dose** | CEE 0.625 mg PO OD | MPA 2.5 mg PO OD, or micronized progesterone 100 mg PO OD | Withdrawal bleeding may occur in a spotty, unpredictable manner<br>Usually abates after 6-8 mo due to endometrial atrophy<br>Once patient has become amenorrheic on HRT, significant subsequent bleeding episodes require evaluation (endometrial biopsy) |
| **Standard-Dose Cyclic** | CEE 0.625 mg PO OD | MPA 5-10 mg PO days 1-14 only, or micronized progesterone 200 mg PO OD days 1-14 only | Bleeding occurs monthly after day 14 of progestin (can continue for years)<br>PMS-like symptoms (breast tenderness, fluid retention, headache, nausea) are more prominent with cyclic HRT |
| **Pulsatile** | CEE 0.625 mg PO OD | MPA low-dose | 3 d on, 3 d off |
| **Transdermal** | Estroderm®-Estradiol 0.05 mg/d or 0.1 mg/d<br>Estalis®-Estradiol 140 µg/d or 250 µg/d | Estroderm®-MPA 2.5 mg PO OD<br>Estalis®-NEA 50 µg/d | Use patch twice weekly<br>Can use oral progestins (Estroderm®)<br>Combined patches available (Estalis®) |
| **Topical** | Estrace® 2-4 g/d x 1-2 wk, 1 g/d maintenance<br>Premarin® 0.5-2 g/d for 21 d then off 7 d for vaginal atrophy, 0.5 g/d for 21 d then off 7 d or twice/wk for dyspareunia<br>Estragyn® 2-4 g/d | Crinone® 4% or 8% (45 or 90 mg applicator) | If simultaneously taking oral estrogen tablet, may need to adjust dosing<br>If intact uterus, also take progesterone |

CEE = conjugated equine estrogen (e.g. Premarin®); MPA = medroxyprogesterone acetate (e.g. Provera®); NEA = norethindrone acetate
Consider lower dose regimens, PREMPRO® 0.45/1.5 (Premarin® 0.45 mg and Provera® 1.5 mg); Estrace® (topical 17β-estradiol) = 0.1 mg active ingredient/g; Premarin® (topical CEE) = 0.625 mg active ingredient/g; Estragyn® (topical estrone) = 1 mg active ingredient/g

## Side Effects of HRT

- abnormal uterine bleeding
- mastodynia: breast tenderness and swelling
- edema, bloating, heartburn, nausea
- mood changes (progesterone)
- can be worse in progesterone phase of combined therapy

## Contraindications to HRT

- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - history of breast cancer
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease
- relative
  - pre-existing uncontrolled HTN
  - uterine fibroids and endometriosis
  - familial hyperlipidemias
  - migraine headaches
  - family history of estrogen-dependent cancer
  - chronic thrombophlebitis
  - DM (with vascular disease)
  - gallbladder disease, hypertriglyceridemia, impaired liver function (consider transdermal estrogen)
  - fibrocystic disease of the breasts

**Absolute Contraindications to HRT**

**ABCD**
**A**cute liver disease
Undiagnosed vaginal **B**leeding
**C**ancer (breast/uterine), **C**ardiovascular disease
**D**VT (thromboembolic disease)

## WOMEN'S HEALTH INITIATIVE (launched in 1991)

- two non-randomized studies investigating health risks and benefits of HRT in healthy postmenopausal women 50-79 yr old
  - continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg OD) in 16,608 women with an intact uterus
  - estrogen-alone (CEE 0.625 mg) in 10,739 women with a previous hysterectomy
- both arms of the trial were stopped early because of evidence of increased risk of breast cancer, stroke, PE, and CHD in the combined HRT arm, and increased risk of stroke with no CHD benefits in the estrogen-alone arm
- the apparent increase in CHD was in disagreement with results of previous observational trial
- results of the WHI study have since been challenged and revision of how CHD was diagnosed led to loss of statistical significance of the results
- benefits and risks reported as number of cases per 10,000 women each year

**Table 19. HRT Benefits vs. Risks**

| Benefits | Risks |
|---|---|
| **Vasomotor Symptoms**: less frequent and severe with use of either combined or estrogen alone HRT | **Stroke**: 8 additional cases with combined HRT and 12 additional cases for estrogen alone (WHI) |
| **Osteoporosis**: 5 fewer cases of hip fractures and 47 fewer cases of all fractures with combined HRT; 6 fewer cases of hip fractures with estrogen alone | **DVT/PE**: 18 additional cases with combined HRT and 9 additional cases for estrogen-alone (WHI) |
| **Colon Cancer**: 6 fewer cases with combined HRT (WHI); one additional case with estrogen alone | **CHD**: 7 additional MIs with combined HRT (WHI); secondary analysis suggests greater absolute risk for women aged >70 yr and for women who start HRT >10 yr post-menopause |
| | **Breast Cancer**: 8 additional cases with combined HRT (WHI); risk only increased after >5 yr of combined HRT use; no increased risk for estrogen alone |
| | **Dementia and Mild Cognitive Impairment**: 50% greater risk of developing dementia in women taking estrogen alone after age 65; risk is greater for women taking combined HRT; risk of developing dementia was reduced for women taking HRT before age 65 |

**Long-Term Hormone Therapy for Perimenopausal and Postmenopausal Women**
Cochrane DB Syst Rev 2012;7:CD004143
**Purpose**: To determine the effect of long-term HRT on mortality, cardiovascular outcomes, cancer, gallbladder disease, fractures, cognition, and QOL in perimenopausal and postmenopausal women, during HRT use, and after cessation of HRT.
**Results**: 23 studies with 42,380 women included. 70% of the data from the WHI (1998) and HERS (1998). None of the studies focused on perimenopausal women. Combined continuous HRT: increased risk of coronary event after 1 yr (absolute risk 18/1000, 95% CI 3-7), venous thromboembolism after 1 yr (AR 7/1000, 95% CI 4-11), stroke after 3 yr (AR 18/1000, 95% CI 14-23), breast cancer after 5.6 yr (AR 23/1000, 95% CI 19-29), gallbladder disease after 5.6 yr (AR 27/1000, 95% CI 21-34), and death from lung cancer after 5.6 yr use (AR 9/1000, 95% CI 6-13). Estrogen only HRT: increased risk of venous thromboembolism after 1-2 yr use (AR 5/1000, 95% CI 2-10; after 7 yr AR 21/1000, 95% CI 16-28), stroke after 7 yr (AR 32/1000, 95% CI 25-40), and gallbladder disease after 7 yr use (AR 45/1000, 95% CI 36-57) and did not significantly affect the risk of breast cancer. Women >65 yr of age taking combined HRT had a statistically significant increase in the incidence of dementia after 4 yr use (AR 18/1000, 95% CI 11-30). Women taking HRT had a decreased risk of fractures with combined HRT after 5.6 yr (AR 86/1000, 95% CI 79-84) and 7.1 yr of estrogen only HRT (AR 102/1000, 95% CI 91-112).
**Conclusions**: HRT is not indicated for primary or secondary prevention of cardiovascular disease or dementia. Although HRT is considered effective for the prevention of postmenopausal osteoporosis, it is generally recommended as an option only for women at significant risk, for whom non-estrogen therapies are unsuitable.

# Urogynecology

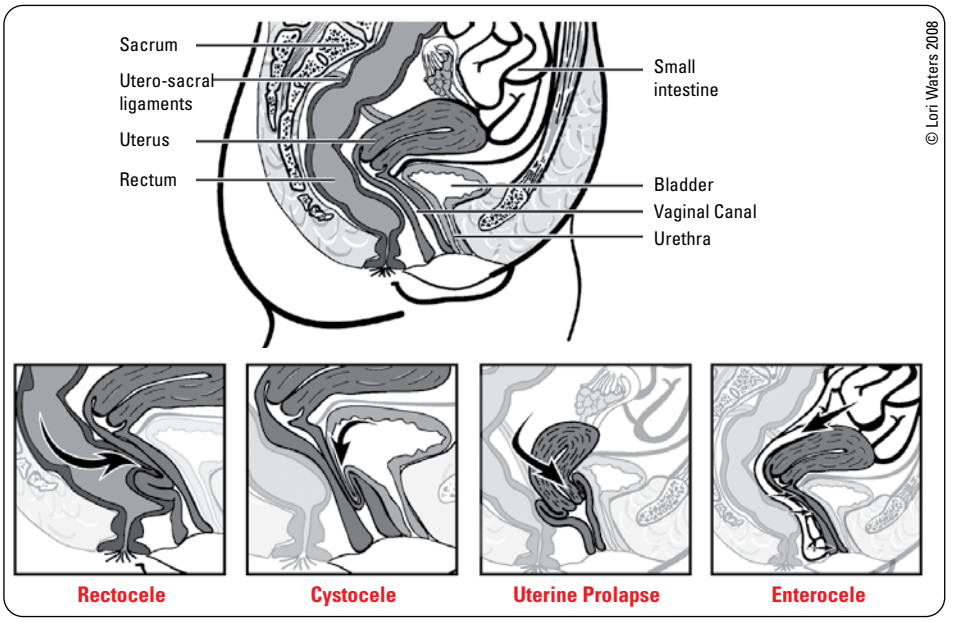

**Figure 19. Pelvic anatomy**

## Prolapse

### Etiology

- relaxation, weakness, or defect in the cardinal and uterosacral ligaments which normally maintain the uterus in an anteflexed position and prevent it from descending through the urogenital diaphragm (i.e. levator ani muscles)
- related to:
  - vaginal childbirth
  - aging
  - decreased estrogen (post-menopause)
  - following pelvic surgery
  - increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  - congenital (rarely)
  - ethnicity (Caucasian women > Asian or African women)
  - collagen disorders

### GENERAL CONSERVATIVE TREATMENT

(for pelvic relaxation/prolapse and urinary incontinence)

- Kegel exercises
- local vaginal estrogen therapy
- vaginal pessary (intravaginal suspension disc)

**Grading of Pelvic Organ Prolapse**

- 0 = no descent during straining
- 1 = distal portion of prolapse >1 cm above level of hymen
- 2 = distal portion of prolapse ≤1 cm above or below level of hymen
- 3 = distal portion of prolapse >1 cm below level of hymen but without complete vaginal eversion
- 4 = complete eversion of total length of lower genital tract
- Procidentia: failure of genital supports and complete protrusion of uterus through the vagina

**Pelvic Relaxation/Prolapse**

Protrusion of pelvic organs into or out of the vagina

**Table 20. Pelvic Prolapse**

| Type | Clinical Features | Treatment |
|---|---|---|
| **Cystocele** (protrusion of bladder into the anterior vaginal wall) | Frequency, urgency, nocturia<br>Stress incontinence<br>Incomplete bladder emptying ± associated increased incidence of UTIs (may lead to renal impairment) | See above<br>Anterior colporrhaphy ("anterior repair")<br>Consider additional/alternative surgical procedure if documented urinary stress incontinence |
| **Enterocele** (prolapse of small bowel in upper posterior vaginal wall) | | Similar to hernia repair<br>Contents reduced, neck of peritoneal sac ligated, uterosacral ligaments, and levator ani muscles approximated |
| **Rectocele** (protrusion of rectum into posterior vaginal wall) | Straining/digitation to evacuate stool<br>Constipation | See above<br>Also laxatives and stool softeners<br>Posterior colporrhaphy ("posterior repair"), plication of endopelvic fascia and perineal muscles approximated in midline to support rectum and perineum (can result in dyspareunia) |
| **Uterine Prolapse** (protrusion of cervix and uterus into vagina) | Groin/back pain (stretching of uterosacral ligaments)<br>Feeling of heaviness/pressure in the pelvis<br>Worse with standing, lifting<br>Worse at the end of the day<br>Relieved by lying down<br>Ulceration/bleeding (particularly if hypoestrogenic)<br>± urinary incontinence | See above<br>Vaginal hysterectomy ± surgical prevention of vault prolapse<br>Consider additional surgical procedures if urinary incontinence, cystocele, rectocele, and/or enterocele are present |
| **Vault Prolapse** (protrusion of apex of vaginal vault into vagina, post-hysterectomy) | | See above<br>Sacralcolpopexy (vaginal vault suspension), sacrospinous fixation, or uterosacral ligament suspension |

The only **true** hernia of the pelvis is an ENTEROCELE because peritoneum herniates with the small bowel

# Urinary Incontinence

• see Urology, U6

## STRESS INCONTINENCE

### Definition
• involuntary loss of urine with increased intra-abdominal pressure (cough, laugh, sneeze, walk, run)

## RISK FACTORS FOR STRESS INCONTINENCE IN WOMEN
• age
• obesity
• parity
• vaginal delivery
• pelvic prolapse
• pelvic surgery
• hypoestrogenic state (post-menopause)
• smoking
• neurological/pulmonary disease

### Treatment
• see *Prolapse*, GY36
• surgical
  ▪ tension-free vaginal tape (TVT), tension-free obturator tape (TOT), prosthetic/fascial slings or retropubic bladder suspension (Burch or Marshall-Marchetti-Krantz procedures)

## URGE INCONTINENCE

### Definition
• urine loss associated with an abrupt, sudden urge to void
• "overactive bladder"
• diagnosed based on symptoms

**Urge Incontinence**
Urine loss associated with an abrupt, sudden urge to void

### Etiology
• idiopathic (90%)
• detrusor muscle overactivity ("detrusor instability")

### Associated Symptoms
• frequency, urgency, nocturia, leakage

**Rule Out Neurological Causes of Urge Incontinence**
• MS
• Herniated disc
• DM

### Treatment
• behaviour modification (reduce caffeine/liquid, smoking cessation, regular voiding schedule)
• Kegel exercises
• medications
  ▪ anticholinergics: oxybutinin (Ditropan®), tolterodine (Detrol®), solifenacin (VESIcare®)
  ▪ tricyclic antidepressants: imipramine

# Gynecological Oncology

## Pelvic Mass

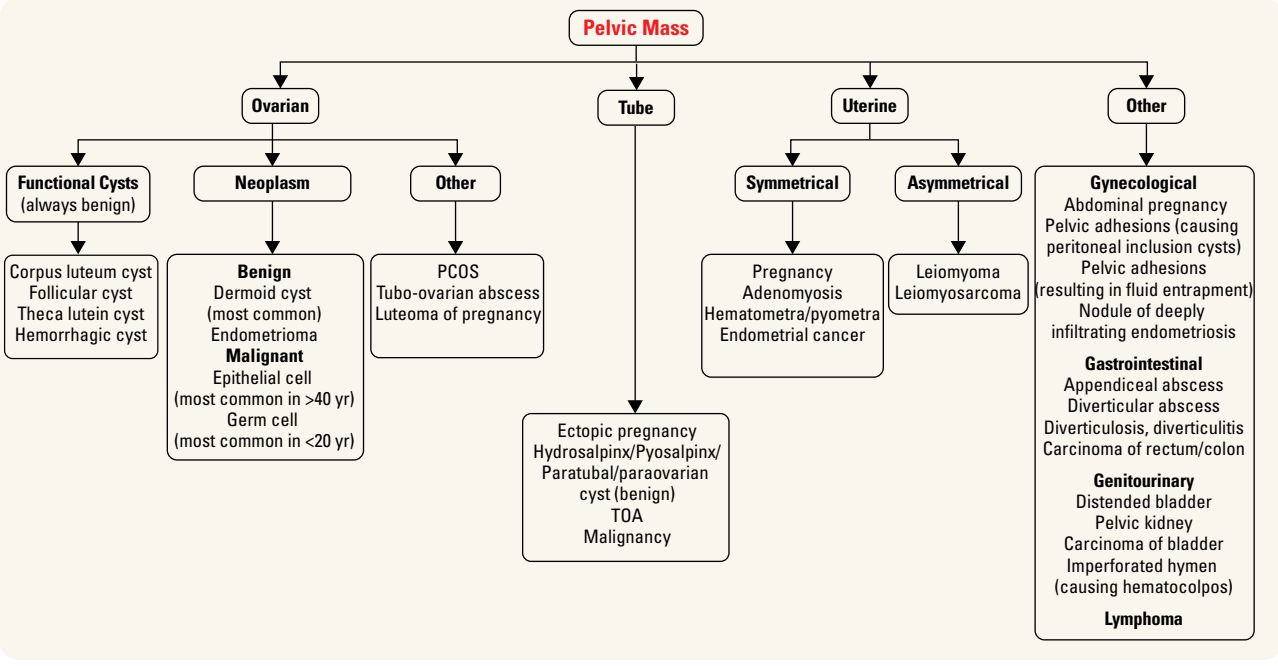

**Figure 20. Differential diagnosis of pelvic mass**

## Uterus

### ENDOMETRIAL CARCINOMA

#### Epidemiology

- most common gynecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of women develop endometrial carcinoma during lifetime
- mean age is 60 yr
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5 yr survival for stage I disease
- 70-80% 5 yr survival for all stages

**Table 21. Features of Type I and Type II Endometrial Cancer**

| | Type I | Type II |
|---|---|---|
| **Description** (Both types related to estrogen, but Type II to a lesser degree) | Characterized as estrogen-related (i.e. excess/unopposed estrogen):<br>Endometrioid<br>Includes well-differentiated endometrioid adenocarcinoma | Characterized as non-estrogen related:<br>Non-endometrioid<br>Includes serous, clear cell, grade 4 endometrioid and undifferentiated carcinomas, as well as carcinosarcoma<br>More aggressive histologic subtypes; prognosis typically worse than type I, with a poorer 5 yr survival |
| **Risk Factors** (Increasing age and family history are risk factors for both types) | PCOS<br>Diabetes mellitus<br>Unbalanced HRT (balanced HRT is protective)<br>Nulliparity<br>Late menopause (>55 yr), early menarche<br>Estrogen-producing ovarian tumours (e.g. granulosa cell tumours)<br>HNPCC (hereditary non-polyposis colorectal cancer)/Lynch II syndrome<br>Tamoxifen | Parous women<br>Increasing age of menarche and number of children not significantly associated with reduced risk in clear-cell endometrial carcinoma<br>Has been associated with p53 mutations |
| **Clinical Features** | ~80% of cases<br>Postmenopausal bleeding in majority<br>Abnormal uterine bleeding in majority of affected pre-menopausal women (menorrhagia, intermenstrual bleeding) | ~15% of cases<br>Post-menstrual bleeding<br>Abnormal uterine bleeding |

**Incidence of Malignant Gynecological Lesions in North America**
endometrium > ovary > cervix > vulva > vagina > fallopian tube

**Risk Factors for Endometrial Cancer**

**COLD NUT**
**C**ancer (ovarian, breast, colon)
**O**besity
**L**ate menopause
**D**iabetes mellitus
**N**ulliparity
**U**nopposed estrogen: PCOS, anovulation, HRT
**T**amoxifen: chronic use

Postmenopausal bleeding = endometrial cancer until proven otherwise (95% present with vaginal bleeding)

An endometrial thickness of 5 mm or more is considered abnormal in a postmenopausal woman with vaginal bleeding

## Screening
- no known benefit for mass screening
- annual endometrial sampling starting at age 30-35 only for women at high risk (HNPCC [Hereditary Non-Polyposis Colorectal Cancer]/ Lynch II syndrome)
- routine pelvic ultrasound should not be used as screening test (high false positives)

## Investigations
- endometrial sampling
  - office endometrial biopsy
  - D&C ± hysteroscopy
- ± pelvic ultrasound (in women where adequate endometrial sampling not feasible without invasive methods)
  - not acceptable as alternative to pelvic exam or endometrial sampling to rule out cancer

**Table 22. FIGO Staging of Endometrial Cancer (2009)**

| Stage | Description | Stage | Description |
|---|---|---|---|
| **I** | Confined to corpus uteri including endocervical glandular involvement | **IIIC** | Metastasis to pelvic ± para-aortic LNs |
| **IA** | No or less than half myometrial invasion | **IIIC1** | Positive pelvic LN |
| **IB** | Invades through ≥½ of myometrium | **IIIC2** | Positive para-aortic LN ± positive pelvic LNs |
| II | Tumour invades cervical stroma, but does not extend beyond uterus* | IV | Invasion of bladder ± bowel mucosa ± distant metastases (note: omental disease is stage IV) |
| III | Tumour involving serosa, adnexa, vagina, or parametrium | **IVA** | Invasion of bladder ± bowel mucosa |
| **IIIA** | Invasion of serosa ± adnexae | **IVB** | Distant mets, including intra-abdominal and intraperitoneal mets ± inguinal LNs |
| **IIIB** | Vaginal ± parametrial involvement | | |

FIGO: International Federation of Gynecology and Obstetrics *Note: endocervical glandular involvement is now considered as Stage I (previously Stage II)

## Treatment
- surgical: hysterectomy/bilateral salpingo-oophorectomy (BSO) and pelvic washings ± pelvic and para-aortic node dissection ± omentectomy
  - goals: diagnosis, staging, treatment, defining optimal adjuvant treatment
  - laparoscopic approach associated with improved quality of life (optimal for most patients)
- adjuvant radiotherapy (for improved local control in patients at risk for local recurrence) and adjuvant chemotherapy (in patients at risk for distant recurrence or with metastatic disease): based on presence of poor prognostic factors in definitive pathology
- chemotherapy: often used for recurrent disease (if high grade or aggressive histology)
- hormonal therapy: progestins can be used for recurrent disease (especially if low-grade)

**Prognostic Factors**
Most important is FIGO stage
Other Prognostic Factors:
- Age
- Grade
- Histologic subtype
- Depth of myometrial invasion
- Presence of lymphovascular space involvement (LVSI)

**Complications of Therapy**

**Surgical Complications**
- Surgical site infection
- Lymphedema

**Radiation Complications**
- Radiation fibrosis
- Cystitis
- Proctois

**Uterine Sarcoma – Symptoms**
**BAD-P**
**B**leeding
**A**bdominal distention
Foul-smelling vaginal **D**ischarge
**P**elvic pressure

A rapidly enlarging uterus, especially in a postmenopausal woman, should prompt consideration of leiomyosarcoma. Nevertheless, all postmenopausal patients with an enlarging uterus should have an endometrial biopsy

## UTERINE SARCOMA
- rare; 3-9% of all uterine malignancies
- arise from stromal components (endometrial stroma, mesenchymal or myometrial tissues)
- behave more aggressively and are associated with worse prognosis than endometrial carcinoma; 5 yr survival is 35%
- vaginal bleeding is most common presenting symptom

**Table 23. Summary of Uterine Sarcoma Subtypes and Features**

| Type | Epidemiology | Features | Diagnosis | Treatment |
|---|---|---|---|---|
| **PURE TYPE** | | | | |
| **1. Leiomyosarcoma** | Most common type of uterine sarcoma<br>Average age of presentation is 55 yr, but may present in pre-menopausal women<br>Often coexists with benign leiomyomata (fibroids) | Histologic distinction from leiomyoma<br>1. Increased mitotic count (>10 mitoses/10 high-power fields)<br>2. Tumour necrosis<br>3. Cellular atypia<br>Rapidly enlarging fibroids in a pre-menopausal woman<br>Enlarging fibroids in a postmenopausal woman | Often post-operatively after uterus removed for presumed fibroids<br>Stage using FIGO 2009 staging for leiomyosarcomas and ECC | Hysterectomy/BSO usually<br>No routine pelvic lymphadenectomy<br>Chemotherapy is used in cases of metastatic disease<br>Radiation therapy does not improve local control or survival<br>Poor outcomes overall, even for early-stage disease |
| **2. Endometrial Stromal Sarcoma (ESS)** | Usually presents in perimenopausal or postmenopausal women with abnormal uterine bleeding | Abnormal uterine bleeding<br>Good prognosis | Diagnosed by histology of endometrial biopsy or D&C<br>Stage using FIGO 2009 staging for leiomyosarcomas and ECC | Hysterectomy & BSO (remove ovaries as ovarian hormones may stimulate growth)<br>No routine pelvic lymphadenectomy<br>Adjuvant therapy based on stage and histologic features (hormones and/or radiation)<br>Hormonal therapy (progestins) may be used for metastatic disease |
| **3. Undifferentiated Sarcoma** | Rare; less common than leiomyosarcoma, endometrial stromal sarcoma | Severe nuclear pleomorphism, high mitotic activity, tumour cell necrosis, and lack smooth muscle or endometrial stromal differentiation<br>Poor prognosis | Often found incidentally post-operatively for abnormal bleeding | Treatment primarily surgical<br>Radiation and/or chemotherapy for advanced diseased or unresectable disease |
| **MIXED TYPE** | | | | |
| **4. Adenosarcoma** | The rarest of the uterine sarcoma<br>Mixed tumour of low malignancy potential | Present with abnormal vaginal bleeding<br>Polypoid mass in uterine cavity | Mixture of benign epithelium with malignant low-grade sarcoma<br>Often found incidentally at time of hysterectomy for PMB<br>Stage using FIGO 2009 staging for adenosarcoma | Treatment is surgical with hysterectomy and BSO |

**Table 24. FIGO Staging of Uterine Sarcoma (2009)**

| Stage | Description | Stage | Description |
|---|---|---|---|
| **I** | **Tumour limited to uterus** | **III** | |
| IA | <5 cm | IIIA | Tumour invades abdominal tissues, one site |
| IB | >5 cm | IIIB | Metastasis to pelvic and/or para-aortic lymph nodes |
| | | IIIC | Tumour invades bladder and/or rectum |
| **II** | **Tumour extends beyond uterus** | **IV** | |
| IIA | To the pelvis, adnexal involvement | IVA | Tumour invades bladder and/or rectum |
| IIB | To extra-uterine pelvic tissue | IVB | Distant metastasis |

# Ovary

## BENIGN OVARIAN TUMOURS

- see Table 25
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
- peritoneal irritation may result from an infarcted tumour (rare)

## MALIGNANT OVARIAN TUMOURS

- see Table 25

### Epidemiology

- lifetime risk 1.4%
- in women >50 yr, more than 50% of ovarian tumours are malignant
- causes more deaths in North America than all other gynecologic malignancies combined
- 4th leading cause of cancer death in women
- 85% epithelial; 15% non-epithelial
- 10-15% of epithelial ovarian cancers are related to hereditary predisposition

### Risk Factors (for epithelial ovarian cancers)

- early menarche and/or late menopause
- personal history of breast, colon, endometrial cancer
- family history of breast, colon, endometrial, ovarian cancer
- Lynch syndrome and BRCA mutations
- use of fertility drugs

### Protective Factors (for epithelial ovarian cancers)

- OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use)
- pregnancy/breastfeeding

### Prophylactic Measures

- salpingectomy (prophylactic)
- BSO (prophylactic hysterectomy or tubal ligation performed for this reason in high-risk women [i.e. BRCA mutation carriers])

### Screening

- no effective method of mass screening
- routine CA-125 level measurements or U/S not recommended
  - high false positive rates
- controversial in high-risk groups: transvaginal U/S and CA-125, starting age 30 (no consensus on interval)
  - familial ovarian cancer (>1 first degree relative affected, BRCA-1 mutation)
  - other cancers (e.g. endometrial, breast, colon)
  - BRCA-1 or BRCA-2 mutation: recommendation is prophylactic bilateral oophorectomy after age 35 or when childbearing is completed

### Clinical Features

- most women with epithelial ovarian cancer present with advanced stage disease as patients often asymptomatic until disseminated (symptoms with early-stage disease are vague and non-specific)
- when present, symptoms may include:
  - abdominal symptoms (nausea, bloating, pain, dyspepsia, anorexia, early satiety)
  - symptoms of mass effect
    - increased abdominal girth (from ascites or tumour itself)
    - urinary urgency and frequency
    - constipation

**Ovaries are like GEMS**
**G**erm-cell
**E**pithelial
**M**etastatic
**S**ex cord stromal

Most (70%) epithelial ovarian cancers present at stage III disease

**Ovarian Tumour Markers**
- Epithelial cell: CA-125
- Stromal
- Granulosa cell: inhibin
- Sertoli-Leydig: androgens
- Germ cell
- Dysgerminoma: LDH
- Yolk sac: AFP
- Choriocarcinoma: β-hCG
- Immature teratoma: none
- Embryonal cell: AFP + β-hCG

Diagnosis of ovarian tumours requires surgical pathology

Any adnexal mass in postmenopausal women should be considered malignant until proven otherwise

**Omental Cake**: a term for ascites plus a fixed upper abdominal and pelvic mass; almost always signifies ovarian cancer

**Malignant Ovarian Tumour Prognosis**
**5 Year Survival**

| | |
|---|---|
| Stage I | 75-95% |
| Stage II | 60-75% |
| Stage III | 23-41% |
| Stage IV | 11% |

**Screening for Ovarian Cancer Updated Evidence Report and Systematic Review for the US Preventive Services Task Force**
JAMA 2018; 319(6):595-606
**Objective**: To systematically review evidence on benefits and harms of ovarian cancer screening among average-risk, asymptomatic women.
**Methods**: Systematic review of RCTs of ovarian cancer screening in average-risk women that reported mortality or quality-of-life outcomes. Interventions included transvaginal ultrasound and/or CA-125 testing. Comparators were usual care or no screening.
**Results**: Four trials (N = 293 587) were included. No trial found a significant difference in ovarian cancer mortality with screening. In 2 trials, screening led to surgery for suspected ovarian cancer in 1% of women without cancer and in 3% for transvaginal ultrasound with or without CA-125 screening, with major complications occurring in 3% to 15% of surgeries. Evidence of psychological harms was found in cases of repeat follow-up scans and tests.
**Conclusions**: Ovarian cancer mortality did not significantly differ between screened women and those with no screening or in usual care.

## Low Malignant Potential (also called "Borderline") Tumours

- a subcategory of epithelial ovarian cancer (~15% of all epithelial ovarian tumours)
- pregnancy, OCP, and breastfeeding are protective factors
- tumour cells with histologically malignant characteristics arise from the ovarian surface, but do not invade ovarian stroma
- able to metastasize, but not commonly
- treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
  - chemotherapy has limited benefit: can be treated with hormonal manipulation (letrozole)
- generally slow growing, excellent prognosis
  - 5 yr survival >99%
  - recurrences tend to occur late, may be associated with low-grade serous carcinoma

### Table 25. Ovarian Tumours

| Type | Description | Presentation | Ultrasound/Cytology | Treatment |
|---|---|---|---|---|
| **FUNCTIONAL TUMOURS (all benign)** | | | | |
| **Follicular Cyst** | Follicle fails to rupture during ovulation | Usually asymptomatic<br>May rupture, bleed, tort, infarct causing pain ± signs of peritoneal irritation | 4-8 cm mass, unilocular, lined with granulosa cells | Symptomatic or suspicious masses warrant surgical exploration<br>Otherwise if <6 cm, wait 6 wk then re-examine as cyst usually regresses with next cycle<br>OCP (ovarian suppression): will prevent development of new cysts<br>Treatment usually laparoscopic (cystectomy vs. oophorectomy, based on fertility choice) |
| **Corpus Luteum Cyst** | Corpus luteum fails to regress after 14 d, becoming cystic or hemorrhagic | More likely to cause pain than follicular cyst<br>May delay onset of next period | Larger (10-15 cm) and firmer than follicular cysts | Same as for follicular cysts |
| **Theca-Lutein Cyst** | Due to atretic follicles stimulated by abnormal β-hCG levels | Associated with molar pregnancy, ovulation induction with clomiphene | | Conservative<br>Cyst will regress as β-hCG levels fall |
| **Endometrioma** | See *Endometriosis*, GY11 | | | |
| **Polycystic Ovaries** | See *Polycystic Ovarian Syndrome*, GY23 | | | |
| **BENIGN GERM-CELL TUMOURS** | | | | |
| **Benign Cystic Teratoma (dermoid)** | Single most common ovarian germ cell neoplasm<br>Elements of all 3 cell lines; contains dermal appendages (sweat and sebaceous glands, hair follicles, teeth) | May rupture, twist, infarct<br>20% bilateral<br>20% occur outside of reproductive yr | Smooth-walled, mobile, unilocular<br>Ultrasound may show calcification which is pathognomonic | Treatment usually laparoscopic cystectomy; may recur |
| **MALIGNANT GERM-CELL TUMOURS** | | | | |
| **General Information** | Rapidly growing, 2-3% of all ovarian cancers | Usually children and young women (<30 yr) | | Surgical resection (often conservative unilateral salpingo-oophorectomy ± nodes) ± chemotherapy |
| **Dysgerminoma** | Produces LDH | 10% bilateral | | When diagnosed at stage IA, no adjuvant treatment is indicated<br>If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure |
| **Immature Teratoma** | No tumour marker identified | Almost always unilateral | | When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated<br>When diagnosed at Grade 2-3, either adjuvant chemotherapy or surgical staging<br>If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure |
| **Yolk Sac Tumour** | Produces AFP | Abdominal pain and pelvic mass | | When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated<br>If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure |
| **Ovarian Choriocarcinoma** | Produces hCG | Precocious puberty and irregular vaginal bleeding | | When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated<br>If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure |
| **EPITHELIAL OVARIAN TUMOURS (malignant or borderline)** | | | | |
| **General Information** | Derived from mesothelial cells lining peritoneal cavity<br>Classified based on histologic type<br>80-85% of all ovarian neoplasms (includes malignant) | | Varies depending on subtype | **Borderline**<br>Cystectomy vs. unilateral salpingo-oophorectomy<br>**Malignant**<br>1. Early stage (stage I): Hysterectomy/BSO/staging (omentectomy, peritoneal biopsies, washings, pelvic and para-aortic lymphadenectomy)<br>2. Advanced stage: Upfront cytoreductive (debulking) followed by adjuvant chemotherapy consisting of IV carboplatic/paclitaxel vs. intraperitoneal chemotherapy (stage III) neoadjuvant chemotherapy with IV carboplatin/paclitaxel, followed by delayed debulking with further adjuvant IV chemotherapy |
| **Serous** | Most common ovarian tumour<br>50% of all ovarian cancers<br>75% of epithelial tumours<br>70% benign | 20-30% bilateral | Lining similar to fallopian tube epithelium<br>Often multilocular<br>Histologically contain Psamomma bodies (calcified concentric concretions) | |

**Table 25. Ovarian Tumours** (continued)

| Type | Description | Presentation | Ultrasound/Cytology | Treatment |
|---|---|---|---|---|
| **EPITHELIAL OVARIAN TUMOURS (malignant or borderline)** | | | | |
| **Mucinous** | 20% of epithelial tumours | Rarely complicated by Pseudomyxoma peritoneii: implants seed abdominal cavity and produce large quantities of mucin | Resembles endocervical epithelium<br>Often multilocular<br>May reach enormous size | Poor response to chemotherapy<br>If mucinous, remove appendix as well to rule out possible source of primary disease |
| **SEX CORD STROMAL OVARIAN TUMOURS** | | | | |
| **General Information** | | | | Surgical resection of tumour<br>Chemotherapy may be used for unresectable metastatic disease |
| **Fibroma/Thecoma (benign)** | From mature fibroblasts in ovarian stroma | Non-functioning<br>Occasionally associated with Meig's syndrome (benign ovarian tumour and ascites and pleural effusion) | Firm, smooth rounded tumour with interlacing fibrocytes | |
| **Granulosa-Theca Cell Tumours (benign or malignant)** | Can be associated with endometrial cancer<br>Inhibin is tumour marker | Estrogen-producing: feminizing effects (precocious puberty, menorrhagia, postmenopausal bleeding) | Histologic hallmark of cancer is small groups of cells known as Call-Exner bodies | |
| **Sertoli-Leydig Cell Tumour (benign or malignant)** | Can measure elevated androgens as tumour markers | Androgen-producing: virilizing effects (hirsutism, deep voice, recession of front hairline) | | |
| **METASTATIC OVARIAN TUMOURS** | | | | |
| **From GI Tract, Breast, Endometrium, Lymphoma** | 4-8% of ovarian malignancies<br>Krukenberg tumour – metastatic ovarian tumour (usually GI tract, commonly stomach or colon, breast) with "signet-ring" cells | | | |

## Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist
  - bimanual examination
    - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
  - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for pre-operative gynecologic oncology referral (see sidebar)
- physical exam findings largely dependent on stage of disease
- blood work: CA-125 for baseline, CBC, liver function tests, electrolytes, creatinine
- radiology
  - transvaginal ultrasound best to visualize ovaries
  - CT abdomen and pelvis to look for metastatic disease
  - bone scan or PET scan not indicated
- try to rule out other primary source if suspected, based on:
  - occult blood per rectum: endoscopy ± barium enema
  - gastric symptoms: gastroscopy ± upper GI series
  - abnormal vaginal bleeding: endometrial biopsy to rule out concurrent endometrial cancer; abnormal cervix: need to biopsy cervix (not Pap smear); breast lesion identified or risk factors present: mammogram

**A Risk of Malignancy Incorporating CA-125, Ultrasound, and Menopausal Status for the Accurate Pre-Operative Diagnosis of Ovarian Cancer**
BJOG 1990;97:922-29
RMI = U x M x CA-125
**Ultrasound Findings (1 pt for each)**
- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions

U = 1 (for U/S scores of 0 or 1)
U = 4 (for U/S scores of 2-5)
**Menopausal Status**
- Postmenopausal: M = 4
- Premenopausal: M = 1

**Absolute Value of CA-125 Serum Level**
- For RMI>200: gynecologic oncology referral is recommended

**Table 26. FIGO Staging for Primary Carcinoma of the Ovary (Surgical Staging) (2014)**

| Stage | Description |
|---|---|
| I | **Growth limited to the ovaries** |
| IA | 1 ovary, no ascites, no tumour on external surface, capsule intact, negative washings |
| IB | 2 ovaries, no ascites, no tumour on external surface, capsule intact |
| IC | 1 or 2 ovaries with any of the following: surgical spill (IC1), capsule ruptured (IC2), tumour on ovarian surface (IC2), or malignant cells in ascites (IC3) |
| **II** | **Growth involving one or both ovaries with pelvic extension or primary peritoneal cancer** |
| IIA | Extension ± implants to uterus/tubes |
| IIB | Extension to other pelvic structures |
| **III** | **Tumour involving one or both ovaries with peritoneal implants outside the pelvis and/or positive retroperitoneal nodes** |
| IIIA | Positive retroperitoneal LNs and/or microscopic metastasis beyond pelvis |
| IIIA1 | Positive retroperitoneal LNs |
| IIIA2 | Microscopic, extrapelvic peritoneal involvement ± positive retroperitoneal LNs |
| IIIB | Macroscopic peritoneal metastasis beyond pelvis ≤2 cm, ± positive retroperitoneal LNs. Includes extension to capsule of liver/spleen |
| IIIC | Same as above but peritoneal metastasis >2 cm |
| **IV** | **Distant metastasis beyond peritoneal cavity** |
| **IVA** | Pleural effusion with positive cytology |
| **IVB** | Hepatic and/or splenic parenchymal metastasis or metastasis to extra-abdominal organs (inguinal LNs and LNs outside of abdominal cavity included) |

FIGO = International Federation of Gynecology and Obstetrics

# Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)
- usually serous epithelial carcinoma
- new evidence shows that some serous ovarian cancers originate in the fallopian tube
- more common in fifth and sixth decade

### Clinical Features
- classic triad present in minority of cases, but very specific
  - watery discharge (most specific): "hydrops tubae profluens"
  - vaginal bleeding or discharge in 50% of patients
  - crampy lower abdominal/pelvic pain
  - most patients present with a pelvic mass (see *Ovarian Tumours*, GY41 for guidelines regarding diagnosis/investigation)

### Treatment
- as for malignant epithelial ovarian tumours

**Effectiveness, Safety, and Cost-Effectiveness of Primary Cytoreductive Surgery**
Cochrane Database Syst *Rev* 2011;(8):CD007565
**Summary**: During primary surgery for stage III or IV epithelial ovarian cancer, all attempts should be made to achieve complete cytoreduction. When this is not achievable, optimal (<1cm) residual disease should be the goal.
**Methods**: Identified 11 retrospective studies consisting of 4735 women using comprehensive search strategy.
**Results:**
1. When suboptimal (margins >1cm) was compared with optimal (<1cm) cytoreduction, the survival estimates were reduced but remained statistically in favour of the lower volume disease group
2. No significant difference in overall survival between suboptimal and optimal cytoreduction
3. Borderline difference in progression-free survival when residual disease >2 cm and <2 cm were compared (p=0.05)

# Cervix

## BENIGN CERVICAL LESIONS
- Nabothian cyst/inclusion cyst: no treatment required
- endocervical polyps: treatment is polypectomy (office procedure)

## MALIGNANT CERVICAL LESIONS

### Epidemiology
- majority are SCC (95%); adenocarcinomas increasing (5%); rare subtypes include small cell, adenosquamous
- 8000 deaths annually in North America
- annual Pap test reduces a woman's chance of dying from cervical cancer from 0.4% to 0.05%
- average age at presentation: 52 yr old

### Etiology
- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from columnar to squamous)
  - a new squamocolumnar junction forms as a result
- the transformation zone (TZ) is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia progresses to carcinoma in situ (CIS), which further progresses to invasion
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

### Risk Factors
- HPV infection
  - see *Sexually Transmitted Infections*, GY26
  - high risk of neoplasia associated with types 16, 18
  - low risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high risk HPV types
- high-risk behaviours (risk factors for HPV infection)
  - multiple partners
  - other STIs (HSV, trichomonas)
  - early age at first intercourse
  - high-risk male partner
- smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
  - immigrant Canadians
  - First Nations Canadians
  - geographically-isolated Canadians
  - sex-trade workers
  - low socioeconomic status Canadians

### Cervical Cancer Screening Guidelines (Pap Test)
- see Family Medicine, FM5

**Causes of Elevated CA-125**
- Age influences reliability of test as a tumour marker
- 50% sensitivity in early-stage ovarian cancer (poor), therefore not good for screening

**Malignant**
- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

**Non-Malignant**
- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure

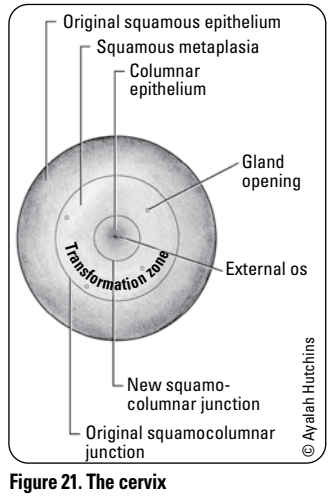

**Figure 21. The cervix**

Cervical cancer is most prevalent in developing countries and, therefore, is the only gynecologic cancer that uses clinical staging; this facilitates consistent international staging with countries that do not have technologies, such as CT and MRI

## Clinical Features

- SCC: exophytic, fungating tumour
- adenocarcinoma: endophytic, with barrel-shaped cervix
- early
  - asymptomatic
  - discharge: initially watery, becoming brown or red
  - postcoital bleeding
- late
  - 80-90% present with bleeding: either postcoital, postmenopausal or irregular bleeding
  - pelvic or back pain (extension of tumour to pelvic walls)
  - bladder/bowel symptoms
- signs
  - friable, raised, reddened, or ulcerated area visible on cervix

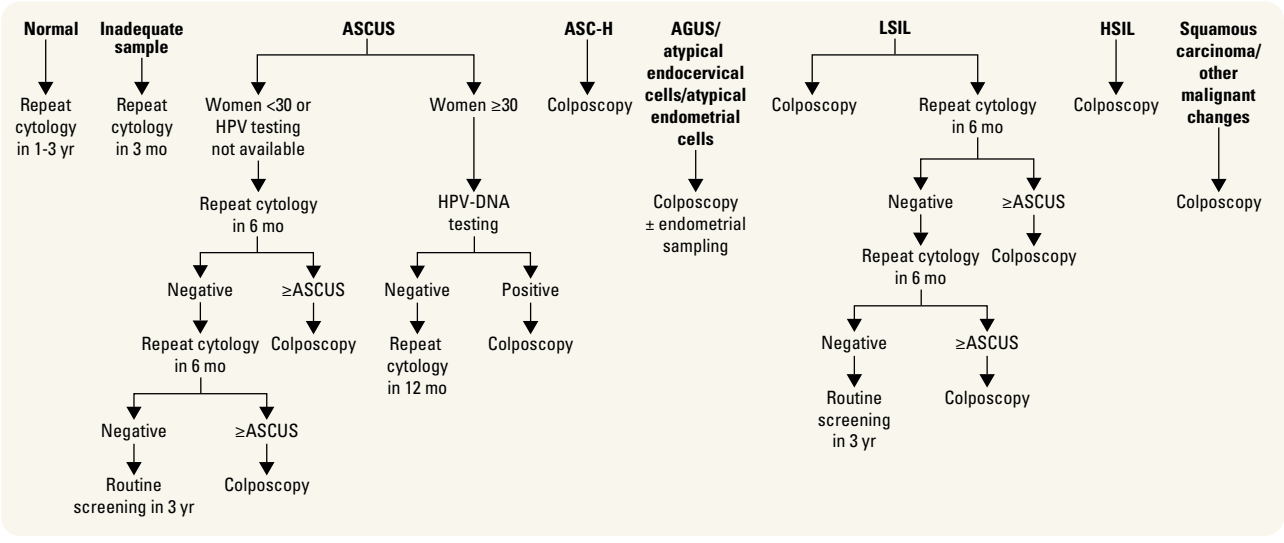

**Figure 22. Decision making chart for Pap test (not applicable for adolescents)**
Adapted from: Ontario Cervical Screening Practice Guidelines. May 2012. Cervical screening guidelines unique to each province

## Diagnosis

- colposcopy is a clinical procedure that facilitates identification and biopsy of suspicious cells
- in colposcopy:
  - apply acetic acid and identify acetowhite lesions, punctation, mosaicism, and abnormal blood vessels to guide cervical biopsy
  - endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
  - diagnostic excision (LEEP) if:
    - unsatisfactory colposcopy (poor visualization/access to transformation zone)
    - discrepancy between cytology, colposcopy, and histological findings
    - positive findings/glandular abnormalities in endocervical curettage
    - suspicious for adenocarcinoma in situ (consider cold-knife conization)
    - recurrence of lesion post-ablation or excision
    - inability to rule out invasive disease, i.e. large lesions (lesions extending into endocervical canal, extending widely on cervix, or onto vaginal epithelium)
- consider cold-knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including examination under anesthesia), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, intravenous pyelogram, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy, results do not influence clinical stage

**The Bethesda Classification System** is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. Cervical intraepithelial neoplasia (CIN) or cervical carcinoma is a histological diagnosis, requiring a tissue sample via biopsy of suspicious lesions seen during colposcopy

With development of hypertension early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

CA-125 is indicated for monitoring response to treatment

**Table 27. FIGO Staging Classification of Cervical Cancer (Clinical Staging) (2018)**

| Stage | Description |
|---|---|
| **I** | **Confined to cervix** |
| IA | Microinvasive (diagnosed only by microscopy) |
| IA1 | Stromal invasion not >3 mm deep, not >7 mm wide |
| IA2 | 3-5 mm deep; not >7 mm wide |
| IB | Clinically visible lesion confined to cervix, or microscopic lesion >IA |
| IB1 | Clinically visible lesion ≤4 mm in greatest dimension |
| IB2 | Clinically visible lesion >4 mm in greatest dimension |
| **II** | **Beyond uterus but not to the pelvic wall or lower 1/3 of vagina** |
| IIA | No obvious parametrial involvement |
| IIA1 | Clinically visible lesion ≤4 mm in greatest dimension |
| IIA2 | Clinically visible lesion >4 mm in greatest dimension |
| IIB | Obvious parametrial involvement |
| **III** | **Extends to pelvic wall, and/or involves lower 1/3 of vagina and/or causes hydronephrosis or non-functioning kidney** |
| IIIA | Involves lower 1/3 vagina but no extension into pelvic side wall |
| IIIB | Extension into pelvic side wall and/or hydronephrosis or non-functioning kidney |
| **IV** | **Carcinoma has extended beyond true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum** |
| IVA | Spread of the growth to adjacent organs (bladder or rectum) |
| IVB | Distant metastases |

## Treatment: Prevention and Management

### Prevention: HPV Vaccine

- two vaccines currently approved (Gardasil®, Cervarix®)

**Table 28. Comparison of Two Vaccines against Human Papillomavirus (HPV)**

| | Gardasil®* | Cervarix® |
|---|---|---|
| **Viral Strains Covered** | 6, 11, 16, 18 | 16, 18 |
| **Route of Administration** | IM | IM |
| **Schedule of Dosing** | 0, 2, 6 mo | 0, 1, 6 mo |
| **Side Effects** | Local: redness, pain, swelling<br>General: headache, low grade fever, GI upset | Local: redness, pain, swelling<br>General: headache, low grade fever, GI upset |
| **Approved Age** | Females age 9-45, males age 9-26 | Females age 10-25 |
| **Contraindications** | Pregnant women and women who are nursing (limited data) | |

*Gardasil-9 also covers types 31, 33, 45, 52, and 58; also used to prevent genital wards

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 d after last dose of vaccination

**Causes of Elevated CA-125**

- Age influences reliability of test as a tumour marker
- 50% sensitivity in early stage ovarian cancer (poor) – therefore not good for screening

**Malignant**

- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

**Non-Malignant**

- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure

**Cervical Cancer Prognosis 5 yr Survival**

| | |
|---|---|
| Stage 0 | 99% |
| Stage I | 75% |
| Stage II | 55% |
| Stage III | 30% |
| Stage IV | 7% |
| Overall | 50-60% |

**Efficacy of Human Papillomavirus (HPV)-16/18 AS04-Adjuvanted Vaccine Against Cervical Infection and Precancer Caused by Oncogenic HPV Types (PATRICIA): Final Analysis of a Double-Blind, Randomized Study in Young Women**

Lancet 2009;374:301-14

**Study**: Phase III double-blind, controlled RCT.

**Patients**: 18,644 women aged 15-25.

**Selected Outcomes**: Development of HPV-16/18 associated CIN II+ was the primary outcome. Secondary to this were persistence of infections with HPV-16, HPV-18, or other oncogenic HPV types.

**Selected Results**: Efficacy against development of HPV-16/18 associated CIN II+ was 98.1% ($p<0.0001$). High levels of cross-protection were observed for persistent infection with HPV-31 and HPV-45 and HPV-31 or HPV-45 associated CIN II+.

**Conclusions**: The HPV-16/18 AS04-adjuvanted vaccine protected against HPV-16/18 associated CIN II+ lesions and lesions associated with HPV-31, HPV-33, and HPV-45.

**Table 29. Management of Abnormal Cervical Histology and Cervical Cancer**

| | Management |
|---|---|
| **CIN I** | Preferred option for biopsy-proven CIN I is observation<br>Repeat assessment and cytology in 12 mo<br>Management according to cytology results<br>If after HSIL or AGC:<br>Cytology and histology should be reviewed<br>If discrepancy remains, excisional biopsy may be considered |
| **CIN II and CIN III** | Women ≥25 yr<br>CIN II or III should be treated<br>Excisional procedures preferred for CIN III<br>Those with positive margins should have follow-up with colposcopy and directed biopsies and/or endocervical curettage<br>Women <25 yr<br>Same treatment for CN II and CN III: observe with colposcopy at 6-mo intervals for up to 24 mo before treatment considered<br>During pregnancy<br>CIN II or III suspected or diagnosed during pregnancy: repeat colposcopy and treatment delayed until 8-12 wk after delivery |
| **Stage IA1 (no LVSI)** | LEEP if future fertility desired (and lesion ≤2 cm)<br>Simple hysterectomy if future fertility is not desired |
| **Stage IA2, IB1** | Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study)<br>If high chance of adjuvant radiation then consider primary chemoradiation as more morbidity occurs from double-modality treatment (surgery and radiation)<br>Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy<br>Advantage is that ovaries can be spared if pre-menopausal<br>For fertility preservation (if tumour <2 cm), may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease<br>Chemoradiation therapy if adverse high-risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins or adverse cervical factors (2 or more): deep stromal invasion, size >4 cm, LVSI |
| **Stages IB2 (>4 cm), II, III, IV** | Primary chemoradiation therapy<br>CT assess extent of disease: evaluate pelvic and para-aortic nodes<br>For positive nodes on PET: primary chemoradiation with extended field RT<br>Hysterectomy generally not suggested following primary treatment with curative intent |

### Abnormal Pap Tests in Pregnancy

- incidence: 1/2200
- Pap test at all initial prenatal visits
  - if abnormal Pap or suspicious lesion, refer to colposcopy
  - if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
  - if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
  - if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
    - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
    - recommendations in T2/T3: delay of therapy until viable fetus and C-sectionfor delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

# Vulva

## BENIGN VULVAR LESIONS

### Non-Neoplastic Disorders of Vulvar Epithelium

- biopsy is necessary to make diagnosis and/or rule out malignancy:

1) Hyperplastic dystrophy (squamous cell hyperplasia)
   - surface thickened and hyperkeratotic
   - pruritus most common symptom
   - typically postmenopausal women
   - treatment: 1% fluorinated corticosteroid ointment bid for 6 wk
2) Lichen sclerosis
   - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
   - pruritus, dyspareunia, burning
   - 'figure of 8' distribution
   - most common in postmenopausal women but can occur at any age
   - treatment: ultrapotent topical steroid 0.05% clobetasol x 2-4 wk then taper down, can consider long-term suppression twice a week
3) Mixed dystrophy (lichen sclerosis with epithelial hyperplasia)
   - hyperkeratotic areas with areas of thin, shiny epithelium
   - treatment: fluorinated corticosteroid ointment

### Tumours
- papillary hidradenoma, nevus, fibroma, hemangioma

## MALIGNANT VULVAR LESIONS

### Epidemiology
- 5% of genital tract malignancies
- 90% SCC; remainder melanomas, basal cell carcinoma, Paget's disease, Bartholin's gland carcinoma
  - Type I disease: HPV-related (50-70%)
    - more likely in younger women
    - 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
  - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
    - usually postmenopausal women

### Risk Factors
- HPV infection
- VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
  - progression to cancer rarely occurs with appropriate management
  - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)
- history of cervical cancer
- cigarette smoking
- immunodeficiency

### Clinical Features
- many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus or lesion most common
- less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
- patterns of spread
  - local
  - groin lymph nodes (usually inguinal, then spreading to pelvic nodes)
  - hematogenous

### Investigations
- ± vulvar biopsy
- always biopsy any suspicious lesion
  - do not remove entire lesion (allows for site identification through sentinel LN injection if malignant)

Any suspicious lesion of the vulva should be biopsied

### Prognosis
- depends on stage: particularly nodal involvement (single most important predictor followed by tumour size)
- lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

### Treatment
- T1 lesions (tumour confined to vulva; no extension to adjacent perineal structures): radical local excision
- T2 lesions (tumour of any size with extension to adjacent perineal structures): modified radical vulvectomy
- T3 lesions (extension to any of: proximal 2/3 of urethra, proximal 2/3 of the vagina, bladder mucosa, rectal mucosa, or fixed to pelvic bone): chemoradiation followed by selective resection of residual primary
- node positive disease: adjuvant chemoradiation or radiation therapy

# Vagina

## BENIGN VAGINAL LESIONS

- inclusion cysts
  - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
  - no treatment required
- endometriosis
  - dark lesions that tend to bleed at time of menses
  - treatment: excision
- Gartner's duct cysts
  - remnants of Wolffian duct, seen along side of cervix
  - treatment: conservative unless symptomatic
- urethral diverticulum
  - can lead to recurrent urethral infection, dyspareunia
  - treatment: surgical correction if symptomatic

## MALIGNANT VAGINAL LESIONS

### Epidemiology

- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are SCC
- more than 50% diagnosed between 70-90 yr old

### Risk Factors

- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

### Investigations

- cytology
  - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are metastatic from one of these sites)
- staging

### Clinical Features

**Table 30. Clinical Features of Malignant Vaginal Lesions**

| Type | Clinical Features |
|---|---|
| **Vaginal Intra-Epithelial Neoplasia (VAIN)** | Grades: analogous to cervical dysplasia |
| **Squamous Cell Carcinoma (SCC)** | Most common site is upper 1/3 of posterior wall of vagina<br>Asymptomatic<br>Painless discharge and bleeding<br>Vaginal discharge (often foul-smelling)<br>Vaginal bleeding especially during/post-coitus<br>Urinary and/or rectal symptom 2° to compression |
| **Adenocarcinoma** | Most are metastatic, usually from cervix, endometrium, ovary, or colon<br>Most primaries are clear-cell adenocarcinomas<br>2 types: non-DES and DES syndrome |

### Treatment

- Stage I
  - radiation therapy: for tumours >2 cm diameter or tumour involvement of the mid- to low-grade vagina
  - surgical excision: radical hysterectomy, upper vaginectomy, and bilateral pelvic lymphadenectomy
- Stage II-IV: chemoradiation

# Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast

## Epidemiology
- 1/1000 pregnancies
- marked geographic variation (as high as 1/125 in Taiwan)
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

## HYDATIDIFORM MOLE (Benign GTD)

### Complete Mole
- most common type of hydatidiform mole
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues or membranes present
- 46XX or 46XY, chromosomes completely of paternal origin (90%)
- 2 sperm fertilize empty egg or 1 sperm with reduplication
- 15-20% risk of progression to malignant sequelae
- risk factors
  - geographic (South East Asia most common)
  - others (maternal age >40 yr, β-carotene deficiency, vitamin A deficiency not proven)
- clinical features often present during apparent pregnancy with abnormal symptoms/findings
  - vaginal bleeding (97%)
  - hyperemesis gravidarum (26%)
  - excessive uterine size for LMP (51%)
  - hyperthyroidism (7%)
  - theca-lutein cysts >6 cm (50%)
  - β-hCG >100,000 IU/L
  - preeclampsia (27%)
  - no fetal heartbeat detected

With development of hypertension early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

### Partial (or Incomplete) Mole
- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXY, XYY, XXX) with chromosome complement from both parents
  - usually related to single ovum fertilized by two sperm
- low risk of progression to malignant sequelae (<4%)
- associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations
- clinical features
  - typically present similar to threatened/spontaneous/missed abortion
  - pathological diagnosis often made after D&C

### Investigations
- quantitative β-hCG levels (tumour marker) abnormally high for gestational age
- U/S findings
  - if complete: no fetus (classic "snow storm" due to swelling of villi)
  - if partial: molar degeneration of placenta ± fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high risk of developing persistent GTN post-evacuation
  - local uterine invasion as high as 31%
  - β-hCG >100,000 IU/L
  - excessive uterine size
  - prominent theca-lutein cysts

### Treatment
- suction D&C with sharp curettage and oxytocin
- Rhogam® if Rh negative
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

### Follow-up
- contraception required to avoid pregnancy during entire follow-up period
- serial β-hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), then monthly for 6-12 mo prior to trying to conceive again
- increase or plateau of β-hCG indicates GTN: patient needs chemotherapy

## GTN (MALIGNANT GTD)

### Invasive Mole or Persistent GTN
- diagnosis made by rising or plateau in β-hCG, development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)

### Choriocarcinoma
- often present with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, abortion, ectopic, or normal pregnancy

### Placental-Site Trophoblastic Tumour
- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

## CLASSIFICATION of GTN
- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of β-hCG
  - negative metastases on staging investigations
- metastatic
  - 4% of patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma, which tends toward early vascular invasion and widespread dissemination
  - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
    - lungs (80%): cough, hemoptysis, CXR lesion(s)
    - vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
    - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
    - liver (10%): elevated LFTs, U/S or CT findings
    - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
  - highly vascular tumour, which is more likely to bleed and result in anemia
  - all have rising or plateau of β-hCG
  - classification of metastatic GTN
    - divided into good prognosis and bad prognosis
    - features of bad prognosis
      - long duration (>4 mo from antecedent pregnancy)
      - high pre-treatment β-hCG titre: >100,000 IU/24 h urine or >40,000 IU/L of blood
      - brain or liver metastases
      - prior chemotherapy
      - metastatic disease following term pregnancy
    - good prognosis characterized by the absence of each of these features

Lungs are the primary site for malignant GTN metastases; when pelvic exam and chest x-ray are negative, metastases are uncommon

### Investigations (for Staging)
- blood work: CBC, electrolytes, creatinine, β-hCG, TSH, LFTs
- imaging: CXR, U/S pelvis only
- if CXR shows lung metastasis then CT abdo/pelvis, MRI brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β-hCG
- ratio of plasma β-hCG:CSF β-hCG <60 indicates metastases

**Table 31. FIGO Staging and Management of Malignant GTN**

| Stage | Findings | Management |
|---|---|---|
| I | Disease confined to uterine corpus | Single agent chemotherapy for low risk disease (WHO score ≤6)<br>1st line: pulsed actinomycin D (Act-D) IV q2wk<br>Alternatives: MTX-based regimen<br>20% of patients need to switch to alternate single-agent regimen due to failure of β-hCG to return to normal<br>Combination chemotherapy (EMA-CO: etoposide, MTX, ACT-D, cyclophosphamide, vincristine) if high risk (WHO score ≥7) or if resistant to single-agent chemotherapy<br>Can consider hysterectomy if fertility not desired or placental-site trophoblastic tumour |
| II | Metastatic disease to genital structures | As above |
| III | Metastatic disease to lungs with or without genital tract involvement | As above |
| IV | Distant metastatic sites including brain, liver, kidney, GI tract | Usually high risk (EMA-CO) with surgical resection of sites of disease<br>Persistence/resistance to chemotherapy<br>Consider radiation for brain mets |

**Table 32. WHO Prognostic Score for GTD (2011)**

| | Score | | | |
|---|---|---|---|---|
| **Prognostic Factor** | **0** | **1** | **2** | **4** |
| **Maternal Age** | >40 | 40 | | |
| **Antecedent Pregnancy** | Mole | Abortion | Term | |
| **Interval (End of Antecedent Pregnancy to Chemotherapy in Months)** | <4 | 4-6 | 7-13 | >13 |
| **HCG IU/1** | <103 | 103-104 | 104-105 | >105 |
| **Number of Metastases** | 0 | 1-4 | 5-8 | >8 |
| **Site of Metastases** | Lung | Spleen, kidney | GI tract | Brain, liver |
| **Largest Tumour Mass** | | 3-5 cm | >5 cm | |
| **Prior Chemotherapy** | | | Single drug | Two drug |

### Follow-up (for GTN)

- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 12 mo
- stage IV
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 24 mo

### GTN Diagnosis

- β-hCG plateau: <10% drop in β-hCG over four values in 3 wk (e.g. days 1, 7, 14, and 21) OR
- β-hCG rise >20% in any two values over two wk or longer (e.g. measure at days 1, 7, 14) OR
- β-hCG persistently elevated >6 mo OR
- metastases on work-up

# Common Medications

**Table 33. Common Medications**

| Drug Name (Brand Name) | Action | Dosing Schedule | Indications | Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I) |
|---|---|---|---|---|
| **acyclovir (Zovirax®)** | Antiviral; inhibits DNA synthesis and viral replication | **First Episode**: 400 mg PO tid x 7-10 d<br>**Recurrence**: 400 mg PO tid x 5 d | Genital herpes | **S/E**: headache, GI upset<br>**D/I**: zidovudine, probenecid |
| **bromocriptine (Parlodel®)** | Dopaminomimetic, agonist at D2R and antagonist at D1R; acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin | **Initial**: 1.25-2.5 mg PO qhs with food<br>Then: increase by 2.5 mg every 2-7 d as needed until optimal therapeutic response<br>**Usual Range**: 1.5-15 mg OD<br><br>For IVF:<br>**Initial**: 1.25 mg/d PO between days 4-6 of follicular phase<br>**Then**: 2.5 mg/d until 3 d after onset menstruation | Galactorrhea + amenorrhea 2° to hyperprolactinemia<br>Prolactin-dependent menstrual disorders and infertility<br>Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas)<br>IVF | **S/E**: N/V, headache, postural hypotension, somnolence<br>**C/I**: uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding<br>**D/I**: domperidone, macrolides, octreotide |
| **clomiphene citrate (Clomid®)** | Increases output of pituitary gonadotropins to induce ovulation | 50 mg OD x 5 d<br>Try 100 mg or 160 mg OD<br>If ineffective 3 courses: adequate trial | Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy | **S/E**: Common: hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz<br>Rare: ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects<br>**C/I**: pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding |
| **clotrimazole (Canesten®)** | Antifungal; disrupt fungal cell membrane | **Tablet**: 100 mg/d intravaginally x 7 d or 200 mg/d x 3 d or 500 mg x 1 dose<br>**Cream** (1 or 2%): 1 applicator intravaginally qhs x 3-7 d<br>**Topical**: apply bid x 7 d | Vulvovaginal candidiasis | **S/E**: vulvar/vaginal burning |
| **danazol (Cyclomen® [CAN]) (Danocrine® [US])** | Synthetic steroid: inhibits pituitary gonadotropin output and ovarian steroid synthesis<br>Has mild androgenic properties | 200-800 mg in 2-3 divided doses<br>Use for 3-6 mo<br>Biannual hepatic U/S required if >6 mo use | Endometriosis<br>1° menorrhagia/DUB | **S/E**: weight gain, acne, mild hirsutism, hepatic dysfunction<br>**C/I**: pregnancy, undiagnosed vaginal bleeding, breastfeeding, severely impaired renal/hepatic/cardiac function, porphyria, genital neoplasia, thromboembolic disease<br>**D/I**: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives |

**Table 33. Common Medications** (continued)

| Drug Name (Brand Name) | Action | Dosing Schedule | Indications | Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I) |
|---|---|---|---|---|
| **doxycycline** | Tetracycline derivative; inhibit protein synthesis | 100 mg PO bid x ≥7 d | Chlamydia, gonococcal infection, syphilis | **S/E**: GI upset, hepatotoxicity<br>**C/I**: pregnancy, severe hepatic dysfunction<br>**D/I**: warfarin, digoxin |
| **fluconazole (Diflucan®)** | Antifungal; disrupt fungal cell membrane | 150 mg PO x 1 dose | Vulvovaginal candidiasis unresponsive to clotrimazole | **S/E**: headache, rash, N/V, abdominal pain, diarrhea<br>**D/I**: terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin |
| **leuprolide (Lupron®)** | Synthetic GnRH analog; induces reversible hypoestrogenic state | 3.75 mg IM q1mo or 11.25 mg IM q3mo<br>Usually ≤6 mo, check bone density if >6 mo<br>Retreatment with Lupron® alone not recommended because of effects on bone density | Endometriosis<br>Leiomyomata<br>DUB<br>Precocious puberty | **S/E**: hot flashes, sweats, headache, vaginitis, reduction in bone density, acne, GI upset<br>**C/I**: pregnancy, undiagnosed vaginal bleeding, breastfeeding |
| **menotropin (Pergonal®)** | Human gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development | 75-150 U of FSH and LH IM OD x 7-12 d, then 10,000 U HCG 1 d after last dose | Infertility | **S/E**: bloating, irritation at injection site, abdominal/pelvic pain, headache, N/V, multiple pregnancy<br>**C/I**: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding |
| **metronidazole (Flagyl®)** | Bactericidal; forms toxic metabolites which damage bacterial DNA | 2 g PO x 1 dose or 500 mg PO bid x 7 d | Bacterial vaginosis, trichomonas vaginitis | **S/E**: headache, dizziness, N/V, diarrhea, disulfiram-like reaction (flushing, tachycardia, N/V)<br>**C/I**: pregnancy (1st trimester)<br>**D/I**: cisapride, warfarin, cimetidine, lithium, alcohol, amiodarone, milk thistle, carbamazepine |
| **oxybutinin (Ditropan®)** | Anticholinergic; relaxes bladder smooth muscle, inhibits involuntary detrusor contraction | 5 or 10 mg/d PO<br>May increase doses by 5 mg weekly to a max of 30 mg/d | Overactive bladder (urge incontinence) | **S/E**: dry mouth/eyes, constipation, palpitations, urinary retention, dizziness, headache<br>**C/I**: glaucoma, GI ileus, severe colitis, obstructive uropathy, use with caution if impaired hepatic/renal function |
| **tolterodine (Detrol®)** | Anticholinergic | 1-2 mg PO bid | Overactive bladder (urge incontinence) | **S/E**: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain, abdominal pain<br>**C/I**: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function |
| **tranexamic acid (Cyklokapron®)** | Anti-fibrinolytic; reversibly inhibits plasminogen activation | 1-1.5 g tid-qid for first 4 d of cycle<br>Max 4 g/d<br>Ophthalmic check if used for several wk | Menorrhagia | **S/E**: N/V, diarrhea, dizziness, rare cases of thrombosis, abdominal pain, MSK pain<br>**C/I**: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age <15 yr |
| **ulipristal acetate (Fibristal®)** | Selective progesterone receptor modulator (SPRM) | 5 mg PO OD for max 3 mo; first tablet taken anytime during first 7 d of menstruation | Leiomyoma (pre-operative) | **S/E**: headache, hot flushes, constipation, vertigo, endometrial thickening<br>**C/I**: pregnancy, undiagnosed vaginal bleeding, any gynecological cancer |
| **urofollitropin (Metrodin®)** | FSH | 75 U/d SC x 7-12 d | Ovulation induction in PCOS | **S/E**: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy<br>**C/I**: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, abnormal uterine bleeding |
| **combined oral contraceptive pill (OCP)** | Ovulatory suppression by inhibiting LH and FSH<br>Decidualization of endometrium<br>Thickening of cervical mucus to prevent sperm penetration | | Contraception<br>Disorders of menstruation | See Table 8-12 |
| **intrauterine device (IUD)**<br>**copper IUD (Nova-T®)**<br>**progesterone-releasing IUD (Mirena®, Jaydess®)** | **Copper IUD**: mild foreign body reaction in endometrium, which is toxic to sperm and alters sperm motility<br>**Progesterone-releasing IUD**: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation | Contraceptive effects last 3 yr (Jaydess®); up to 5 yr (Copper IUD, Mirena®) | Same as above | See Table 8-12 |

# Basics of Hematology

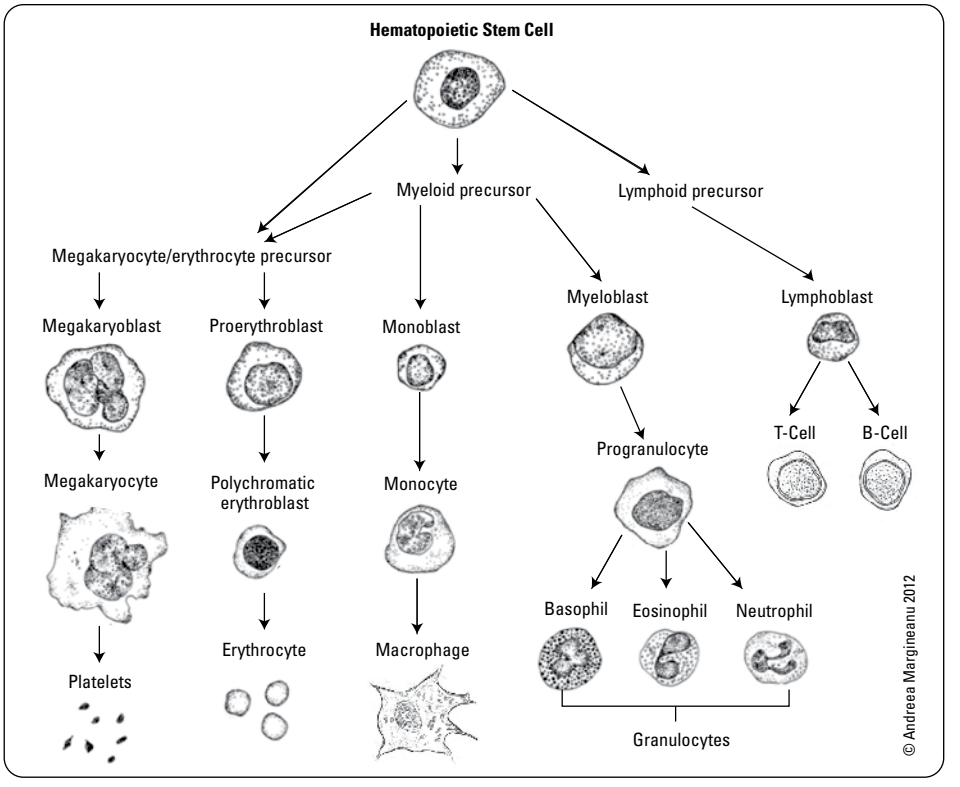

**Figure 1. Hematopoiesis**

**Erythrocyte:** carries oxygen from lungs to peripheral tissues

**Reticulocyte:** immature erythrocyte

**Neutrophil:** granulocyte integral in innate immunity; main cell in acute inflammation

**Eosinophil:** involved in response to parasites (especially helminths) and allergic response

**Basophil:** granulocyte mainly involved in allergy and parasitic infection

**Lymphocyte:** integral cell in adaptive immunity

**Monocyte:** involved in innate immunity; can differentiate into macrophage or dendritic cell

**Platelet:** mediator of primary hemostasis

**Plasma:** liquid component of blood containing water, proteins, coagulation factors, and immunoglobulins

**Serum:** equivalent to plasma minus clotting factors and fibrinogen

- over $10^{11}$ blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies, and cranium
- lifespan of mature cells in blood
  - erythrocytes (90-120 d), neutrophils (~1 d), platelets (7-10 d), lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
  - spleen: part of reticuloendothelial system, sequesters aged RBCs, removes opsonized cells, and site of antibody production
  - thymus: site of T-cell maturation and involutes with age
  - lymph nodes: sites of B and T-cell activation (adaptive immune response)

# Complete Blood Count

**Table 1. Common Terms Found in the CBC**

| Test | Definition | Normal Values* |
|---|---|---|
| **Red Blood Cell (RBC) Count** | The number of RBCs per volume of blood | 4.2-6.9 x $10^6$/mm$^3$ |
| **Hemoglobin (Hb)** | Amount of oxygen-carrying protein in the blood | 130-180 g/L (male)<br>120-160 g/L (female) |
| **Hematocrit (Hct)** | Percentage of a given volume of whole blood occupied by packed RBCs | 45%-62% (male)<br>37%-48% (female) |
| **Mean Corpuscular Volume (MCV)** | Measurement of RBC size | 80-100 μm$^3$ |
| **Mean Corpuscular Hb (MCH)** | Amount of oxygen-carrying Hb inside RBCs | 27-32 pg/cell |
| **Mean Corpuscular Hb Concentration (MCHC)** | Average concentration of Hb inside RBCs | 32%-36% |
| **RBC Distribution Width (RDW)** | Measurement of variance in RBC size | 11.0%-15.0% |
| **White Blood Cell (WBC) Count** | The number of WBCs per volume of blood | 4.3-10.8 x $10^9$/mm$^3$ |
| **WBC Differential** | Neutrophils<br>Lymphocytes<br>Monocytes<br>Eosinophils<br>Basophils | 1.8-7.8 x $10^3$/mm$^3$<br>0.7-4.5 x $10^3$/mm$^3$<br>0.1-1.0 x $10^3$/mm$^3$<br>0.0-0.4 x $10^3$/mm$^3$<br>0.0-0.2 x $10^3$/mm$^3$ |
| **Platelet Count** | The number of platelets per volume of blood | 150-400 x $10^9$/mm$^3$ |
| **Mean Platelet Volume (MPV)** | Measurement of platelet size | 7.2-11.7 fL |
| **Reticulocytes** | Immature RBCs that contain no nucleus but have residual RNA | Normally make up 1% of total RBC count |

*Normal values may vary depending on site and age

To estimate Hb based on the Hct, multiply by 3.3

**Clinical Use of RDW**
To distinguish the etiologies of microcytosis:
- Iron deficiency: increased RDW (anisocytosis) as cells are of varying sizes in iron deficiency
- Thalassemia minor: normal RDW (also expect a high RBC count) as cells are of similar size due to genetic defect in Hb

### Approach to Interpreting a CBC

1. consider values in the context of individual's baseline:
   - up to 5% of population without disease may have values outside "normal" range
   - an individual may display a clinically significant change from their baseline without violating "normal" reference range
2. is one cell line affected or are several?
   - if all lines are low: pancytopenia (see *Pancytopenia*, H8)
   - if RBCs and platelets are low: consider a MAHA/TMA (see *Microangiopathic Hemolytic Anemia/Thrombotic Microangiopathy*, H22)
   - if single cell line affected: see *Common Presenting Problems*, H6

# Blood Film Interpretation

## RED BLOOD CELLS

### Size

- microcytic (MCV <80 μm$^3$), normocytic (MCV = 80-100 μm$^3$), macrocytic (MCV >100 μm$^3$)
- anisocytosis: RBCs with increased variability in size (increased RDW)
  - iron deficiency anemia, hemolytic anemias, myelofibrosis, blood transfusion, and MDS

### Colour

- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
  - iron deficiency anemia, anemia of chronic disease, and sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
  - increased RBC production by bone marrow

### Shape

- poikilocytosis: increased proportion of RBCs of abnormal shape
  - iron deficiency anemia, myelofibrosis, severe $B_{12}$ deficiency, MDS, and burns

## Table 2. Common Erythrocyte Shapes

| Shape | Definition | Associated Conditions |
|---|---|---|
| **Discocyte**  | Biconcave disc | Normal RBC |
| **Spherocyte**  | Spherical RBC (due to loss of membrane) | Hereditary spherocytosis, immune hemolytic anemia |
| **Elliptocyte/Ovalcyte**  | Oval-shaped, elongated RBCs<br>• Elliptocytes: the RBC long axis is ≥2x the length of the short axis<br>• Ovalocytes: the RBC long axis is <2x the length of the short axis | Hereditary elliptocytosis, megaloblastic anemia, myelofibrosis, iron-deficiency, and MDS |
| **Schistocyte (helmet cell, fragment)**  | Fragmented cells (due to traumatic disruption of membrane) | Microangiopathic hemolytic anemia (HUS, aHUS, TTP, DIC, preeclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, and prosthetic heart valve |
| **Sickle Cell**  | Sickle-shaped RBC (due to polymerization of hemoglobin S) | Sickle cell disorders: HbSC, HbSS |
| **Codocyte (target cell)**  | "Bull's eye" on dried film | Liver disease, hemoglobin SC, thalassemia, iron deficiency, and asplenia |
| **Dacrocyte (teardrop cell)**  | Single pointed end, looks like a teardrop | Myelofibrosis, MDS, thalassemia major, megaloblastic anemia, and bone marrow infiltration |
| **Acanthocyte (spur cell)**  | Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids) | Severe liver disease (spur cell anemia), starvation/anorexia, and post-splenectomy |
| **Echinocyte (burr cell)**  | RBC with numerous regularly spaced, small, spiny projections | Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, and storage artifact |
| **Rouleaux Formation**  | Aggregates of RBC resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins) | Pregnancy is most common cause (due to physiological increase in fibrinogen)<br>Inflammatory conditions (due to polyclonal immunoglobulins)<br>Plasma cell dyscrasias (due to monoclonal paraproteinemia, e.g. multiple myeloma, macroglobulinemia)<br>Storage artifact |

DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes, and low platelet count; HUS = hemolytic uremic syndrome; aHUS = atypical HUS; TTP = thrombotic thrombocytopenic purpura
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

## Table 3. RBC Inclusions

| Inclusions | Definition | Associated Conditions |
|---|---|---|
| **Nucleus**  | Present in erythroblasts (immature RBCs) | Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, and MPNs (MF) |
| **Heinz Bodies**  | Denatured and precipitated hemoglobin | G6PD deficiency (post-exposure to oxidant), thalassemia, and unstable hemoglobins |
| **Howell-Jolly Bodies**  | Small nuclear remnant resembling a pyknotic nucleus | Post-splenectomy, hyposplenism (sickle cell disease), neonates, and megaloblastic anemia |
| **Basophilic Stippling**  | Deep blue granulations indicating ribosome aggregation | Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, MDS, and hereditary (pyrimidine 5'nucleotidase deficiency) |
| **Sideroblasts**  | Late erythrocytes in BM with Fe containing granules in the cytoplasm | Hereditary, idiopathic, drugs, EtOH, hypothyroidism (see *Sideroblastic Anemia*, H16), and myelodysplastic syndrome, toxins (lead) |

BM = bone marrow; MF = myelofibrosis; MPN = myeloproliferative neoplasm
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

## WHITE BLOOD CELLS

- lymphocytes
  - comprise 30-40% of WBCs; great variation in "normal" lymphocyte morphology
- neutrophils
  - normally, only mature neutrophils (with 3-4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
  - hypersegmented neutrophil: >5 lobes suggests megaloblastic process ($B_{12}$ or folate deficiency)
  - left shift (increased granulocyte precursors)
    - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, and myeloproliferative neoplasms (CML, MF)
- blasts
  - immature, undifferentiated precursors; associated with acute leukemia, MDS, and G-CSF (growth factor that stimulates neutrophil production) use

**Left Shift**
Refers to an increase in granulocyte precursors in the peripheral smear (myelocytes, metamyelocytes, promyelocytes, blasts). If present, implies increased marrow production of granulocytes (e.g. inflammation, infection, G-CSF administration, CML)
The presence of predominantly blasts in the peripheral smear without further differentiated precursor cells or mature neutrophils, suggests clonal cell disorder (MDS, acute leukemias)
If >20% of the total WBC differential consists of blasts, this is acute leukemia and is a medical emergency

**Table 4. Abnormal White Blood Cells on Film**

| Appearance | Definition | Associated Conditions |
|---|---|---|
| **Smudge Cell**  | Lymphocytes damaged during blood film preparation indicating cell fragility | CLL and other lymphoproliferative disorders |
| **Auer Rod**  | Cytoplasmic inclusions that form long needles in the cytoplasm of myeloblasts | Pathognomonic for acute myeloid leukemia (AML) |
| **Atypical Lymphocyte**  | Pale blue cytoplasm following RBC edges with pink granules | Viruses (particularly EBV) and T-cell large granular lymphocyte leukemia (T-LGL) |

EBV = Epstein-Barr virus; CLL = chronic lymphocytic leukemia
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012 and Danielle Sayeau 2017

## PLATELETS

- small, purple, anuclear cell fragments

# Bone Marrow Aspiration and Biopsy

- sites: posterior iliac crest/spine, sternum (aspiration only)
- analyses: most often done together
  - aspiration: takes a fluid marrow sample for cellular morphology, flow cytometry, cytogenetics, molecular studies, and microbiology (C&S, acid-fast bacilli, and PCR)
    - note: differential diagnosis for a "dry tap": MF, hairy cell leukemia, bone marrow infiltration
  - biopsy: takes a sample of intact bone marrow to assess histology (architecture) and immunohistochemistry
  - only aspirates, not biopsies, can be obtained from the sternal site

### Indications

- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, and solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of unknown origin, suspected mycobacterial, fungal, and parasitic infections, or granulomatous disease
- evaluate unexplained splenomegaly
- confirm normal bone marrow in potential allogeneic hematopoietic cell donor

### Important Considerations

- consult a hematologist prior to conducting a bone marrow biopsy on a patient with an inherited (e.g. hemophilia, vWF disease) or acquired (e.g. DIC, anticoagulant therapy, coagulopathy of liver disease, and severe thrombocytopenia) bleeding diathesis to determine if pro-hemostatic therapy is indicated pre-procedure
- do not perform a bone marrow biopsy if there is evidence of infection over the targeted skin site

# Common Presenting Problems

## Anemia

### Definition

- a decrease in RBC mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
  - adult males: Hb <130 g/L or Hct <41%
  - adult females: Hb <120 g/L or Hct <36% (changes with pregnancy and trimester)

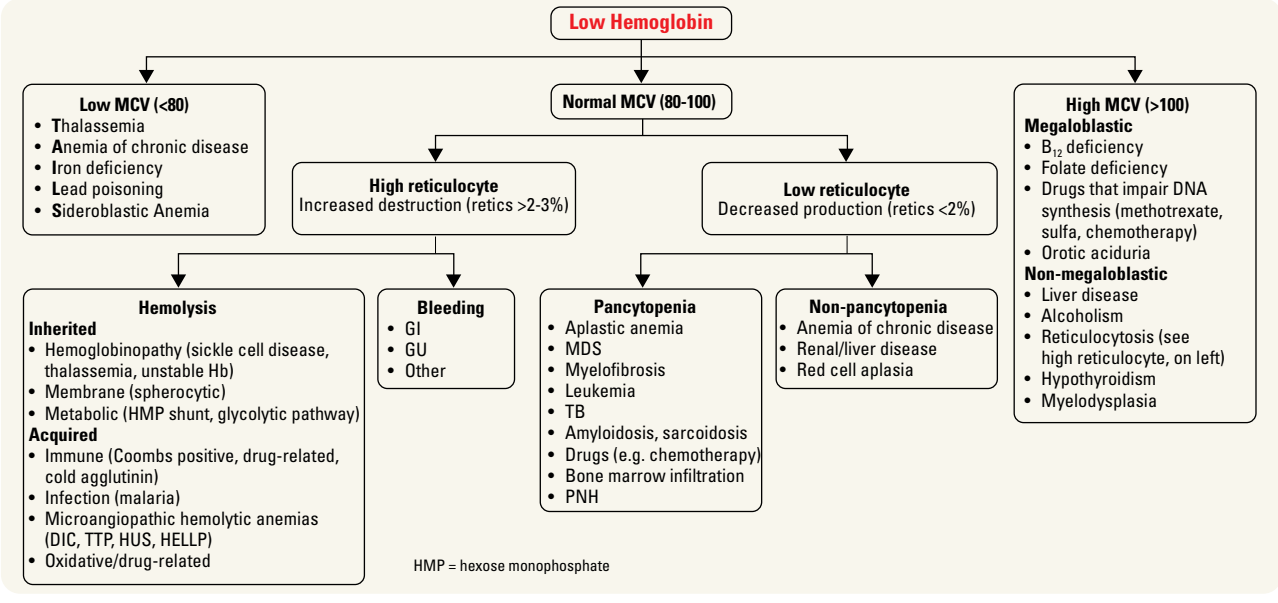

**Figure 2. Approach to anemia – classification by size of RBC**

### Clinical Features

- history
  - symptoms of anemia: fatigue, headache, light-headedness, malaise, weakness, decreased exercise tolerance, dyspnea, palpitations, dizziness, tinnitus, and syncope
  - acute vs. chronic, bleeding, systemic illness, diet (Fe, $B_{12}$ sources), alcohol, and family history
  - menstrual history: menorrhagia, menometrorrhagia
  - rule out pancytopenia (recurrent infection, mucosal bleeding, easy bruising)
- physical signs
  - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L (<9 g/dL), ocular bruits at Hb <55 g/L (<5.5 g/dL), angular cheilitis, jaundice
  - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
  - dermatologic: ecchymosis, petechiae, pallor in palmar skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes (spooning), and glossitis
  - splenomegaly, lymphadenopathy

**Reticulocytes**

- Reticulocytes are immature erythrocytes and are markers of erythrocyte production (↑ colour, ↓ central pallor, ↑ size)
- The reticulocyte count should always be interpreted in the context of Hb concentration
- Should normally increase when there is a decrease in RBC
- With blood loss, reticulocytes should increase 2-3x initially and then 5-7x over the next week
- A normal reticulocyte count in anemia should be interpreted as a sign of decreased production, and may result from BM infiltration, nutritional deficiency, or other causes

### Investigations

- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential
- reticulocyte count and blood smear/film
- rule out nutritional deficit, gastrointestinal, and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see *Microcytic Anemia*, H13, *Normocytic Anemia*, H17, *Hemolytic Anemia*, H18, and *Macrocytic Anemia*, H23)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

## Erythrocytosis

### Definition

- an increase in the number of RBCs: Hb >185 g/L or Hct >52% (males); Hb >165 g/L or Hct >47% (females and African males)

### Etiology

- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, and "stress" (Gaisböck's syndrome)
- absolute erythrocytosis

**Table 5. Etiology of Erythrocytosis**

| Primary | Secondary | Inappropriate Production of Erythropoietin |
|---|---|---|
| **Polycythemia Vera (PV)** (see *Polycythemia Vera*, H42) | **Physiologic (poor tissue oxygenation/ hypoxia)**<br>Carbon monoxide poisoning<br>Heavy smoking<br>High altitude<br>**Pulmonary Disease**<br>COPD<br>Sleep apnea<br>Pulmonary hypertension<br>**Cardiovascular Disease**<br>R to L shunt (Eisenmenger syndrome)<br>RBC defects (Hb with increased $O_2$ affinity, methemoglobinemia) | **Tumours**<br>Hepatocellular carcinoma<br>Renal cell carcinoma<br>Cerebellar hemangioblastoma<br>Pheochromocytoma<br>Uterine leiomyoma<br>Ovarian tumour<br>**Other**<br>Polycystic kidney disease<br>Post-kidney transplant<br>Hydronephrosis<br>Androgens<br>Exogenous erythropoietin |

### Clinical Features
- secondary to high red cell mass and hyperviscosity
  - headache, dyspnea, dizziness, tinnitus, visual disturbances, hypertensive symptoms, and numbness/tingling
  - symptoms of angina, congestive heart failure, and aquagenic pruritus (only in MPNs)
- thrombosis (venous or arterial) or bleeding (seen with acquired vWD or acquired platelet dysfunction in MPNs)
- physical findings
  - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

### Investigations
- serum erythropoietin (EPO): differentiates primary (low/normal) from other etiologies (elevated)
  - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
    - only send if low/normal EPO level
- ferritin (iron deficiency can mask the diagnosis; if iron deficient with reticulocytosis, suggestive of PV)

### Treatment
- if primary: see *Polycythemia Vera*, H42
- if secondary: treat underlying cause
  - $O_2$ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours
  - often cardiologists will be hesitant to treat high Hct in cyanotic patients

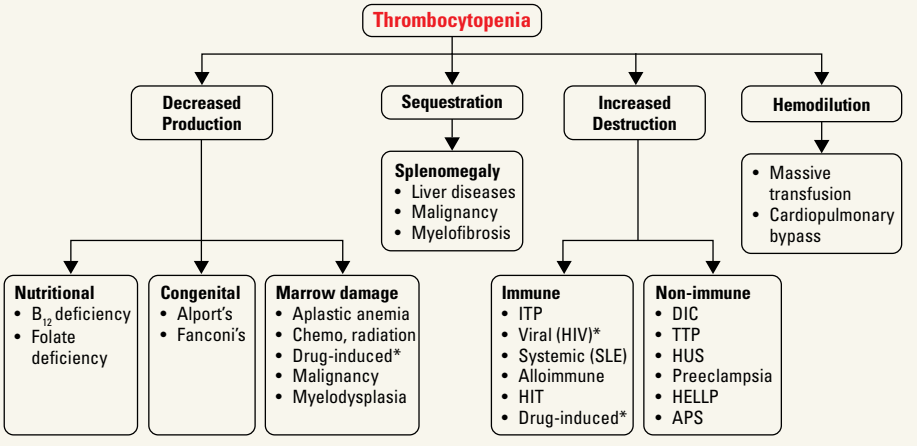
## Thrombocytopenia

### Definition
- platelet count <150 x $10^9$/L

### Clinical Features
- history: mucocutaneous bleeding (easy bruising, gingival bleeding), epistaxis, peri-operative bleeding (including dental procedures), heavy menstrual bleeding, and peripartum bleeding
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura, and wet purpura
- see *Disorders of Primary Hemostasis*, H27 for complications

### Investigations
- CBC and differential
- blood film
  - rule out factitious thrombocytopenia (platelet clumping or platelet satellitism)
  - decreased production: other cell line abnormalities, blasts (suggesting myeloid malignancy), hypersegmented PMNs (suggesting megaloblastic anemia), and leukoerythroblastic changes (suggesting BM infiltration or fibrosis)
  - increased destruction: large platelets (often seen in ITP), schistocytes (seen in MAHA/TMA)
- workup for nutritional deficiencies: $B_{12}$, RBC folate
- PT/INR, aPTT, and fibrinogen if DIC suspected
- LFT
- abdominal ultrasound to look for splenomegaly

### Treatments
- life threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see *Immune Thrombocytopenic*, H27



**Rule-of-thumb**: a deficit in all cell lines suggests decreased production, sequestration, or hemodilution. A deficit in platelets and RBCs suggests non-immune destruction or Evan's syndrome. An isolated thrombocytopenia suggests an immune-mediated process. In hospitalized patients, drugs and infection account for the majority of cases of thrombocytopenia

**Must rule out factitious thrombocytopenia:** platelet clumping secondary to EDTA antibodies present in serum. This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA)

**Wet vs. Dry Purpura**
Wet purpura: hemorrhaging of mucous membranes
Dry purpura: bruising or petechiae on skin surface

*In hospitalized patients most common causes of thrombocytopenia are drugs and infection

APS = antiphospholipid antibody syndrome; DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes, low platelet count; HIT = heparin induced thrombocytopenia; HUS = hemolytic uremic syndrome; ITP = idiopathic thrombocytopenic purpura; SLE =systemic lupus erythematosus; TTP = thrombotic thrombocytopenic purpura

**Figure 3. Approach to thrombocytopenia**

# Thrombocytosis

## Definition
- platelet count >400 x $10^9$/L
- primary thrombocytosis (uncommon): due to myeloproliferative neoplasms (e.g. CML, polycythemia vera, primary myelofibrosis, and essential thrombocytosis; rarely associated with MDS)
- reactive/secondary thrombocytosis (common): acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms, and ischemic injury)

## Clinical Features
- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, and constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, and aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative neoplasms (MPNs)

## Investigations
- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS

## Treatment
- primary: ASA ± cytoreductive agents (e.g. hydroxyurea, anagrelide, interferon-α)
- secondary: treat underlying cause

# Pancytopenia

## Definition
- a decrease in all hematopoietic cell lines

## Clinical Features
- anemia: fatigue (see *Anemia*, H6)
- leukopenia: recurrent infections (see *Neutropenia*, H9)
- thrombocytopenia: mucocutaneous bleeding (see *Thrombocytopenia*, H7)

## Investigations
- CBC, peripheral blood film, serum ferritin concentration, $B_{12}$, folate
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- workup as per Figure 4 and presenting symptoms/physical exam
- if reactive process has been ruled out, bone marrow biopsy may be required

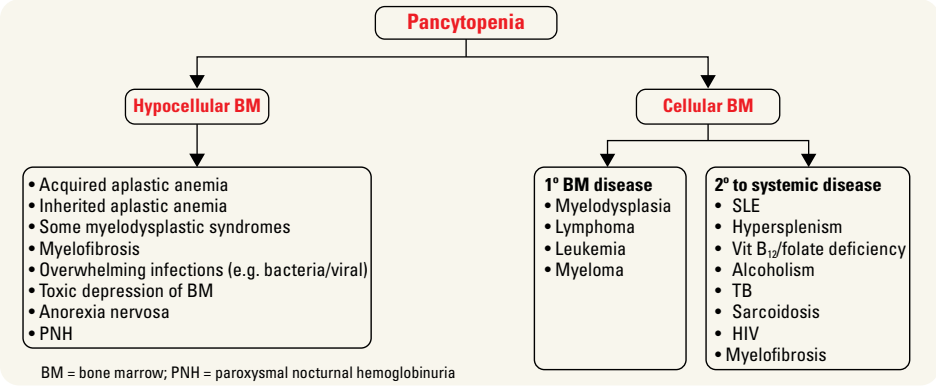

**Figure 4. Approach to pancytopenia**

# Neutrophilia

## Definition
- variable definition, but generally an absolute neutrophil count (ANC) >7.7 x $10^9$/L (WHO definition)

## Etiology
- primary neutrophilia
  - chronic myeloid leukemia (CML)
  - other myeloproliferative disorders: PV, ET, myelofibrosis
  - hereditary neutrophilia (autosomal dominant)
  - chronic idiopathic neutrophilia in otherwise healthy patients
  - leukocyte adhesion deficiency
- secondary neutrophilia
  - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  - obesity
  - infection: leukocytosis with left shift ± toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
  - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, and burns
  - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
  - medications: glucocorticoids, β-agonists, lithium, G-CSF

## Clinical Features
- look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  - including lymphadenopathy and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

## Investigations
- CBC and differential: mature neutrophils or bands >20% of total WBC suggests infection/inflammation
- blood film: Döhle bodies, toxic granulation, and cytoplasmic vacuoles in infection
- may require bone marrow biopsy if MPN suspected

## Treatment
- directed at underlying cause

# Neutropenia

## Definition
- mild: ANC 1.0-1.5 x $10^9$/L
- moderate: ANC 0.5-1.0 x $10^9$/L (risk of infection starts to increase)
- severe: ANC <0.5 x $10^9$/L
- profound: ANC <0.1 x $10^9$/L for >7 d

Absolute Neutrophil Count (ANC) = WBC count x (%PMNs + %bands)

Beware of fever + ANC <0.5 x $10^9$/L = FEBRILE NEUTROPENIA

### Etiology

**Table 6. Etiology of Neutropenia**

| Decreased Production | Peripheral Destruction/Sequestration | Excessive Margination (Transient Neutropenia) |
|---|---|---|
| **Infection**<br>Viral hepatitis, Epstein-Barr virus, HIV, TB, typhoid, malaria<br>**Hematological Diseases**<br>Idiopathic, aplastic anemia, myelofibrosis, BM infiltration, cyclic, PNH, MDS, immune-mediated<br>**Drug-Induced**<br>Alkylating agents, antimetabolites, anticonvulsants, antipsychotics, anti-inflammatory agents, anti-thyroid drugs<br>**Toxins/Chemicals**<br>High dose radiation, benzene, dichloro diphenyl trichloroethane (DDT)<br>**Nutritional Deficiency**<br>$B_{12}$, folate<br>**Idiopathic**<br>Constitutional neutropenia, benign cyclic neutropenia | Anti-neutrophil antibodies<br>Spleen or lung trapping<br>Autoimmune disorders: rheumatoid arthritis (Felty's syndrome), SLE<br>Granulomatosis with polyangiitis (formerly Wegener's)<br>Drugs: haptens (e.g. α-methyldopa) | Idiopathic (most common)<br>Overwhelming bacterial infection<br>Hemodialysis<br>Cardiopulmonary bypass<br>Racial variation (e.g. African or Ashkenazi Jewish descent) |

**Prophylactic Hematopoietic Colony-Stimulating Factors on Mortality and Infection**
Ann Intern Med 2007;147:400-411
**Purpose**: To review the effects of colony-stimulating factor (CSF) on mortality, infections, and febrile neutropenia in patients undergoing chemotherapy or stem-cell transplant (SCT).
**Study Selection**: 148 RCTs comparing the effects of CSFs to either placebo or no therapy were included. Prophylactic CSFs were given concurrently with or after initiation of chemotherapy.
**Results**: There were no differences in all-cause mortality or infection-related death between CSF and placebo groups. Compared to placebo or no therapy, CSFs reduced infection rate (median rate 38.9% vs. 43.1%; rate ratio 0.85), microbiologically documented infections (MR 23.5% vs. 28.6%; rate ratio 0.86), and febrile neutropenia (MR 25.3% vs. 44.2%; rate ratio 0.71).
**Conclusions**: Prophylactic CSFs decrease infection rates and episodes of febrile neutropenia in patients undergoing chemotherapy or SCT, but have no effect on mortality.

### Clinical Features
- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. *S. aureus*, Gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

### Investigations
- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

### Treatment
- regular dental care: chronic gingivitis and recurrent stomatitis are major sources of morbidity
- treatment of febrile neutropenia
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, and methotrexate)

**G-CSF = Neupogen® = filgrastim**

## Lymphocytosis

### Definition
- absolute lymphocyte count >4.0 x $10^9$/L

### Etiology
- infection (reactive lymphocytosis)
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
- smoking
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. rheumatoid arthritis)
- neoplasm (e.g. CLL, B cell lymphocytosis of undetermined significance)

Presence of atypical lymphocytes suggests viral infection

Presence of smudge cells suggests a lymphoproliferative disorder if persistently elevated above 5.0 x $10^9$/L for >3 mo; consider flow cytometry of peripheral blood

### Investigations
- CBC, peripheral smear assessing lymphocyte morphology

### Treatment
- treat underlying cause

# Lymphopenia

### Definition
- absolute lymphocyte count <1.0 x $10^9$/L

### Etiology
- older age
- idiopathic CD4+ lymphocytopenia
- radiation
- HIV/AIDS, hepatitis B, hepatitis C
- malignancy/chemotherapeutic agents
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)

### Clinical Features
- opportunistic infections (see Infectious Diseases, ID32)

### Treatment
- treat underlying cause
- treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see Infectious Diseases, ID28)

# Eosinophilia

**Basophilia and/or Eosinophilia**
Can be an indicator of CML or other myeloproliferative neoplasm, associated with pruritus due to excessive histamine production

### Definition
- absolute eosinophil count >0.5 x $10^9$/L

### Etiology
- primary: due to clonal bone marrow disorder
  - if no primary etiology identified, classified as hypereosinophilic syndrome
    - 6 mo of eosinophilia (count >1.5 x $10^9$/L) with no other detectable causes and end organ damage
    - can involve heart, bone marrow, and CNS
- secondary
  - most common causes are parasitic (usually helminth) infections and allergic reactions
  - less common causes
    - collagen vascular diseases (e.g. RA, polyarteritis nodosa, see Rheumatology, RH20)
    - respiratory causes (asthma, eosinophilic pneumonia, and Churg-Strauss)
    - cholesterol emboli
    - hematologic malignancy: see *Chronic Myeloid Leukemia*, H40 and *Hodgkin Lymphoma*, H45
    - adrenal insufficiency, see Endocrinology, E36
    - medications (penicillins)
    - atopic dermatitis

### Treatment
- treat underlying cause
- ensure strongyloides serology is collected to rule out infection before initiating steroids for patients at risk

# Agranulocytosis

### Definition
- absolute neutrophil count is <100/μL per microlitre

### Etiology
- associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
  - immune-mediated destruction of circulating granulocytes by drug-induced antibodies or direct toxic effects upon marrow granulocytic precursors

### Clinical Features
- abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

### Prognosis
- high fatality without vigorous treatment

### Investigations/Treatment
- discontinue offending drug
- pan-culture and screen for infection if patient is febrile (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
- consider bone marrow aspirate and biopsy if cause unclear
- consider G-CSF

# Leukemoid Reaction

- blood findings resembling those seen in certain types of leukemia which reflect the response of healthy BM to cytokines released due to infection or trauma
- leukocytosis >50 x $10^9$/L, marked left shift (myelocytes, metamyelocytes, and bands in peripheral blood smear)

# Approach to Lymphadenopathy

## History

- constitutional/B-symptoms: seen in TB, lymphoma, other malignancies
- growth pattern: acute vs. chronic
- exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), and high risk behaviours (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

**Constitutional/B-Symptoms**
- Unexplained temperature >38°C
- Unexplained weight loss (>10% of body weight in 6 mo)
- Night sweats

## Clinical Features

- determine if lymphadenopathy is localized or generalized
- localized: typically reactive or neoplastic
  - cervical (bacterial/mycobacterial infections, ENT malignancies, and metastatic cancer)
  - supraclavicular
    - right (mediastinal, bronchogenic, esophageal cancer)
    - left (gastric, gall bladder, pancreas, renal, and testicular/ovarian cancer)
  - axillary (cat scratch fever, breast cancer, and metastatic cancer)
  - epitrochlear (infections, sarcoidosis, and lymphoma)
  - check for splenomegaly, constitutional symptoms

**Drugs that can cause Lymphadenopathy**
- Allopurinol
- Atenolol
- Captopril
- Carbamazepine
- Cephalosporins
- Gold
- Hydralazine
- Penicillin
- Phenytoin
- Primidone
- Pyrimethamine
- Quinidine
- Sulfonamides
- Sulindac

## Investigations

- CBC and differential, blood film
- if generalized, consider tuberculin test, HIV RNA, VDRL, Monospot®/EBV serology, ANA, and imaging
- if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → biopsy)
- excisional biopsy is preferred as it preserves node architecture (essential for diagnosing lymphoma)
- in areas difficult to access (retroperitoneal, mediastinal/hilar) multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (excisional biopsy is the gold standard)
  - FNA is helpful for recurrence of solid tumour malignancy
  - imaging such as U/S or CT can provide more info, but generally adds little to diagnosis

**Table 7. Inflammatory vs. Neoplastic Lymph Nodes**

| Feature | Inflammatory | Neoplastic |
|---|---|---|
| Consistency | Fluctuant/soft | Firm/hard |
| Mobility | Mobile | Matted/immobile |
| Tenderness | Tender | Non-tender |
| Size | <2 cm | >2 cm |

*Note: these classifications are not absolute; lymphoma and CLL nodes can feel rubbery and are frequently mobile, non-tender

**Table 8. Differential Diagnosis of Generalized Lymphadenopathy**

| Reactive | Inflammatory | Neoplastic |
|---|---|---|
| Bacterial (TB, Lyme, brucellosis, cat scratch disease, and syphilis) | Collagen disease (RA, dermatomyositis, SLE, vasculitis, and Sjögren's) | Lymphoproliferative disorder/ lymphoma |
| Viral (EBV, CMV, HIV) | Drug hypersensitivity | Metastatic cancer |
| Parasitic (toxoplasmosis) | Sarcoidosis, amyloidosis | Histiocytosis X |
| Fungal (histoplasmosis) | Serum sickness | |

# Approach to Splenomegaly

**Table 9. Differential Diagnosis of Splenomegaly**

| Increased Demand for Splenic Function | | | Congestive | Infiltrative |
|---|---|---|---|---|
| **Hematological**<br>Nutritional anemias<br>Hemoglobinopathies<br>Hemolysis<br>Spherocytosis<br>Sequestration crisis<br>Elliptocytosis | **Infectious**<br>Viral e.g. EBV, HIV/AIDS, CMV<br>Bacterial e.g. Bacterial endocarditis, TB<br>Parasitic e.g. Malaria, Histoplasmosis, Leishmaniasis<br>Fungal | **Inflammatory**<br>SLE<br>Sarcoidosis<br>Felty syndrome<br>Still's disease | **Cirrhosis**<br>Portal HTN<br>Portal vein obstruction (including right heart failure)<br>Splenic vein thrombosis | **Non-Malignant**<br>Benign metaplasia<br>Cysts<br>Amyloidosis, Sarcoidosis<br>Hamartomas<br>Vascular abnormalities<br>Lysosomal storage diseases (Gaucher's, Niemann-Pick)<br>Glycogen storage diseases<br>**Malignant**<br>Leukemia (CML, CLL)<br>Lymphoproliferative disease<br>Hodgkin lymphoma<br>Myeloproliferative disorders<br>Metastatic tumour |

The underlined conditions cause *massive splenomegaly* (spleen crosses midline or reaches pelvis)

**Causes of Splenomegaly**

**CHINA**
**C**irrhosis/Congestion (portal HTN)
**H**ematological
**I**nfectious
**N**eoplasm (malignant, non-malignant)
**A**utoimmunue

### History
- constitutional symptoms, feeling of fullness in LUQ, and early satiety
- signs or symptoms of infection (e.g. mononucleosis) or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

### Clinical Features
- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube's space, and Nixon's method) and palpation
- associated lymphadenopathy or hepatomegaly
- signs of CHF

### Investigations
- CBC and differential, blood film
- as indicated: liver enzymes (AST, ALT, ALP, and GGT) and/or LFTs (platelet, INR, albumin, and bilirubin), reticulocyte count, Monospot®/EBV, haptoglobin, LDH, infectious, and autoimmune workup
- imaging
  - ultrasound of abdomen/liver to assess for cirrhosis and portal vein thrombosis (if positive, refer to hepatology)
  - echo for cardiac function
  - CT to rule out lymphoma and assess splenic lesions

# Microcytic Anemia

- MCV <80 fL
- see Figure 2, *Approach to Anemia*, H6

**Table 10. Iron Indices and Blood Film in Microcytic Anemia**

| | Lab Tests | | | | | Blood Film |
|---|---|---|---|---|---|---|
| | Ferritin | Serum Iron | TIBC | % saturation | RDW | |
| **Iron Deficiency Anemia** | ↓↓ | ↓ | ↑ | ↓ | ↑ (>15) | Hypochromic, microcytic |
| **Anemia of Chronic Disease** | N/↑ | ↓ | ↓ | N | N | Normocytic/microcytic |
| **Sideroblastic Anemia** | N/↑ | ↑ | N | N/↑ | ↑ | Dual population<br>Basophilic stippling |
| **Thalassemia** | N/↑ | N/↑ | N | N/↑ | N/↑ | Hypochromic, microcytic<br>Basophilic stippling<br>Poikilocytosis |

**Causes of Microcytic Anemia**

**TAILS**
**T**halassemia
**A**nemia of chronic disease
**I**ron deficiency
**L**ead poisoning
**S**ideroblastic anemia

# Iron Metabolism

### Iron Intake (Dietary)
- average North American adult diet = 10-20 mg iron (Fe) daily
- steady state absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid, ascorbic acid (vitamin C) and reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males more likely to have positive Fe balance; up to 20% of menstruating females have negative Fe balance

## Iron Absorption and Transport

- dietary iron is absorbed in the duodenum (e.g. absorption impaired in IBD and Celiac disease)
- in circulation the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the bone marrow

## Iron Levels

- hepcidin is a hormone produced by hepatocytes that regulates systemic iron levels
  - binds to iron exporter ferroportin (on duodenal enterocytes and reticuloendothelial cells) and induces its degradation, thereby inhibiting iron export into circulation (diminished absorption of iron and iron trapping in reticuloendothelial system cells)
  - hepcidin production is:
    - increased in states of iron overload (inhibiting additional iron absorption) and inflammation (mediating anemia of chronic inflammation through iron trapping)
    - decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

## Iron Storage

- ferritin
  - ferric iron ($Fe^{3+}$) complexed to a protein called apoferritin (liver, spleen, and bone marrow are main ferritin storage sites)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated despite low Fe stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is main source of hemosiderin storage

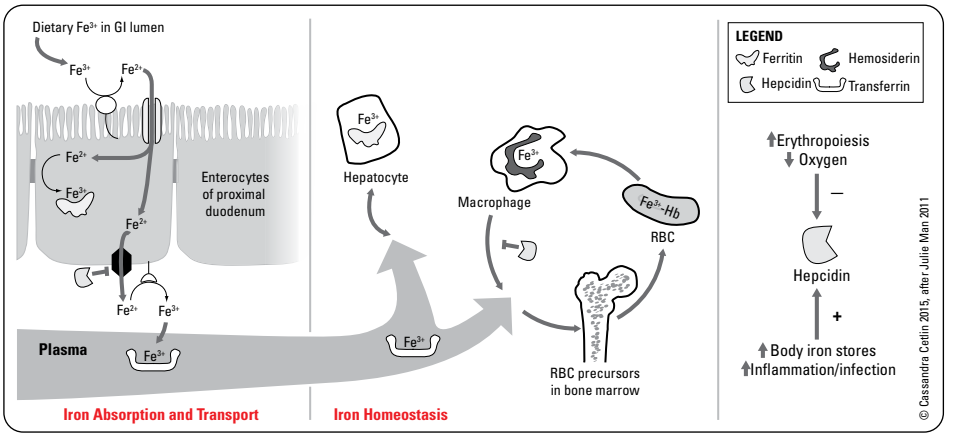

**Figure 5. Iron metabolism**

## Iron Indices

- bone marrow aspirate: gold standard test for assessment of iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
  - decreased in iron deficiency anemia
  - elevated in infection, inflammation, malignancy, liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
- total iron binding capacity (TIBC): indirect measure of total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - increased TIBC has high specificity for decreased iron, low sensitivity
- saturation
  - serum Fe divided by TIBC, expressed as a proportion or a percentage
- soluble transferrin receptor (sTfR)
  - reflects the availability of iron at the tissue level
  - the transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some are cleaved off and are present in circulation as sTfR
  - in iron deficient states more transferrin receptors are expressed on erythroblasts leading to an increase in sTfR
  - low in reduced erythropoiesis and iron overload
  - useful in determining iron deficiency in the setting of chronic inflammatory disorders (see *Iron Deficiency Anemia,* H15)

# Iron Deficiency Anemia

- see Pediatrics, P43
- most common cause of anemia in North America

## Etiology

- increased demand
  - increased physiological need for iron in the body (e.g. pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology in the developed world)
  - cow's milk (infant diet), "tea and toast" diet (elderly), absorption imbalances, post-gastrectomy, malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis, and *H.pylori* infection)
- increased losses
  - hemorrhage
    - obvious causes: menorrhagia, abnormal uterine bleeding, and frank GI bleed
    - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - chronic intravascular hemolysis (e.g. PNH, cardiac valve RBC fragmentation)

## Clinical Features

- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see *Anemia*, H6
- brittle hair, nail changes (brittle, koilonychia)
- pica (appetite for non-food substances e.g. ice, paint, and dirt)
- restless leg syndrome

**Plummer-Vinson Syndrome**
- Dysphagia (esophageal)
- Glossitis
- Iron deficiency anemia
- Stomatitis

## Investigations

- iron indices, including soluble transferrin receptor
  - low ferritin (<18 µg/L) is diagnostic of iron deficiency
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms, anisocytosis
  - target cells
- bone marrow (gold standard but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

Iron deficiency anemia is a common presentation of chronic lower GI bleeds (right-sided colorectal cancer, angiodysplasia, etc.)

In males and in post-menopausal women, a GI workup is always warranted (gastroscopy, colonoscopy)

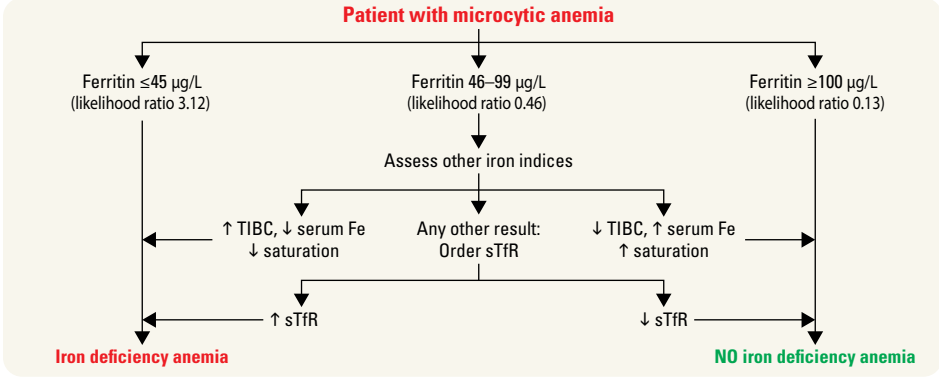

**Figure 6. Approach to interpreting iron indices**
Adapted from: Am Fam Physician 2007;75:671-678

## Treatment

- treat underlying cause
- supplementation
  - oral (capsules, syrup)
    - ferrous sulphate 325 mg OD (65 mg elemental iron), ferrous gluconate 300 mg OD (35 mg elemental iron), or ferrous fumarate 300 mg OD (100 mg elemental iron), polysaccharide iron complex (150 mg elemental iron), heme iron polypeptide (11 mg elemental iron)
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - recent studies demonstrate alternate day dosing may be superior to daily or more frequent dosing, due to improved absorption, though this is still an area of investigation
    - oral iron should be taken with citrus juice (vitamin C) to enhance absorption
  - IV (iron sucrose or dextran) can be considered if patient cannot tolerate or absorb oral iron
- monitoring response
  - reticulocyte count will begin to increase after one wk
  - Hb normalizes by 10 g/L per wk (if no blood loss)

# Anemia of Chronic Inflammation

### Etiology
- infection, malignancy, inflammatory, and rheumatologic disease
- chronic renal and liver disease
- endocrine disorders (e.g. DM, hypothyroidism, hypogonadism, and hypopituitarism)

### Pathophysiology
- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  - hepatic hepcidin production is increased in inflammatory processes, trapping iron in enterocytes and macrophages (via ferroportin inhibition), see Figure 5
  - reduced plasma iron levels make iron relatively unavailable for new hemoglobin synthesis
  - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present i.e. RBC survival is modestly decreased

### Investigations
- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen, and platelets)
- peripheral blood
  - mild: usually normocytic and normochromic
  - moderate: may be microcytic and normochromic
  - severe: may be microcytic and hypochromic
  - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- "classic" serum iron indices
  - serum iron and TIBC low or normal, % saturation low
  - serum ferritin is normal or increased
- bone marrow
  - normal or increased iron stores
  - decreased or absent staining for iron in erythroid precursors

### Treatment
- treat underlying disease; only treat in patients who would benefit from a higher hemoglobin
- IV iron if no benefit from PO iron (overcomes sequestration in enterocytes)
- erythropoietin indicated in chronic renal failure; not to be used if patient has concomitant curative solid tumour malignancy; ensure Hb target <110 g/L

# Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

### Sideroblasts
- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- "normal": granules are small and randomly spread in the cytoplasm
- "ring": iron deposits in mitochondria, forming large, abnormal granules that surround the nucleus
  - the hallmark of sideroblastic anemia

### Etiology
- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
  - refractory anemia with ringed sideroblasts: a subtype of MDS (see *Myelodysplastic Syndromes*, H39)
  - may be a preleukemic phenomenon (1-2% transform to AML)
- reversible
  - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, and hypothyroidism

### Clinical Features
- anemia symptoms (see *Anemia*, H6)
- hepatosplenomegaly, evidence of iron overload

### Investigations
- serum iron indices
  - increased serum $Fe^{2+}$, normal TIBC, increased ferritin, increased sTfR
- blood film/bone marrow biopsy
  - ringed sideroblasts (diagnostic hallmark)
  - RBCs are hypochromic; can be micro-, normo-, or macrocytic
  - anisocytosis, poikylocytosis, basophilic stippling

### Treatment
- depends on etiology
  - X-linked: high dose pyridoxine (vitamin $B_6$) in some cases
  - acquired: EPO and G-CSF
  - reversible: remove precipitating cause
- supportive transfusions for severe anemia

# Lead Poisoning

## Definition/Etiology
- blood lead levels greater than 80 µg/dL, possible symptomatology at 50 µg/dL
- identify source: consider occupational history, exposures history, and utensil history

## Clinical Features
- abdominal pain, constipation, irritability, and difficulty concentrating

## Treatment
- chelation therapy: dimercaprol and EDTA are first line agents

Consider lead poisoning in any child with microcytic anemia who lives in a house built before 1977

**Features of Lead Poisoning**

**LEAD**
**L**ead lines on gingivae and epiphyses of long bones on x-ray
**E**ncephalopathy and **E**rythrocyte basophilic stippling
**A**bdominal colic and microcytic **A**nemia (sideroblastic)
**D**rops (wrist and foot drop)

# Normocytic Anemia

- MCV 80-100 fL
- see Figure 2, *Approach to Anemia*, H6

# Aplastic Anemia

## Definition
- destruction of hematopoietic cells of the bone marrow leading to pancytopenia and hypocellular bone marrow

## Etiology

**Table 11. Etiology of Aplastic Anemia**

| Congenital | Acquired | |
|---|---|---|
| Fanconi's anemia<br>Shwachman-Diamond syndrome | **Idiopathic**<br>Often T-cell mediated<br>**Drugs**<br>Dose-related (i.e. chemotherapeutics)<br>Idiosyncratic (chloramphenicol, anti-malarials, and phenylbutazone)<br>**Toxins**<br>Benzene/organic solvents<br>DDT, insecticides | **Ionizing Radiation**<br>**Post-Viral Infection**<br>Parvovirus B19, EBV, HDV, HEV, HBV, HHV6, HIV<br>**Autoimmune** (rare)<br>SLE, Graft-versus-host disease<br>**Others**<br>PNH, pregnancy, anorexia nervosa, and thymoma |

**Causes of Normocytic Anemia**

**ABCD**
**A**cute blood loss
**B**one marrow failure
**C**hronic disease
**D**estruction (hemolysis)

## Clinical Features
- can present acutely or insidiously
- symptoms of anemia (see *Anemia*, H6), thrombocytopenia (see *Thrombocytopenia*, H7), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)

## Investigations
- exclude other causes of pancytopenia (see Figure 4), including PNH (50% of AA patients have PNH+ stem cell clones)
- CBC
  - anemia, neutropenia or thrombocytopenia (any combination) ± pancytopenia
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- bone marrow
  - aplasia or hypoplasia of marrow cells with fat replacement
  - decreased cellularity

## Treatment
- remove offending agents
- supportive care (red cell and platelet transfusions, antibiotics)
  - judicious use so as to not increase the risk of immune sensitization to blood products
  - iron chelation therapy for iron overload (build up of iron after multiple >20 units of blood transfusion)
- immunosuppressive therapy (for idiopathic aplastic anemia)
  - horse or rabbit anti-thymocyte globulin: 40-50% of patients respond
  - + cyclosporine (for improved response and survival)
- allogeneic bone marrow transplant
- growth factors: e.g. Eltrombopag (TPO receptor agonist), G-CSF, and EPO not effective

# Hemolytic Anemia

## Definition
- anemia due to a shortened survival of circulating RBCs, usually defined as <100 d
- uncommon cause for anemia (<5% of cases) with many etiologies (>200)

## Classification
- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal hemoglobin synthesis (thalassemias, hemoglobinopathies)
- acquired
  - immune
    - autoimmune: warm vs. cold autoimmune hemolytic anemias (AIHA), see Table 14 *Classification of AIHA*, H22
    - alloimmune: hemolytic disease of the fetus/newborn and post-transfusion
  - non-immune
    - MAHA/TMA, now known as TMA: thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS, aHUS, TTP, preeclampsia/HELLP, vasculitides, and malignant hypertension
    - other causes: PNH, hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, and mechanical heart valves
- also classified as intravascular or extravascular
  - intravascular: MAHA/TMA (e.g. TTP, DIC), infections (malaria, Clostridium), and PNH
  - extravascular: RBCs are coated with antibodies (AIHA) or have an abnormal membrane structure/ shape or inclusions

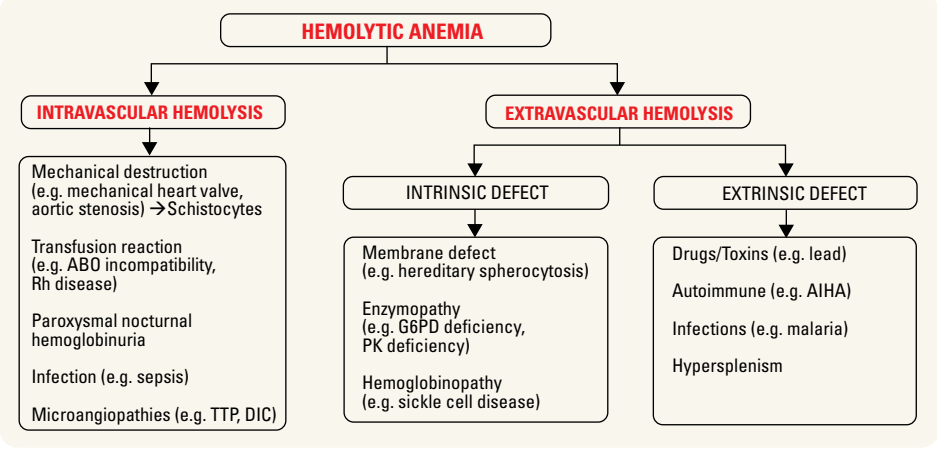

**Figure 7. Hemolytic anemia**

## Clinical Features Specific to HA
- jaundice
- dark urine (hemoglobinuria, bilirubin)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

## Investigations

**Table 12. Investigations for Hemolytic Anemia**

| Screening Tests | Tests Specific For Intravascular Hemolysis |
|---|---|
| Increased LDH | Schistocytes on blood film |
| Decreased haptoglobin | Free hemoglobin in serum |
| Increased unconjugated bilirubin | Methemalbuminemia (heme + albumin) |
| Increased urobilinogen | Hemoglobinuria (immediate) |
| Reticulocytosis | Hemosiderinuria (delayed) – most sensitive |
| **Tests Specific for Extravascular Hemolysis** | |
| **Direct Antiglobulin Test (DAT) (direct Coombs)**<br>Detects IgG or complement on the surface of RBC<br>Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination<br>Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction<br>**Indirect Antiglobulin Test (indirect Coombs)**<br>Detects antibodies in serum that can recognize antigens on RBCs<br>Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination<br>Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA | |

On blood film schistocytes reflect an intravascular hemolysis while spherocytes usually reflect an extravascular hemolysis

Disruption of the heme biosynthetic pathway causes the **porphyria** disorders

**Porphyrias**
Inherited or acquired disorder of defective heme synthesis leading to accumulation of porphyrin precursors. Typically present with non-specific clinical findings (abdominal pain, peripheral neuropathy, neuropsychiatric changes, and/or cutaneous photosensitivity)

**Heme Breakdown**

**Heme** → (Heme oxygenase) → **Biliverdin** → (Biliverdin reductase) → **Bilirubin**

**Laboratory Findings in HA**
- ↑ retics
- ↓ haptoglobin
- ↑ unconjugated bilirubin
- ↑ urobilinogen
- ↑ LDH

**Haptoglobin** is a circulating protein that mops up free hemoglobin, allowing its clearance in the spleen; when there is abundant free hemoglobin, haptoglobin is consumed, and levels decrease

**ThalasSEAmia**
β-Thal → prevalent in Mediterranean
α-Thal → prevalent in South East Asia (SEA) and Africa (α = Asia, Africa)

# Thalassemia

### Definition
- defects in production of the α or β chains of hemoglobin
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depend on specific gene and number of alleles affected
- common features
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film

### Pathophysiology
- defect may be in any of the Hb genes
  - normally 4α genes in total; 2 on each copy of chromosome 16
  - normally 2β genes in total; 1 on each copy of chromosome 11
  - fetal hemoglobin, HbF (α2γ2), switches to adult forms HbA (α2β2) and HbA2 (α2δ2) at 3-6 mo of life
  - HbA constitutes 97% of adult hemoglobin
  - HbA2 constitutes 3% of adult hemoglobin

# β-Thalassemia Minor (Thalassemia Trait)

### Definition
- defect in single allele of β gene (heterozygous for one normal β globin allele and one β globin thalassemic allele)
- common in people of Mediterranean and Asian descent

### Clinical Features
- usually asymptomatic; a palpable spleen is very rare

### Investigations
- Hb (100-140 g/L), MCV (<70 fL), Fe (normal), RBC count (normal)
- peripheral blood film – microcytosis basophilic stippling
- Hb electrophoresis
  - specific: HbA2 increased to 3.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

### Treatment
- no treatment required
- genetic counselling for patient and family

**Microcytosis in β-Thal Minor**
Microcytosis is much more profound and the anemia is much milder than that of iron deficiency

# β-Thalassemia Major

### Definition
- defect in both alleles of β gene (homozygous, autosomal recessive)

### Pathophysiology
- ineffective chain synthesis leading to ineffective erythropoiesis, hemolysis of RBCs, and increase in HbF

### Clinical Features
- initial presentation at age 6-12 mo when HbA (α2/β2) normally replaces HbF (α2/γ2)
  - severe anemia, jaundice
- iron overload due to compensatory gastrointestinal iron uptake progressing to hemochromatosis
  - secondary to repeated transfusions and ineffective erythropoiesis
  - leads to iron-induced organ damage
- stunted growth and development (hypogonadal dwarf)
- gross hepatosplenomegaly (due to extramedullary hematopoiesis)
- radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
  - skull x-ray has "hair-on-end" appearance
  - pathologic fractures common
- evidence of increased Hb catabolism (e.g. pigmented gallstones)
- death can result from:
  - untreated anemia (should transfuse)
  - infection (should identify and treat early)
  - iron overload (common): late complication from repeated transfusions and ineffective erythropoiesis

**Hemochromatosis Clinical Features**

**ABCDH**
**A**rthralgia
**B**ronze skin
**C**ardiomyopathy, cirrhosis of liver
**D**iabetes (pancreatic damage)
**H**ypogonadism (anterior pituitary damage)

### Investigations
- severe microcytic anemia (Hb <60 g/L)
- peripheral blood film: teardrop, target, hypochromatic, microcytic
- Hb electrophoresis
  - HbA: 0-10% (normal >95%)
  - HbA2 >2.5%
  - HbF: 90-100%

### Treatment
- lifelong regular transfusions to suppress endogenous erythropoiesis
- iron chelation (e.g. deferoxamine, deferasirox, and deferiprone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)
- folic acid supplementation if not transfused
- allogeneic bone marrow transplantation (potentially curative) or cord blood transplant
- splenectomy (now performed less frequently)

## β-Thalassemia Intermedia

### Definition
- clinical diagnosis in patients whose clinical manifestations are too mild to be classified as thalassemia major, but too severe to be classified as thalassemia minor

### Clinical Features
- wide variety of clinical phenotypes
- in most cases of thalassemia intermedia, both β-globin genes affected
- three main mechanisms account for the milder phenotype compared to thalassemia major: (1) subnormal (vs. absent) β-chain synthesis, (2) increased number of γ chains, (3) coinheritance of α thalassemia (in some cases)
- complications more commonly seen in thalassemia intermedia than thalassemia major include extramedullary hematopoiesis, leg ulcers, gallstones, thrombosis, pulmonary hypertension, and growth retardation

### Treatment
- most patients only require periodic transfusions, although regular transfusions may eventually be necessary in adulthood (third to fourth decade of life)
- folic acid supplementation if not transfused
- due to ineffective erythropoiesis leading to downregulation of hepcidin, iron chelation therapy is required since iron overload develops even without frequent transfusion

## α-Thalassemia

### Definition
- defect(s) in α genes
- similar geographic distribution as β-thalassemia, but higher frequency among Asians and Africans

### Clinical Features
- 1 defective α gene (aa/a-): clinically silent; normal Hb, normal MCV
- 2 defective α genes (cis: aa/-- or trans: a-/a-): decreased MCV, normal Hb
  - N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in Africa – this leads to increased risk of fetal hydrops in offspring of Asian patients vs. African patients
- 3 defective α genes (a-/--): HbH (β4) disease; presents in adults, decreased MCV, decreased Hb, and splenomegaly
- 4 defective α genes (--/--): Hb Barts (γ4) disease (hydrops fetalis); usually incompatible with life

### Investigations
- peripheral blood film – screen for HbH inclusion bodies with supravital stain
- electrophoresis can be used to identify HbH disease, but may miss 1- or 2-gene deletions; definitive diagnosis with DNA genotyping

### Treatment
- depends on degree of anemia, referral for genetic/prenatal counselling
  - 1 or 2 defective α genes: no treatment required
  - HbH disease: similar to β-thalassemia intermedia
  - HbBarts: no definitive treatment, majority of pregnancies terminated (fetal/maternal mortality risk), and intrauterine transfusion, stem cell transplants

## Sickle Cell Disease

### Definition
- autosomal recessive sickling disorders arise due to a mutant β-globin chain, most commonly caused by a Glu → Val substitution at position 6 (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
  - increased incidence of HbS allele with Sub-Saharan African, Indian, Middle Eastern or Mediterranean heritage (thought to be protective against malaria)
- sickle cell disease occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β-globin gene (compound heterozygote) – most commonly HbS-β-thal and HbSC disease

### Pathophysiology
- at low $pO_2$, deoxy HbS polymerizes leading to rigid crystal-like rods that distort membranes → 'sickles'
- the $pO_2$ level at which sickling occurs is related to the percentage of HbS present
- sickling aggravated by acidemia, increased $CO_2$, increased 2,3-DPG, fever, and osmolality

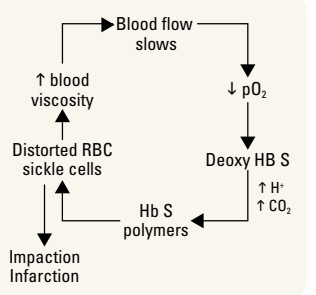

**Figure 8. Pathophysiology of sickling**

**Functional asplenism:** increased susceptibility to infection by encapsulated organisms
- *S. pneumoniae*
- *N. meningitidis*
- *H. influenza*
- *Salmonella* (osteomyelitis)

- fragile sickle cells then cause injury in two main ways
  1. fragile sickle cells hemolyze (nitric oxide depletion)
  2. occlusion of small vessels (hypoxia, ischemia-reperfusion injury)

## Clinical Features

- HbAS (sickle cell trait): patient will be asymptomatic except during extreme hypoxia or infection
  - increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- SCD-SS often presents with acute pain episode
  1. aplastic crises
     - toxins and infections (especially parvovirus B19) transiently suppress bone marrow
  2. splenic sequestration crises
     - usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
     - uncommon in adults due to asplenia from repeated infarction
  3. vaso-occlusive crises (infarction)
     - may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
     - can cause a stroke or a silent myocardial infarction
     - precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
  4. acute chest syndrome
- SCD-SC (most common compound heterozygote)
  - 1:833 live births in African-Americans, common in West Africa
  - milder anemia than HbSS
  - similar complications as HbSS, although typically milder and less frequent (exception is proliferative sickle retinopathy, glomerulonephritis, and avascular necrosis)
  - spleen not always atrophic in adults

**Organs Affected by Vaso-Occlusive Crisis**

| Organ | Problem |
|---|---|
| **Brain** | Ischemic or hemorrhagic stroke, vasculopathy |
| **Eye** | Hemorrhage, blindness |
| **Liver** | Infarcts, RUQ syndrome |
| **Lung** | Acute chest syndrome, long-term pulmonary hypertension |
| **Gallbladder** | Stones |
| **Heart** | Hyperdynamic flow murmurs |
| **Spleen** | Enlarged (child); atrophic (adult) |
| **Kidney** | Hematuria, loss of renal concentrating ability, proteinuria |
| **Intestines** | Acute abdomen |
| **Placenta** | Stillbirths |
| **Penis** | Priapism |
| **Digits** | Dactylitis |
| **Femoral and Humeral Head** | Avascular necrosis |
| **Bone** | Infarction, infection |
| **Ankle** | Leg ulcers |

## Investigations

- sickle cell prep (detects sickling of RBCs under the microscope in response to $O_2$ lowering agent): determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC, and other variants
- all newborns in developed countries typically screened for SCD

**Table 13. Investigations for Sickle Cell Disease**

| | HbAS | HbSS |
|---|---|---|
| **CBC** | Normal | Increased reticulocytes, decreased Hb, decreased Hct |
| **Peripheral Blood** | Normal; possibly a few target cells | Sickled cells |
| **Hb Electrophoresis** | HbA fraction of 0.65 (65%)<br>HbS fraction of 0.35 (35%) | No HbA, only HbS and HbF (proportions change with age); normal amount of HbA2 |

## Treatment

- genetic counselling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
- HbSS
  1. folic acid to prevent folate deficiency
  2. hydroxyurea to enhance production of HbF
     - mechanism of action: stops repression of Hb-γ chains and/or initiates differentiation of stem cells in which this gene is active
     - presence of HbF in the SS cells decreases polymerization and precipitation of HbS
     - N.B. hydroxyurea is cytotoxic and may cause bone marrow suppression
  3. treatment of vaso-occlusive crisis
     - supportive care: oxygen, hydration (reduces viscosity), correct acidosis, analgesics/opiates
     - indication for exchange transfusion: Hb <50-60 g/L, SCD complications (acute chest syndrome, aplastic crisis, hepatic or splenic sequestration, stroke), prevention of complications, pre-operative
     - less routinely: antimicrobials for suspected infection
  4. prevention of crises
     - establish diagnosis
     - avoid conditions that promote sickling (hypoxia, acidosis, dehydration, fever)
     - vaccination in childhood (pneumococcus, meningococcus, H. influenzae b)
     - prophylactic penicillin (age 3 mo-5 yr)
     - good hygiene, nutrition, and social support

**NIH Consensus Development Conference Statement: Hydroxyurea Treatment for Sickle Cell Disease**
*Ann Intern Med* 2008;148:932-938
**Efficacy**: Strong evidence for adolescents and adults and there is emerging data supporting its use in children. In the single RCT, the Hb level was higher in hydroxyurea recipients than placebo recipients after 2 yr (difference, 6 g/L), as was HbF (absolute difference, 3.2%). The median number of painful crises was 44% lower than in the placebo arm. The 12 observational studies that enrolled adults reported a relative increase in HbF of 4-20% and a relative reduction in crisis rates by 68-84%. Hospital admissions declined by 18-32%.
**Effectiveness**: Data is limited. It seems to be highly effective but is currently underutilized.
**Short-Term Harms (within 6 mo):** Dose-related leukopenia, thrombocytopenia, anemia, and decreased reticulocyte count. Others include decreased sperm production and dry skin.
**Long-Term Harms**: Birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug.

5. screen for complications
   - regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, and creatinine)
   - urinalysis annually (proteinuria and glomerulopathy)
   - transcranial doppler annually until 16 yr old (stroke prevention)
   - retinal examinations annually from 8 yr old (screen for retinopathy)
   - echocardiography once in late childhood/early adulthood (screen for pulmonary hypertension)

# Autoimmune Hemolytic Anemia

**Table 14. Classification of AIHA**

| | Warm (75-90% cases) | Cold |
|---|---|---|
| **Antibody Allotype** | IgG | IgM |
| **Agglutination Temperature** | 37°C | 4-37°C |
| **Direct Coombs Test (direct anti-globulin test)** | Positive for IgG ± complement | Positive for complement |
| **Etiology** | Idiopathic<br>Secondary to lymphoproliferative disorder (e.g. CLL, Hodgkin lymphoma)<br>Secondary to autoimmune disease (e.g. SLE)<br>Drug-induced (e.g. penicillin, quinine, methyldopa) | Idiopathic<br>Secondary to infection (e.g. mycoplasma pneumonia, EBV)<br>Secondary to lymphoproliferative disorder (e.g. macroglobulinemia, CLL) |
| **Blood Film** | Spherocytes | Agglutination |
| **Management** | Treat underlying cause<br>Folic acid<br>Corticosteroids<br>Immunosuppression<br>Splenectomy<br>Rituximab (2nd-line to steroids) | Treat underlying cause<br>Folic acid<br>Warm patient/avoid cold<br>Rituximab regiments (1st-line)<br>Plasma exchange (2nd-line for high IgM levels)<br>Low dose alkylating agents (chlorambucil, cyclophosphamide) or interferon may be useful but less effective |

# Microangiopathic Hemolytic Anemia Thrombotic Microangiopathy

### Definition
- hemolytic anemia due to intravascular fragmentation of RBCs

### Etiology
- see *Thrombotic Thrombocytopenic Purpura* and *Hemolytic Uremic Syndrome*, H30
- see *Disseminated Intravascular Coagulation*, H32
- eclampsia, HELLP syndrome, AFLP
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic antiphospholipid antibody syndrome

### Investigations
- blood film: evidence of hemolysis, schistocytes
- hemolytic workup (CBC, reticulocyte count, LDH, haptoglobin, indirect bilirubin)
- Coomb's test negative
- urine: hemosiderinuria, hemoglobinuria

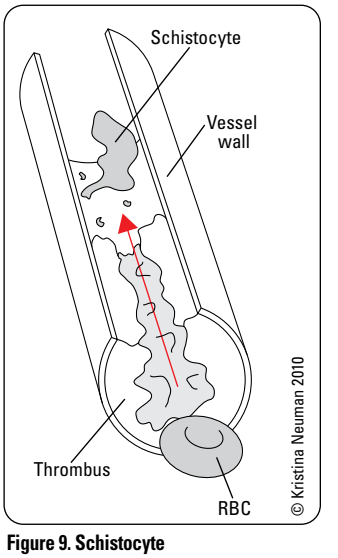

**Figure 9. Schistocyte**

# Hereditary Spherocytosis

- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
  - spleen makes defective RBCs more spherocytic (and more fragile) by membrane removal; also acts as site of RBC destruction
- autosomal dominant with variable penetrance

### Investigations
- blood film (shows spherocytes), osmotic fragility (increased), molecular analysis for spectrin gene

### Treatment
- in severe cases, splenectomy and vaccination against pneumococcus, meningococcus, and *H. influenza* type b (avoid in early childhood)

# Hereditary Elliptocytosis

### Definition/Etiology
- abnormality in spectrin interaction with other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

### Treatment
- immunizations; splenectomy for severe hemolysis

# Glucose-6-Phosphate Dehydrogenase Deficiency

### Definition
- deficiency in glucose-6-phosphate dehydrogenase (G6PD), corresponding to a lack of reduced glutathione (GSH) and leading to RBC sensitivity due to oxidative stress

### Pathophysiology
- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

### Clinical Features
- frequently presents as episodic hemolysis precipitated by:
  - oxidative stress
  - drugs (e.g. sulfonamide, antimalarials, nitrofurantoin)
  - infection
  - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

### Investigations
- neonatal screening
- G6PD assay (may not be useful if result is normal)
  - should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
- blood film
  - Heinz bodies (granules in RBCs due to oxidized Hb); passage through spleen results in the generation of bite cells
  - may have features of intravascular hemolysis (e.g. RBC fragments)

### Treatment
- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases

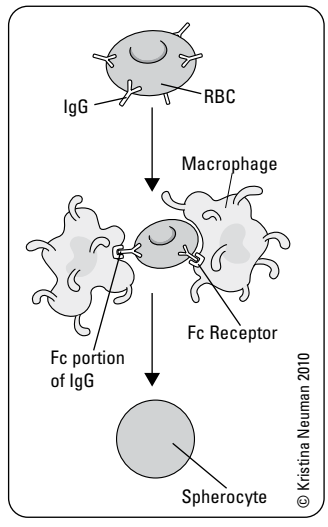

**Figure 10. Spherocytosis secondary to AIHA**

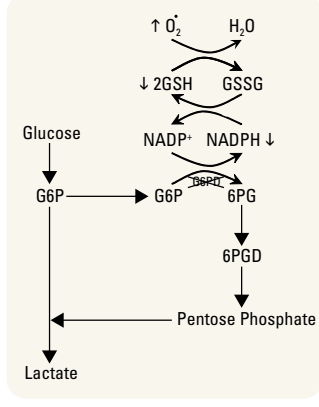

**Figure 11. G6PD deficiency**

# Macrocytic Anemia

- MCV >100 fL
- see Figure 2, *Approach to Anemia*, H6

**Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia**

| | Megaloblastic | Non-Megaloblastic |
|---|---|---|
| **Morphology** | Large, oval, nucleated RBC precursor<br>Hypersegmented neutrophils | Large round RBC<br>Normal neutrophils |
| **Pathophysiology** | Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm | Reflects membrane abnormality with abnormal cholesterol metabolism |

**Causes of Macrocytic Anemia**

**ABCDEF**
**A**lcoholism (liver disease)
**B**$_{12}$ deficiency
**C**ompensatory reticulocytosis
**D**rugs (cytotoxic, AZT)/**D**ysplasia
**E**ndocrine (hypothyroidism)
**F**olate deficiency/**F**etus (pregnancy)

**Characteristics of Megaloblastic Macrocytic Anemia**
- Pancytopenia
- Hypersegmented neutrophils
- Megaloblastic bone marrow

# Vitamin $B_{12}$ Deficiency

- $B_{12}$ (cobalamin)
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

## Etiology

**Table 16. Etiology of Vitamin $B_{12}$ Deficiency**

| Diet | Gastric | Intestinal Absorption | Genetic |
|---|---|---|---|
| **Strict vegan**<br>More likely to present in pediatric population<br>**Vegetarian in pregnancy**<br>**Malnutrition** | **Mucosal atrophy**<br>Gastritis, autoimmune<br>**Pernicious anemia** (see below)<br>**Post-gastrectomy** | **Malabsorption**<br>Crohn's, celiac sprue, pancreatic insufficiency, *H. pylori*<br>**Stagnant bowel**<br>Blind loop, stricture<br>**Fish tapeworm**<br>**Resection of ileum**<br>**Drugs**<br>Neomycin, biguanides, PPI, $N_2O$ anesthesia, metformin | **Transcobalamin II deficiency**<br>**IF receptor defect** |

## Pathophysiology of Pernicious Anemia

- auto-antibodies produced against gastric parietal cells leading to achlorhydria and lack of intrinsic factor secretion
- intrinsic factor is required to stabilize $B_{12}$ as it passes through the bowel
- decreased intrinsic factor leads to decreased ileal absorption of $B_{12}$
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- most common in Northern European Caucasians, usually >30 yr old (median age of 60 yr old)

## Clinical Features

- neurological (severity of anemia and neurological sequelae depends on deficiency)
  - peripheral neuropathy (variable reversibility)
    - usually symmetrical, affecting lower limbs more than upper limbs
  - cord (irreversible damage)
    - subacute combined degeneration
      - posterior columns: decreased vibration sense, proprioception, 2-point discrimination, and paresthesia
      - pyramidal tracts: spastic weakness, ataxia
  - cerebral (common, reversible with $B_{12}$ therapy)
    - confusion, delirium, and dementia
  - cranial nerves (rare)
    - optic atrophy

## Investigations

- CBC, reticulocyte count
  - anemia often severe ± neutropenia ± thrombocytopenia
  - MCV >110 fL
  - low reticulocyte count relative to the degree of anemia (<2%)
- serum $B_{12}$ and RBC folate
  - caution: low serum $B_{12}$ leads to low RBC folate because of failure of folate polyglutamate synthesis in the absence of $B_{12}$
  - alternatively, can measure elevated urine metabolites (methylmalonate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils
- bone marrow
  - hypercellularity
  - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- bilirubin and LDH
  - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- Schilling test (radiolabeled $B_{12}$ test, rarely done) to distinguish pernicious anemia from other causes
  - anti-intrinsic factor antibody, anti-parietal cell antibody

## Treatment

- vitamin $B_{12}$ 1000 µg IM or 1000-1200 µg PO if intestinal absorption intact, route and duration depends on cause
- less frequent, higher doses may be as effective (e.g. 1000 µg IM q3mo)
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

**Oral Vitamin $B_{12}$ vs. Intramuscular Vitamin $B_{12}$ for Vitamin $B_{12}$ Deficiency**
Cochrane DB Syst Rev 2005;3:CD004655
**Study**: Systematic review. 2 RCTs met inclusion criteria; total 108 patients with follow-up from 90 d-4 mo.
**Intervention**: One study evaluated 1000 µg of oral $B_{12}$ compared to 1000 µg IM $B_{12}$ on the same dosing schedule. The other compared 2000 µg daily oral $B_{12}$ to 1000 µg IM $B_{12}$ on a less frequent dosing schedule. Neurological and hematological end points were evaluated.
**Results**: Meta-analysis was not attempted due to study heterogeneity. Both studies reported improvements in hematological and neurological end-points in both oral and IM groups. No significant difference was observed between groups in either study.
**Conclusions**: Limited data suggests high dose oral vitamin $B_{12}$ (1000-2000 µg) is equivalent to IM vitamin $B_{12}$ on the same or less frequent dosing schedule. This data is limited by small sample sizes and short follow-up periods. However, it suggests that a 3 to 4 mo trial of oral supplementation is a reasonable first choice for patients with $B_{12}$ deficiency.

**Schilling Test**

**Part 1**
- Tracer dose (1 µg) of radiolabeled $B_{12}$, given PO
- Flushing dose (1 mg) of unlabeled $B_{12}$ IM 1 h later to saturate tissue binders of $B_{12}$ thus allowing radioactive $B_{12}$ to be excreted in urine
- 24 h urine radiolabeled $B_{12}$ measured
- Normal >5% excretion (a normal excretion will only be seen if the low $B_{12}$ was due to dietary deficiency)

**Part 2**
- Same as part 1, but radiolabeled $B_{12}$ given with oral intrinsic factor
- Should be done only if first stage shows reduced excretion
- Normal test result (>5% excretion) = pernicious anemia
- Abnormal test result (<5% excretion) = intestinal causes (malabsorption)

# Folate Deficiency

- uncommon in developed countries due to extensive dietary supplementation (enriched in flour)
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables and fortified cereals

### Etiology

**Table 17. Etiology of Folate Deficiency**

| Diet/Deficiency | Malabsorption | Drugs | Increased Demand |
|---|---|---|---|
| Alcoholism<br>Substance abuse<br>Elderly/infants<br>Poor intake | Celiac sprue<br>IBD<br>Infiltrative bowel disease<br>Short bowel syndrome | Anti-folates (methotrexate)<br>Anticonvulsants (phenytoin)<br>Alcohol<br>Oral contraceptive | Pregnancy<br>Hemolysis<br>Prematurity<br>Exfoliative dermatitis/psoriasis<br>Hemodialysis |

### Clinical Features
- anemia, mild jaundice, glossitis, diarrhea, confusion, pallor
- consider social history, alcohol/drug abuse, very poor diet (e.g. elderly, depressed)

### Investigations
- similar to $B_{12}$ deficiency (CBC, reticulocytes, blood film, RBC folate, and serum $B_{12}$)
- if decreased RBC folate, rule out $B_{12}$ deficiency as cause

### Management
- folic acid 1-5 mg PO OD x 1-4 mo; then 1 mg PO OD maintenance if cause is not reversible

Never give folate alone to an individual with megaloblastic anemia because it will mask $B_{12}$ deficiency and neurological degeneration will continue

# Hemostasis

## Stages of Hemostasis

### 1. Primary Hemostasis
- cellular defense – involves the platelet and vWF predominantly
- goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
- vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
- blood flow is impeded and platelets come into contact with damaged vessel wall (Figure 12a, H26)
  - activation: platelets are activated resulting in change of shape and release of adenosine diphosphate (ADP) and thromboxane A2
  - adhesion: platelets adhere to subendothelium via von Willebrand factor (vWF)
  - aggregation: these factors further recruit and aggregate more platelets resulting in formation of localized hemostatic plug

### 2. Secondary Hemostasis
- platelet plug is reinforced by production of fibrin clot (Figure 12b, H26)
- extrinsic (initiation) pathway: initiation of coagulation *in vivo*
- intrinsic (amplification) pathway: amplification once coagulation has started via positive feedback
- both intrinsic and extrinsic pathways converge onto the common pathway which results in thrombin generation and fibrin formation

### 3. Fibrin Stabilization
- conversion from soluble to insoluble and stable clot

### 4. Fibrinolysis
- once healing initiated, clot dissolution via action of the fibrinolytic system

**Phases of Hemostasis**

- **Primary hemostasis**
  Vascular response and platelet plug formation via vWF
- **Secondary hemostasis**
  Fibrin clot formation
- **Fibrin stabilization**
  Fibrinolysis

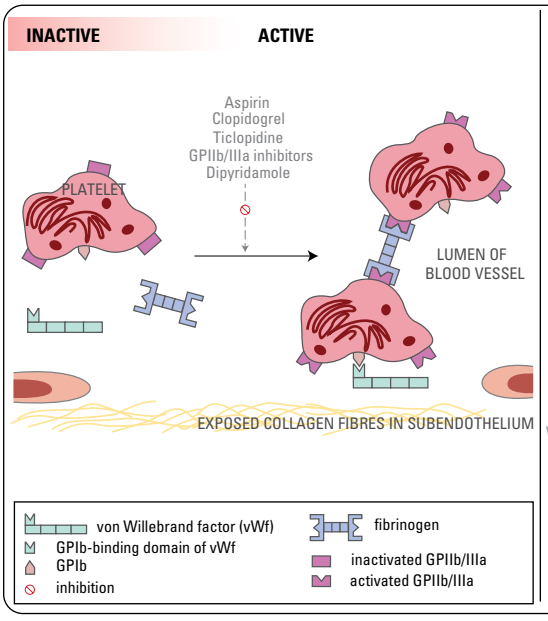

Figure 12a. Platelet activation cascade

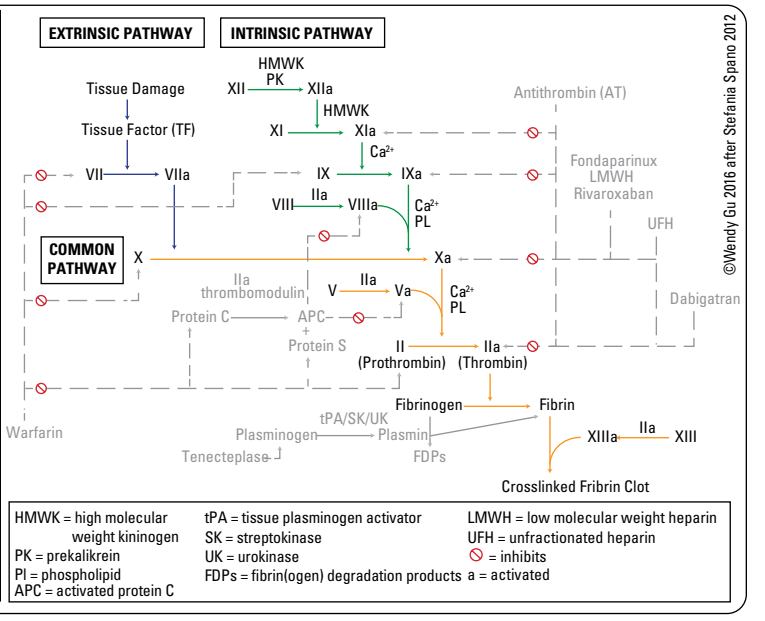

Figure 12b. Coagulation cascade

## Table 18. Commonly Used Tests of Hemostasis

| Type of Hemostasis | Test | Reference Range | Purpose | Examples of Associated Diagnoses |
|---|---|---|---|---|
| **Primary** | Platelet count | 150-400 x $10^9$/L | To quantitate platelet number | Low in ITP, HUS/TTP, DIC, HIT |
| **Secondary** | aPTT | 22-35 s | Measures intrinsic pathway (factors VIII, IX, XI, XII) and common pathway<br>Used to monitor heparin therapy | Prolonged in hemophilias A and B (if factor deficiency is below reagent threshold of detection)<br>N.B. Prolonged if lupus anti-coagulant present |
| | PT | 11-24 s | Measures extrinsic pathway (factor VII) and common pathway | Prolonged in vitamin K deficiency, vitamin K antagonist therapy (warfarin), factor VII deficiency |
| | INR | 0.9-1.2 | Used to monitor warfarin therapy and for assessment of hepatic function | |
| | Mixing studies | | May differentiate inhibitors of clotting factor(s) from a deficiency in clotting factors<br>Mix patient's plasma with normal plasma in 1:1 ratio and repeat abnormal test | Normalization of clotting time if deficiency of single clotting factor (normalization may not occur if multiple clotting factors are deficient)<br>Lack of normalization if inhibitor presence |
| **Fibrinolysis** | Euglobulin lysis time | N >90 min | Looks for accelerated fibrinolysis | May be accelerated in DIC or factor XIII deficiency<br>Decreased in hereditary deficiency of fibrinogen |
| **Other** | Fibrinogen<br>D-dimer<br>Specific factor assays (e.g. factor VIII)<br>Lupus anticoagulant<br>von Willebrand tests (vWF antigen, Ristocetin cofactor activity, factor VIII) | | | |

## Table 19. General Rules of Thumb: Signs and Symptoms of Disorders of Hemostasis

| | Primary (Platelet, vWF) | Secondary (Coagulation) |
|---|---|---|
| **Surface Cuts** | Excessive, prolonged bleeding | Normal/slightly prolonged bleeding |
| **Onset After Injury** | Immediate | Delayed |
| **Site of Bleeding** | Superficial i.e. mucosal (nasal, gingival, GI tract, vaginal), skin | Deep i.e. joints, muscles (excessive, post-traumatic) |
| **Lesions** | Petechiae, ecchymoses | Hemarthroses, hematomas |

**Tests of Secondary Hemostasis**

**PT**/INR: **T**ennis is played outside (Extrinsic pathway)
**PTT**: **T**able **T**ennis is played inside (Intrinsic pathway)

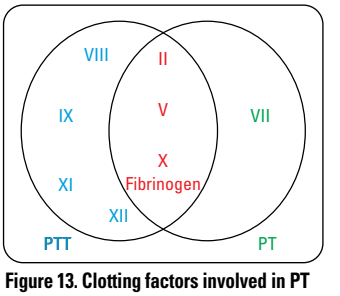

Figure 13. Clotting factors involved in PT and PTT

**Causes of an Prolonged PTT Without Bleeding include:**
1. Early contact factor (Factor XII, HMWK, PK) deficiency
2. Lupus anticoagulant
3. Inappropriate blood draw
4. Heparin contamination
5. Erythrocytosis (laboratory artifact)

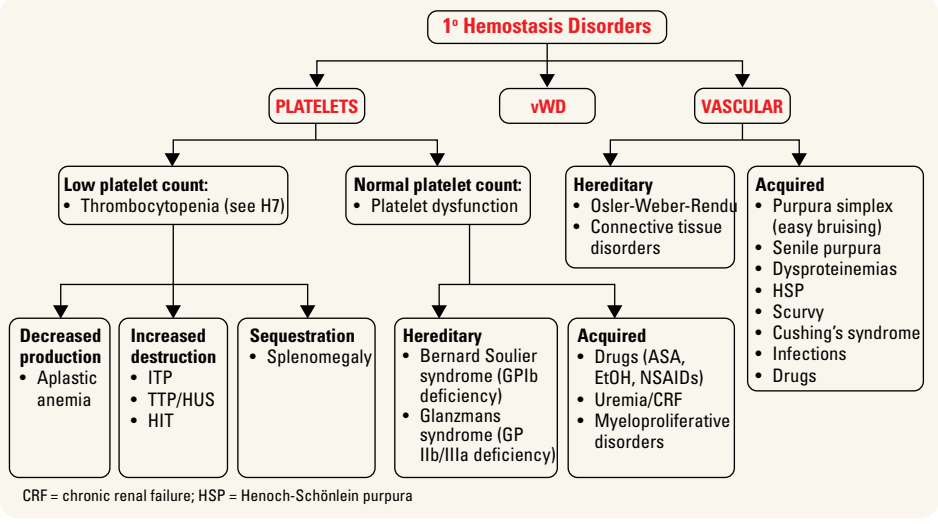
**Consider PTT**
- IV heparin, argatroban monitoring
- Hemophilia A/B, factor XI deficiency, severe vWF

**Table 20. Lab Values in Disorders of Hemostasis**

| | PT | PTT | Platelet Count | Hemoglobin |
|---|---|---|---|---|
| **Hemophilia A/B** | N | ↑ | N | N* |
| **vWD** | N | ± | N/↓ | N* |
| **DIC** | ↑ | ↑ | ↓ | N/↓ |
| **Liver Failure** | ↑ | N/↑ | N/↓ | N |
| **ITP** | N | N | ↓ | N |
| **TTP** | N | N | ↓ | ↓ |

DIC = disseminated intravascular coagulation; ITP = idiopathic thrombocytopenic purpura; TTP = thrombotic thrombocytopenic purpura; vWD = von Willebrand disease;
* = anemia may develop from progressive iron deficiency and/or active bleeding

**Consider PT/INR**
- Warfarin
- Liver disease
- Risk factor for vitamin K deficiency (e.g. malabsorption, cholestasis, malnutrition)



**Consider both PTT and PT/INR**
- Suspected DIC
- Trauma patient, or requiring massive transfusion protocol
- Bleeding patient
- Patient receiving thrombolytic therapy

# Disorders of Primary Hemostasis

## Definition

- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets: abnormal function/numbers
  - disorders of vWF

## Classification

CRF = chronic renal failure; HSP = Henoch-Schönlein purpura

**Figure 14. Approach to disorders of primary hemostasis**

**Drugs Associated with Thrombocytopenia**

| | | |
|---|---|---|
| TMP-SMX | Heparin | NSAIDs |
| Vancomycin | Digoxin | Acetaminophen |
| Rifampin | Amiodarone | Ethanol |
| Ethambutol | Quinidine | $H_2$-antagonists |
| Amphotericin B | Quinine (common) | Chemotherapy |

# Immune Thrombocytopenia

**Table 21. Features for Childhood vs. Adult Immune Thrombocytopenia**

| Features | Childhood ITP, see Pediatrics, P45 | Adult ITP |
|---|---|---|
| **Peak Age** | 2-6 yr | 20-40 yr |
| **Gender** | None | F>M (3:1) |
| **History of Recent Infection** | Common | Rare |
| **Onset of Bleed** | Abrupt | Insidious |
| **Duration** | Usually wk | Mo to yr |
| **Spontaneous Remissions** | 80% or more | Uncommon |

## Terminology of ITP

- also known as immune thrombocytopenia
- primary: isolated thrombocytopenia (platelet count <100 x $10^9$/L) with no other cause of thrombocytopenia
- secondary: thrombocytopenia associated with another condition (e.g. HIV, HCV, SLE, CLL)
- drug-induced: drug-dependent platelet antibodies causing platelet destruction

### Classification of Primary ITP
- acute: newly diagnosed (diagnosis to 3 mo)
- persistent: 3-12 mo from diagnosis
- chronic: >12 mo
- refractory: post-splenectomy

### Pathophysiology
- primary or secondary ITP
- an acquired immune-mediated disorder (pathophysiology incompletely understood)
  - anti-platelet antibodies bind to platelet surface → increased splenic clearance
  - impaired platelet production
  - helper T-cell and cytotoxic T-cell activation also implicated in platelet destruction

### Clinical Feature
- variable presentation: asymptomatic, fatigue, minimal bruising, mucocutaneous bleed (e.g. purpura, ecchymoses, petechiae, continuous epistaxis, menorrhagia), and intracranial bleed
- assess for symptoms/signs suggesting a secondary cause

### Investigations
- CBC and reticulocyte count: thrombocytopenia
- PT and aPTT: normal
- peripheral blood film: decreased platelets, giant platelets (rule out platelet clumping)
- HIV, HCV, *H. pylori* serology
- vitamin $B_{12}$, ANA, C3, C4, depending on clinical symptoms
- bone marrow aspirate and biopsy: increased number of megakaryocytes
  - recommended in patients >60 yr of age, pre-splenectomy or have failed traditional ITP therapy, those with systemic symptoms, an abnormal blood film
  - bone marrow aspirate and biopsy should be considered if there is any suspicion of diminished bone marrow function (e.g. myelodysplasia, infiltration)

### Treatment
- rarely indicated if platelets >30 x $10^9$/L unless active bleeding, trauma, or surgery
- emergency treatment (active bleeding [CNS, GI, or GU] or in need of emergency surgery)
  - general measures: stop drugs that reduce platelet function, control blood pressure, minimize trauma
  - corticosteroids: prednisone (1 mg/kg/d) or dexamethasone (40 mg PO/d x 4 d)
  - antifibrinolytic: tranexamic acid (1 g PO tid or 1 g IV q6h) if mucosal bleeding
  - IVIg 1 g/kg/d x 2 doses (raises platelet count faster than corticosteroids)
  - platelet transfusion: for refractory, major bleeding or need for urgent surgery (expect that platelet recovery will be diminished)
  - emergency splenectomy: may be considered, vaccinations prior if possible (pneumococcus, meningococcus, H. influenzae b)
  - management of intracranial bleeding: IV steroids, IVIg, platelets
- non-urgent treatment (platelet count <20-30 x $10^9$/L and no bleeding)
  - 1st-line
    - corticosteroids (dexamethasone 40 mg PO qd x 4 d x 1-4 cycles (not wk) or prednisone x 3 wk then slow taper)
    - IVIg
    - anti-D: appropriate for Rh+ non-splenectomized patients, but can cause hemolysis (avoid if low Hb at baseline or if DAT is positive)
  - 2nd-line
    - splenectomy (need vaccinations prior to splenectomy: pneumococcus, meningococcus, and *H. influenzae* b)
    - rituximab
  - 3rd-line
    - thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag) – may be considered for 2nd-line therapy if funding available
    - immunomodulating therapy (azathioprine, cyclophosphamide, danazol, and vincristine)

### Definitions of Response to Treatment
- complete response: platelet >100
- partial response: platelet 30-100
- no response: platelet <30

### Prognosis
- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- overall relatively benign, life-expectancy similar to general population (however, risk of mortality from bleeding/infection increases with advancing age)
- major concern is spontaneous intracranial hemorrhage if platelet <5 x $10^9$/L, more common in the elderly

**Mechanisms for HIV-associated Thrombocytopenia**
- Direct effect of HIV on marrow
- Immune-mediated platelet destruction
- Some anti-retrovirals reduce platelet production

## Table 22. Heparin-Induced Thrombocytopenia (HIT)

| | |
|---|---|
| **Pathophysiology** | Immune mediated<br>Ab recognizes a complex of heparin and platelet factor 4 (PF4) leading to platelet activation via platelet Fc receptor and activation of coagulation system |
| **Diagnosis** | Suspected with intermediate or high probability HIT Score<br>Confirm with ELISA testing and Serotonin Release Assay testing |
| **Onset of Decreased Platelets** | 5-15 d (if previously exposed to heparin within 100 d, HIT can develop in hours due to an anamnestic response) |
| **Risk of Thrombosis** | ~30% to 50% (25% of events are arterial) |
| **Clinical Features** | Bleeding complications uncommon<br>Venous thrombosis: DVT, PE, limb gangrene, cerebral sinus thrombosis<br>Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney)<br>Heparin-induced skin necrosis (with LMWH)<br>Acute platelet activation syndromes: acute inflammatory reactions (e.g. fever/chills, flushing, etc.)<br>Transient global amnesia (rare) |
| **Specific Tests** | Pre-test clinical scoring models can help rule-out HIT: 4-Ts and the HIT Expert Probability (HEP) score<br>14C serotonin release assay (tests the functional ability of patient's plasma to activate platelets)<br>ELISA for HIT-Ig (more sensitive, less specific than serotonin assay, faster turnaround time, high negative predictive value)<br>Ultrasound of lower limb veins for DVT |
| **Management** | Clinical suspicion of HIT should prompt discontinuation of heparin and LMWH (specific tests take several days)<br>Initiate anticoagulation with a non-heparin anticoagulant:<br>e.g. argatroban, danaparoid, fondaparinux, bivalirudin unless there is a strong contraindication (duration of treatment at least 2-3 mo if no thrombotic event, and at least 3-6 mo if thrombotic event has occurred)<br>Warfarin should only be restarted when platelet count >150 x $10^9$/L<br>Allergy band and alert in patient records |

## Table 23. The 4-T Pre-Test Clinical Scoring Model for HIT

| Category | 2 Points | 1 Point | 0 Points |
|---|---|---|---|
| **1. Thrombocytopenia** | Platelet count fall >50%<br>AND<br>platelet nadir ≥20 x $10^9$/L | Platelet count fall 30-50%<br>OR<br>platelet nadir 10-19 x $10^9$/L | Platelet count fall <30%<br>OR<br>platelet nadir <10 x $10^9$/L |
| **2. Timing of Platelet Count Fall** | Clear onset between 5-10 d of heparin exposure<br>OR<br>platelet count fall at ≤1 d if prior heparin exposure within last 30 d | Consistent with fall in platelet count at 5-10 d but unclear (e.g. missing platelet counts)<br>OR<br>onset after day 10<br>OR<br>fall ≤1 d with prior heparin exposure within 30-100 d | Platelet count fall after <4 d of heparin exposure, and no recent heparin |
| **3. Thrombosis or Other Sequelae** | Confirmed new thrombosis, skin necrosis, or acute systemic reaction after IV unfractionated heparin bolus | Progressive or recurrent thrombosis, non-necrotizing (erythematous) skin lesions, or suspected thrombosis that has not been proven | None |
| **4. Other Causes for Thrombocytopenia** | None apparent | Possible | Definite |

6-8 points = high probability of HIT; 4-5 points = intermediate probability of HIT; 0-3 points = low probability of HIT
*J Thromb Haemos* 2006;4:759-765

**Heparin-Induced Thrombocytopenia**
- Heparin-induced thrombocytopenia (previously known as HIT type II): immune-mediated reaction following treatment with heparin leading to platelet and subsequent coagulation activation
- Heparin-associated thrombocytopenia (previously known as HIT type I): transient thrombocytopenia following administration of heparin

**Heparin-Associated Thrombocytopenia (previously known as HIT type I)**
- Direct heparin mediated platelet aggregation (non-immune)
- Platelets >100 X $10^9$/L
- Self-limited (no thrombotic risk)
- May continue with heparin therapy
- Onset 24-72 h

LMWH is also associated with HIT, but the risk is less than unfractionated heparin (2.6% in UFH vs. 0.2% in LMWH)

**American Society of Hematology Choosing Wisely Recommendation**
Don't test or treat for HIT in patients with low pre-test probability of HIT (4T's score of 0-3) as HIT can be excluded
Do not discontinue heparin or start a non-heparin anticoagulant in these low-risk patients because of increased risk of bleeding and increased cost of alternatives

# Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome

**Table 24. TTP and HUS**

| | TTP | HUS (see Pediatrics, P73) |
|---|---|---|
| **Epidemiology** | Predominantly adult | Predominantly children and elderly |
| **Etiology** | Deficiency of metalloproteinase that breaks down ultra-large vWF multimers: ADAMTS13<br>Congenital (genetic absence of ADAMTS-13)<br>Acquired (drugs, malignancy, transplant, and HIV-associated, idiopathic) | Shiga toxin (*E. coli* serotype O157:H7) in 90%<br>Other bacteria, viruses, genetic causes, and drugs |
| **Clinical Features** | 1. Thrombocytopenia<br>2. MAHA/TMA<br>3. Neurological symptoms: headache, confusion, focal defects, and seizures<br>4. Symptoms can be mild and non-specific | 1. Severe thrombocytopenia<br>2. MAHA/TMA<br>3. Acute kidney injury<br>4. Bloody Diarrhea<br>5. GI prodrome |
| **Investigations (both TTP, HUS)** | CBC and blood film: decreased platelets and increased schistocytes<br>PT, aPTT, fibrinogen: normal<br>Markers of hemolysis: increased unconjugated bilirubin, increased LDH, and decreased haptoglobin<br>Negative Coombs test<br>Creatinine and urea to follow renal function (TTP has nearly no kidney injury vs. HUS/drug mediated TTP which induces severe injury that is sudden in onset)<br>ADAMSTS-13 gene, activity or inhibitor testing (TTP) | |
| **Management** | Medical emergency<br>Plasma exchange ± steroids<br>Platelet transfusion avoided unless life-threatening bleed (associated with microvascular thrombosis)<br>Plasma infusion if plasmapheresis is not immediately available<br>*Caplacizumab in certain cases of acquired TTP<br>TTP mortality ~90% if untreated | Supportive therapy (fluids, RBC transfusion, nutrition, etc.)<br>Some evidence for plasma exchange<br>Possible role of Eculizumab (C5 antibody blocks complement activation) for neurologic symptoms |

Note: atypical HUS is a complex disease with different etiology, treatment depends on genetic abnormalities

**Pathophysiology of TTP**
- Large vWF multimers secreted by endothelial cells are typically rapidly cleaved by ADAMTS-13 protease
- Congenital TTP is due to a genetic deficiency in ADAMTS-13
- Acquired TTP (the more common form) antibodies against ADAMTS-13 are present

**Differential Diagnosis of TTP**
- DIC
- HUS
- aHUS
- HELLP
- Catastrophic antiphospholipid Ab syndrome
- Evans syndrome (AIHA + ITP)

# von Willebrand Disease

## Pathophysiology
- most common inherited bleeding disorder (prevalence of 1%)
- usually autosomal dominant (type 3 is autosomal recessive)
- women more commonly diagnosed (heavy menstrual bleeding, peripartum bleeding)
- qualitative defect or quantitative deficiency of vWF depending on type
  - vWF needed for platelet adhesion/aggregation and acts as chaperone for Factor VIII (extending its half-life in circulation), therefore abnormality of vWF can affect both primary and secondary hemostasis
  - vWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion/aggregation
    - both large and small multimers complex with Factor VIII
    - vWF levels vary according to blood group (non-group O patients have higher levels than group O patients)

## Classification
- type 1: mild quantitative defect (decreased amount of vWF and proportional decrease in vWF activity) – 80% of cases
- type 2: qualitative defect (vWF activity disproportionally lower than quantity) – 20% of cases
- type 3: severe total quantitative defect (virtually no vWF produced) – 1 per million

## Clinical Features
- bleeding history is the single most important predictor of an underlying bleeding disorder
- validated, standardized bleeding assessment tools (e.g. ISTH-BAT) to facilitate exploration of the bleeding history
- mucocutaneous bleeding (easy bruising, epistaxis (>10 min), heavy menstrual bleeding, peripartum bleeding, post-dental extraction bleeding, excessive post-operative bleeding, and unexplained gastrointestinal bleeding)
  - type 3 vWF patients can experience musculoskeletal bleeding due to significant deficiency in FVIII due to lack of FVIII chaperoning as vWF is absent
- family history of a bleeding disorder

## Investigations
- CBC, platelet, vWF:Antigen (determine how much vWF is present), vWF:Ristocetin cofactor activity (determine how well vWF binds to platelet), Factor VIII (determine how well vWF chaperones with FVIII), and PTT
- tests to further categorize type/subtype of vWD: multimer analysis, ristocetin induced platelet agglutination, and genetic studies

**Table 25. Investigations in vWD**

| Test | Expected Result | Test | Expected Result |
|---|---|---|---|
| PTT | N/↑ | von Willebrand antigen | ↓ |
| Factor VIII | N/↓ | Blood group | Affects antigen quantification (↓ in group O) |
| Plt Count | N/↓ | vWF multimer analysis | Multimer variants |
| Ristocetin Activity | ↓ (cofactor for vWF-Plt binding) | | |

### Treatment
- desmopressin (DDAVP®) is effective treatment for 85-90% of patients with type 1 vWD and for some subtypes of type 2 vWD
  - causes release of vWF and Factor VIII from endothelial cells
  - variable efficacy depending on disease type; tachyphylaxis occurs after 4 consecutive doses
  - need to document responsiveness with "DDAVP® challenge"
  - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron®, antifibrinolytic) to stabilize clot formation
- vWF:FVIII concentrate (Humate P®, Wilate®) if DDAVP® unresponsive/clinically ineffective or for severe bleeding episode
  - need to monitor vWF and factor VIII levels (very high factor VIII level can be prothrombotic)
- gynecologic focused care for heavy menstrual bleeding (NB estrogens have the added benefit of increasing vWF levels)

### Prognosis
- patients with mild type 1 vWD have auto-correction of vWF deficiency in pregnancy
- most cases are mild-moderate, and only ~10% of cases require long-term prophylactic therapy

Consider vWD in all women with menorrhagia

vWD is the most common inheritable couagulation abnormality

# Disorders of Secondary Hemostasis

### Definition
- inability to form an adequate fibrin clot
  - disorders of clotting factors or co-factors
  - disorders of proteins associated with fibrinolysis
- characterized by delayed bleeding, deep muscular bleeding, and spontaneous hemarthroses

**Table 26. Classification of Secondary Hemostasis Disorders**

| Hereditary | Acquired |
|---|---|
| Factor VIII: Hemophilia A, vWD | Liver disease |
| Factor IX: Hemophilia B (Christmas Disease) | DIC |
| Factor XI | Vitamin K deficiency |
| Other factor deficiencies are rare | Acquired inhibitors (FVIII most common) |

## Hemophilia A (Factor VIII Deficiency)

### Pathophysiology
- X-linked recessive, 1/5000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

### Clinical Features
- see Table 19 – *Signs and Symptoms of Disorders of Hemostasis*, H26
- older patients may also acquired HIV or HCV from contaminated blood products

### Investigations
- prolonged aPTT, normal INR (PT)
- decreased Factor VIII (<40% of normal)

### Treatment
- desmopressin (DDAVP®) in mild hemophilia A
- Factor VIII concentrate for:
  - prophylaxis
  - on-demand (i.e. to treat a bleed)
- anti-fibrinolytic agents (e.g. tranexamic acid)

## Hemophilia B (Factor IX Deficiency)

- X-linked recessive, 1/30,000 males; approximately half have severe disease (factor IX activity <1% of normal)
- clinical and laboratory features identical to hemophilia A (except decreased Factor IX)
- treatment: Factor IX concentrate (prophylaxis or on-demand), anti-fibrinolytic agents

# Factor XI Deficiency

- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild, often diagnosed in adulthood
- Factor XI level does not correlate with bleeding risk – risk of bleeding correlates with a previous history or family history of bleeding
- treatment: antifibrinolytic agents, frozen plasma, and Factor XI concentrate

# Liver Disease

- see Gastroenterology, G31

### Pathophysiology
- deficient synthesis of all factors except VIII (also made in endothelium)
- aberrant or diminished synthesis of fibrinogen (factor I)
- diminished synthesis of natural anticoagulants and altered regulation of fibrinolysis

### Investigations
- peripheral blood film: target cells
- primary hemostasis affected
  - thrombocytopenia 2º to hypersplenism, nutritional deficiency, direct bone marrow toxicity related to alcohol, diminished production from chronic viral infections (e.g. HCV), and decreased production of thrombopoietin
- secondary hemostasis affected
  - elevated INR (PT), aPTT, TT (thrombin time)
  - low fibrinogen in end-stage liver disease

**Investigations in Liver Disease**
Factor V, VII, VIII. Expect decreased V and VII because they have the shortest half-life. Factor VIII will be normal or increased because it is produced in the endothelium

### Treatment
- supportive, treat liver disease, blood products if active bleeding (frozen plasma, platelets, cryoprecipitate)

# Vitamin K Deficiency

### Etiology
- drugs
  - vitamin K antagonist (e.g. Warfarin) – diminished production of functional Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet (especially in alcoholics) e.g. prolonged fasting or starvation
- biliary obstruction
- chronic liver disease (decreased stores)
- fat malabsorption (e.g. celiac disease, disorders of bile or pancreatic secretion, and intestinal disease, CF)
- hemorrhagic disease of newborn, see Pediatrics, P64

**Vitamin K Dependent Factors**
Vitamin K antagonists (e.g. warfarin) affect function of these factors:
"1972 Canada vs. Soviets"
X, IX, VII, II proteins C and S

### Investigations
- INR (PT) is elevated out of proportion to elevation of the aPTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

PT should improve within 24 h of adequately dosed vitamin K repletion (onset is in 6-12 h); if not, search for other causes

### Treatment
- hold anticoagulant if vitamin K antagonist on board
- vitamin K PO if no active bleeding
- if bleeding, give vitamin K 10 mg IV (reversal may take up to 12 h)
- if life-threatening bleeding and vitamin K antagonist used, give prothrombin complex concentrate (PCC) or FP if PCC contraindicated
  - PCCs are contraindicated in liver disease and if there is a previous history of HIT (PCC product contains heparin)

**American Society of Hematology Choosing Wisely Recommendation**
Do not administer plasma or prothrombin complex concentrates for non-emergent reversal of vitamin K antagonists (e.g. outside of the setting of major bleeding, intracranial hemorrhage, or anticipated emergent surgery)

# Disseminated Intravascular Coagulation

### Definition
- excessive, dysregulated release of plasmin and thrombin leading to intravascular coagulation and depletion of platelets, coagulation factors and fibrinogen
- risk of life-threatening hemorrhage or thromboembolism

### Etiology
- occurs as a complication of many other severe medical, surgical or obstetrical conditions
- widespread endothelial damage and extensive inflammatory cytokine release

DIC is a spectrum which may include thrombosis, bleeding, or both

**Factor Levels in Acquired Coagulopathies**

| Factor | Liver Disease | Vitamin K Def | DIC |
|---|---|---|---|
| V | ↓ | N | ↓ |
| VII | ↓ | ↓ | ↓ |
| VIII | N/↑ | N | ↓ |

**Table 27. Etiology of DIC**

| Activation of Procoagulant Activity | Endothelial Injury | Reticuloendothelial Injury | Vascular Stasis | Other |
|---|---|---|---|---|
| Antiphospholipid antibody syndrome (APS)<br>Intravascular hemolysis<br>Incompatible blood, malaria<br>Tissue injury<br>Obstetric complications, trauma, burns, crush injuries<br>Malignancy<br>Solid tumours, hematologic malignancies (especially APML)<br>Snake venom, fat embolism, heat stroke | Infections/sepsis<br>Vasculitis<br>Metastatic adenocarcinoma<br>Aortic aneurysm<br>Giant hemangioma | Liver disease<br>Splenectomy | Hypotension<br>Hypovolemia<br>Pulmonary embolus | Acute hypoxia/ acidosis (check lactate) |

**Important Etiologies of DIC**

**OMITS**
**O**bstetric complications
**M**alignancy
**I**nfection
**T**rauma
**S**hock

## Clinical Features

- presence of both hemorrhage and clotting

**Table 28. Clinical Features of DIC**

| Signs of Microvascular Thrombosis | Signs of Hemorrhagic Diathesis |
|---|---|
| **Neurological:** multifocal infarcts, delirium, coma, seizures<br>**Skin:** focal ischemia, superficial gangrene<br>**Renal:** oliguria, azotemia, cortical necrosis<br>**Pulmonary:** ARDS<br>**GI:** acute ulceration<br>**RBC:** microangiopathic hemolysis | Bleeding from any site in the body (2º to decreased platelets and clotting factors)<br>**Neurologic:** intracranial bleeding<br>**Skin:** petechiae, ecchymosis, oozing from puncture sites<br>**Renal:** hematuria<br>**Mucosal:** gingival oozing, epistaxis, massive bleeding |

**Clinical Prediction of DIC - International Society of Thrombosis and Hemostasis (ISTH) Calculator**

Presence of an underlying, predisposing condition is a requirement
Platelet count:
- 50-100 = 1 point
- <50 = 2 points

Fibrin-related marker (D-dimer or FDP):
- moderate increase = 2 points
- marked increase = 3 points

Fibrinogen (g/L):
- <1 = 1 point

PT:
- 3 - 6 s = 1 point
- >6 s = 2 points

DIC diagnosis is defined as ≥ 5 points

## Investigations

- primary hemostasis: decreased platelets
- secondary hemostasis: prolonged INR (PT), aPTT, TT, decreased fibrinogen and other factors
- fibrinolysis: increased FDPs or D-dimers and short euglobulin lysis time (i.e. accelerated fibrinolysis)
- extent of fibrin deposition: urine output and RBC fragmentation

## Treatment

- recognize early and treat underlying disorder – supportive measures: hemodynamic and/or ventilator support, aggressive hydration, and RBC transfusion if severe bleed
- in hemorrhage: replacement of hemostatic elements with platelet transfusion, frozen plasma, and cryoprecipitate
  - British Hematology Guidelines:
    - maintain platelets >50 x $10^9$/L, hemoglobin >80 g/L, calcium between 2.2-2.7 mmol/L, and avoid hypothermia
    - 4-5 units of FP if INR >1.5 or aPTT >38
    - 10 units of cryoprecipitate if fibrinogen <1 g/L
    - 1 adult dose of buffy-coat platelets if <10 x $10^9$/L (<20 if febrile, <50 before invasive procedure)
- in thrombotic phase: UFH or LMWH in critically ill, non-bleeding patients

**Table 29. Screening Test Abnormalities in Coagulopathies**

| Increased INR Only | Increased PTT Only | Both Increased |
|---|---|---|
| Warfarin<br>Vitamin K deficiency<br>Factor VII deficiency<br>Liver disease<br>Factor VII inhibitors | Hemophilia A and B<br>Heparin<br>Antiphospholipid Ab<br>Intrinsic factor inhibitors (e.g. FVIII)<br>Factor XI and XII deficiency | Prothrombin deficiency<br>Severe fibrinogen deficiency<br>Factor V and X deficiency<br>Severe liver disease<br>Factor V and X, prothrombin, and fibrinogen inhibitors<br>Excessive anticoagulation<br>Severe vitamin K deficiency |

**Differential Diagnosis of Elevated D-Dimer**

- Arterial thromboembolic disease (MI, cerebrovascular accident, acute limb ischemia, AFib, intracardiac thrombus)
- Venous thromboembolic disease (DVT, PE)
- DIC
- Preeclampsia and eclampsia
- Abnormal fibrinolysis; use of thrombolytic agents
- Cardiovascular disease, CHF
- Severe infection/sepsis/inflammation
- Surgery/trauma (tissue ischemia, necrosis)
- Systemic inflammatory response syndrome
- Vasoocclusive episode of sickle cell disease
- Severe liver disease
- Malignancy
- Renal disease (nephrotic syndrome, acute/chronic renal failure)
- Normal pregnancy
- Venous malformation

# Hypercoagulable Disorders

## Hypercoagulability Workup – Venous Thrombosis

- workup for hypercoagulable state is controversial and should only be done if it will alter treatment decisions
  - recommendations for a hypercoagulable workup include:
    - patients with recurrent or multiple thrombosis only if it will change management plans
    - warfarin-induced skin necrosis or neonatal purpura fulminans (protein C or S deficiency)
    - consider for patients with a family history of VTE who are considering OCP use
    - consider for patients who present with thrombosis at an unusual venous site only if it will change management plans
    - workup for malignancy is suggested in the event of abnormal blood work, constitutional symptoms or physical exam suggestive of cancer
  - arterial thrombotic events due to a hypercoagulable state are typically associated with APLA, HIT, JAK2 MPNs, and PNH, not hereditary thrombophilias

**American Society of Hematology Choosing Wisely Recommendations**

1. Do not test for thrombophilia in adult patients with venous thromboembolism occurring in the setting of major transient risk factors (surgery, trauma, or prolonged immobility)
2. Do not use inferior vena cava filters routinely in patients with acute venous thromboembolism

- workup
  - initial
    - CBC, blood smear, coagulation studies, liver/renal function, urinalysis, and hemolysis markers (if anemic)
    - malignancy history, age appropriate cancer screening
    - serology: APLA
  - post-treatment (or ≥6 wk, as protein levels depleted/consumed by clot)
    - antithrombin (not on heparin)
    - proteins C, S (not on warfarin)
- note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state
  - thus, more focus on the reversible/treatable causes (APLA, cancer, etc.)

## SELECTED CAUSES OF HYPERCOAGULABILITY

### Activated Protein C Resistance (Factor V Leiden)
- most common cause of hereditary thrombophilia
- 3-7% of European Caucasian population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

### Prothrombin Gene Mutation (PT) G20210A
- 1-3% of European Caucasian population are heterozygotes
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

### Protein C and Protein S Deficiency
- protein C inactivates Factor Va and VIIIa using protein S as a cofactor
- protein C deficiency
  - homozygous or compound heterozygous: neonatal purpura fulminans
  - heterozygous
    - type I: decreased protein C levels
    - type II: decreased protein C activity
  - acquired: liver disease, sepsis, DIC, warfarin, and certain chemotherapeutic agents
  - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, and warfarin

### Antithrombin Deficiency
- antithrombin slowly inactivates thrombin in the absence of heparin, rapidly inactivates thrombin in the presence of heparin
- autosomal dominant inheritance, urinary losses in nephrotic syndrome, or reduced synthesis in liver disease
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to unfractionated heparin (LMWH may be considered, with monitoring of anti-Xa levels)
  - heparin resistance: suspect if >35,000 units of UFH required during 24 h use

### Elevated Factor VIII Levels
- an independent marker of increased incident and recurrent thrombotic risk, but levels can also be increased in numerous states as an acute phase reactant, therefore its clinical use is controversial

### Congenital Dysfibrinogenemia
- may predispose to thromboembolic disease, bleeding or both

### Disorders of Fibrinolysis
- includes congenital plasminogen deficiency, tissue plasminogen activator deficiency, although association with VTE risk is not clear

### Antiphospholipid Antibody Syndrome (APS)
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: arterial or venous thrombosis, recurrent (>3) early pregnancy losses <10 wk, one late fetal loss ≥10 wk (morphologically normal), or premature birth before 34 wk due to (pre)eclampsia or placental insufficiency
  - laboratory (must be confirmed on two occasions, tested ≥12 wk apart): anticardiolipin antibodies, anti-β2 glycoprotein-I antibody, or lupus anticoagulant
- mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased activation; can also interfere with thrombin regulation, fibrinolysis, and inhibit the protein C pathway
- see Rheumatology, RH13

**Common Causes of Hypercoagulability**

**CALM APES**
Protein **C** deficiency
**A**ntiphospholipid **A**b
Factor V **L**eiden
**M**alignancy
**A**ntithrombin deficiency
**P**rothrombin G20210A
Increased Factor **VIII** (**E**ight)
Protein **S** deficiency

**Causes of Both Venous and Arterial Thrombosis include:**
- Antiphospholipid antibodies
- Myeloproliferative neoplasms
- Heparin-induced thrombocytopenia
- Distal venous clot with patent foramen ovale
- Paroxysmal nocturnal hemoglobinuria

Protein C, protein S, and ATIII are decreased during acute thrombosis – therefore to test for deficiency, must be tested outside of this time period

**Malignancy is a common cause of acquired hypercoagulability**
**Workup should include:**
- Complete history and physical
- Routine blood work
- Urinalysis
- CXR
- Age appropriate screening: mammogram, Pap, PSA, colonoscopy
- Close follow-up
- No benefit with CT imaging

Although lupus anticoagulant prolongs PTT, this is a misnomer, as its main clinical feature is thrombosis

# Venous Thromboembolism

## Definition
- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- superficial thrombophlebitis, deep vein thrombosis (DVT), and pulmonary embolism (PE)
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- more common in lower extremity than upper extremity
- incidence ~1% if age >60 yr
- most important sequelae are pulmonary embolism (~50% chance with proximal DVT) and chronic venous insufficiency

## Etiology (Virchow's Triad)
- endothelial damage
  - exposes endothelium to prompt hemostasis
  - leads to decreased inhibition of coagulation and local fibrinolysis
- venous stasis
  - immobilization (post-MI, CHF, stroke, and post-operative) inhibits clearance and dilution of coagulation factors
- hypercoagulability
  - inherited (see *Hypercoagulable Disorders*, H33)
  - acquired
    - age (risk increases with age)
    - surgery (especially orthopedic, thoracic, GI, and GU)
    - trauma (especially fractures of spine, pelvis, femur or tibia, and spinal cord injury)
    - neoplasms (especially lung, pancreas, colon, rectum, kidney, and prostate)
    - blood dyscrasias (myeloproliferative neoplasms, especially PV, ET), PNH, and hyperviscosity (multiple myeloma, polycythemia, leukemia, and sickle cell disease)
    - prolonged immobilization (CHF, stroke, MI, and leg injury)
    - hormone related (OCP, HRT, and SERMs)
    - pregnancy
    - APS
    - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
- idiopathic (10-20% are later found to have cancer)

## Clinical Features of DVT
- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness; purple-blue colour
- palpable cord (thrombosed vein)
- phlegmasia alba dolens (white appearance) and phlegmasia cerula dolens (acute pain and edema) with massive thrombosis
- Homan's sign (pain with foot dorsiflexion) is unreliable

## Differential Diagnosis of DVT
- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, and arterial occlusive disease

## Investigations for DVT
- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease and no other acute medical issues
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~95%
  - sensitivity for calf DVT ~70%
- other non-invasive tests include MRI and impedence plethysmography
- venography is the gold standard, but is expensive, invasive, and higher risk
- CTPA or V/Q scan if PE suspected

## Post-Thrombotic Syndrome
- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, and venous ulcers
- clinical severity can be estimated based on the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, continuous compression stockings, intermittent pneumatic compression therapy, and skin/ulcer care
- for clinical features and treatment of PE, see Respirology, R19

**Risk of VTE in Hospitalized Patients Receiving Ineffective Antithrombotic Therapy**

| Risk Factor | RR (95% CI) | P-value |
|---|---|---|
| Age >75 yr | 1.79 (1.18-2.71) | 0.007 |
| Cancer | 1.58 (1.01-2.51) | |
| Previous VTE | 1.67 (1.01-2.77) | 0.08 |
| Obesity | 0.94 (0.59-1.51) | 0.91 |
| Hormone therapy | 0.51 (0.08-3.38) | 0.70 |
| Heart failure | 0.08 (0.72-1.62) | 0.82 |
| NYHA III | 0.89 (0.55-1.43) | 0.72 |
| NYHA IV | 1.48 (0.84-2.6) | 0.27 |
| Acute infectious disease | 1.50 (1.00-2.26) | 0.06 |
| Acute rheumatic disease | 1.45 (0.84-2.50) | 0.27 |

Source: *JAMA* 2004;164:963-968

**Virchow's Triad**
- Endothelial damage
- Stasis
- Hypercoagulability

**Wells' Score for DVT Criteria (Score)**
- Paralysis, paresis, or recent orthopedic casting of lower extremity (1)
- Recently bedridden (>3 d) or major surgery within past 4 wk (1)
- Localized tenderness in deep vein system (1)
- Swelling of entire leg (1)
- Calf swelling >3 cm than other leg (measured 10 cm below the tibial tuberosity) (1)
- Pitting edema greater in the symptomatic leg (1)
- Collateral non-varicose superficial veins (1)
- Active cancer or cancer treated within 6 mo (1)
- Alternative diagnosis more likely than DVT (e.g. Baker's cyst, cellulitis, muscle damage, superficial venous thrombosis) (-2)

**Total Score Interpretation**
3-8: High probability, 1-2: Moderate probability, -2-0: Low probability

**Modified Wells Score**
Same as above except with 1 additional point for a history of DVT or major surgery within past 12 wk, and the score interpretation is DVT likely for ≥ 2 points and DVT unlikely for ≤1 point. D-dimer is ordered for DVT unlikely patients to fully rule out DVT which can help reduce unnecessary ultrasounds

**Low-Molecular-Weight Heparin vs. Coumadin® for the Prevention of Recurrent Venous Thromboembolism in Patients with Cancer**
NEJM 2003;349:146-153
**Study**: RCT comparing the efficacy of LMWH (dalteparin) with an oral anti-coagulant agent (coumarin) in preventing recurrent thrombosis in patients with cancer.
**Methods**: Patients with cancer who had acute, symptomatic proximal DVT, PE, or both were randomly assigned to either dalteparin or coumarin treatment for 6 mo.
**Results**: 27 of 336 patients in the dalteparin group had recurrent VTE versus 53 of 336 patients in the coumarin group (hazard ratio, 0.48; p=0.002). The probability of recurrent thromboembolism at 6 mo was 9% and 17% in dalteparin and coumarin groups respectively. There was no significant difference in bleeding rates. The mortality rate was 39% in the dalteparin group and 41% in the coumarin group.
**Conclusions**: In patients with cancer and acute VTE, dalteparin was more effective than coumarin in decreasing the risk of recurrent thromboembolism without increasing the risk of bleeding.

# Approach to Treatment of Venous Thromboembolism

## Purpose

- prevent further clot extension (3 mo duration is optimal)
- prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- treatment of massive ileofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- limit development of late complications (e.g. postphlebitic syndrome, chronic venous insufficiency, and chronic thromboembolic pulmonary HTN)

## Initial Treatment

- low molecular weight heparin (LMWH)
  - administered SC, at least as effective as UFH with a lower bleeding risk
  - advantages: predictable dose response and fixed dosing schedule; lab monitoring not required; <1% HIT; safe and effective outpatient therapy
  - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis, costly!
  - renally cleared – must adjust dose in patients with renal dysfunction
- unfractionated heparin (UFH)
  - in patient with average risk of bleed; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - advantages: rapidly reversible by protamine
  - disadvantages: must monitor aPTT or heparin levels with adjustment of dose to reach therapeutic level (~2x normal value); monitor platelet counts for development of HIT
- alternatives to LMWH and UFH
  - direct thrombin inhibitors (hirudin, lepirudin, argatroban) and direct factor Xa inhibitors (apixaban, rivaroxaban)
  - thrombolytic drugs (e.g. streptokinase, tPA) reserved for acute limb/life-threatening thrombosis, and low bleeding risk

## Long-Term Treatment

- anticoagulation therapy
  - warfarin
    - standard treatment; should be initiated with heparin overlap: dual therapy for at least 48 hours with INR >2, due to initial prothrombotic state secondary to warfarin's inhibition of natural anticoagulants protein C/S, half-life of vitamin K factors and risk of warfarin-induced skin necrosis
    - INR: warfarin dosed to maintain INR at 2-3, monitor twice weekly for 1-2 wk
      - discontinue heparin after INR>2.0 for 2 consecutive days
  - direct oral anticoagulants (DOACs)
    - apixaban or rivaroxaban; with no laboratory monitoring required, patients with CrCl >25 ml/min (apixaban) or 30 ml/min (rivaroxaban)
    - dabigatran (factor IIa inhibitor): LMWH or IV heparin for at least 5-10 d before initiating dabigatran, patients with CrCl >30 mL/min
    - important drug interactions to consider for DOACs (no relevant food interactions however)
  - cancer patients: LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients; increasing evidence to support DOACs in cancer-associated thrombosis
- duration of anticoagulant treatment
  - provoked VTE with transient risk factor: 3 mo
  - provoked VTE with ongoing risk factor: consider indefinite therapy with annual reassessment
  - first unprovoked VTE: at least 3 mo, subsequent reassessment
  - unprovoked proximal DVT or PE: consider indefinite therapy with annual reassessment
  - second unprovoked VTE: consider indefinite therapy
  - cancer-associated DVT: at least 3 mo, longer if continued evidence of cancer
- IVC filters
  - temporary filter indicated only if acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding) or if require interruption of anticoagulation (i.e. for urgent surgery)
  - must be retrieved once safe to do so as filter is pro-thrombotic in the long-term (consider anticoagulation if not retrieved)
- special considerations
  - pregnancy: treat with LMWH during pregnancy, then LMWH or warfarin for 6 wk post-partum (minimum total anticoagulation time of 3-6 mo, but must include 6 wk post-partum, as this is a high risk period); avoid warfarin in pregnancy due to teratogenicity, avoid DOAC in pregnancy (due to lack of data) and if breastfeeding in postpartum period

**Duration of Treatment with Vitamin K Antagonists in Symptomatic Venous Thromboembolism**
Cochrane DB Syst Rev 2009;CD001367
**Study**: Meta-analysis of 8 RCTs (2994 patients) comparing different durations of treatment with vitamin K antagonists in patients with symptomatic VTE.
**Results**: In patients treated with vitamin K antagonists for a prolonged period, the reduction in risk of recurrent VTE remained consistent regardless of the period of time since the index event (OR 0.18; 95% CI 0.13-0.26). In addition, there was no observed excess of VTE recurrences following cessation of prolonged treatment (i.e. rebound phenomenon) (OR 1.24; 95% CI 0.91-1.69). However, patients who received prolonged treatment had a persistent increase in their risk of major bleeding complications (OR 2.61; 95% CI 1.48-4.61).
**Conclusion**: Prolonged treatment with vitamin K antagonists leads to a consistent reduction in the risk of recurrent VTE for as long as therapy is continued. Therapy should be discontinued when the risk of harm from major bleeding (which remains constant over time) is of greater concern than the absolute risk of recurrent VTE (which declines over time). No specific recommendation was made regarding optimal duration of treatment.

**Common Medications that Interact with Warfarin**
- Acetaminophen (interference with vitamin K metabolism)
- Allopurinol
- NSAIDs (GI injury)
- Fluconazole
- Metronidazole
- Sulfamethoxazole
- Tamoxifen

**Initiation of Warfarin Therapy Requires Bridging with Heparin Therapy for 4-5 Days**
- 10 mg loading dose (for example) of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state
- Warfarin decreases Factor VII levels in first 48 h, INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after ~4 d)

**Low Risk Surgical Patients**
<40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal, or thoracic surgery

**Moderate Risk Surgical Patients**
>40 yr, >1 risk factor for VTE, GA >30 min

**High Risk Surgical Patients**
>40 yr, surgery for malignancy or lower extremity orthopedic surgery lasting >30 min, inhibitor deficiency, or other risk factor

**High Risk Medical Patients**
Heart failure, severe respiratory disease, ischemic stroke and lower limb paralysis, confined to bed and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, IBD)

- surgery: avoid elective surgery in the first 3 mo after a venous thromboembolic event
  - pre-operatively: IV heparin may be used up to 4-6 h pre-operatively
  - perioperatively: warfarin or DOACs discontinued for at least 3-5 d pre-operatively (consider mechanism of drug clearance)
  - post-operatively: IV heparin, LMWH, DOAC can be used for anticoagulation (consult with surgeon prior to re-initiation)
  - for patients at high risk for thromboembolism (VTE <12 wk, recurrent VTE, antiphospholipid antibody syndrome, atrial fibrillation with prior stroke, and mechanical heart valve), IV heparin or LMWH (bridging) should be considered before and after the procedure while the INR is below 2.0

### Prophylaxis

- consider for those with a moderate to high risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), and intermittent pneumatic compression (IPC)
- UFH 5000 IU SC bid, UFH 5000 IU SC tid or LMWH as per hospital protocol (e.g. enoxaparin 40 mg SC daily, dalteparin 5000 U SC qid), and DOACs for orthopedic surgery thromboprophylaxis

**Table 30. Contraindications of Anticoagulant Therapy**

| Absolute Contraindications to Treatment | Relative Contraindications to Treatment |
|---|---|
| Active bleeding | Mild-moderate bleeding diathesis or thrombocytopenia |
| Severe bleeding diathesis or platelet count <20 x $10^9$/L (<20,000/$mm^3$) | Brain metastases |
| Intracranial bleeding | Recent major trauma |
| Neurosurgery or ocular surgery within 10 d | Recent stroke |
| | Major abdominal surgery within past 2 d |
| | GI/GU bleeding within 1-4 d |
| | Endocarditis |
| | Severe hypertension (sBP >200 or dBP >120) |

### Treatment of Pulmonary Embolism

- see Respirology, R19

# Hematologic Malignancies and Related Disoders

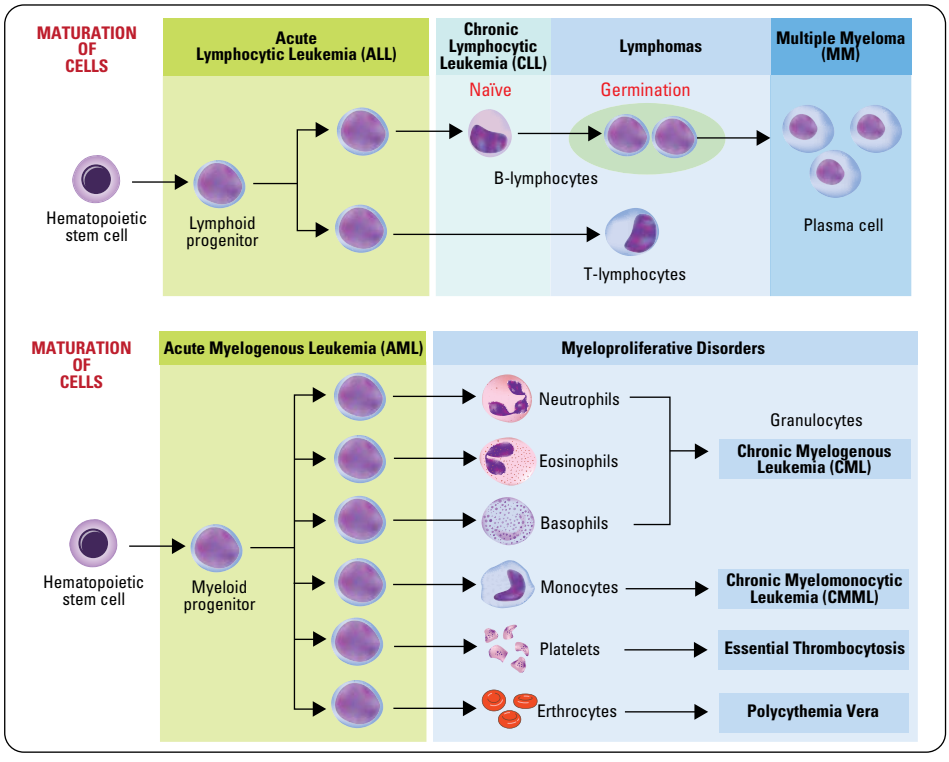


**Figure 15. Hematopoietic derivation of hematologic disorders**

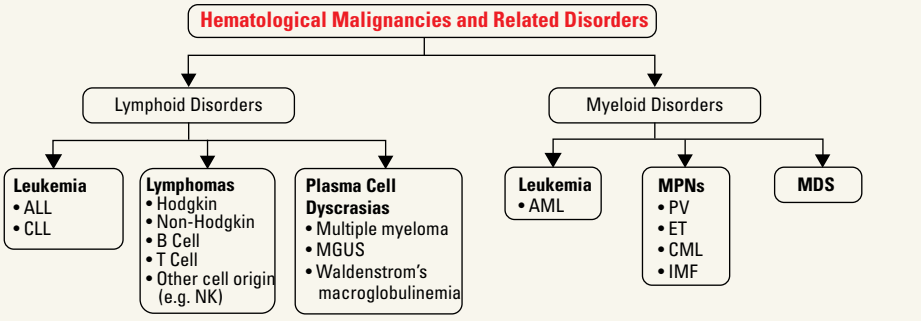

**Typical Age of Presentation of Leukemias**
- ALL: Children and older adults
- CML: 40-60 yr
- AML, CLL: >60 yr

**Leukemia:** malignant cells arise in bone marrow that may spread elsewhere (including blood, lymph nodes, and lymphoid tissue)
**Lymphoma:** malignant cells arise in lymph nodes and lymphoid tissues that may spread elsewhere (including blood and bone marrow)
**BUT** the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes)

**Acute Leukemia**
**Definition (WHO):** presence of 20% blast cells or greater in the peripheral blood or bone marrow at presentation
**Classification:** divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

Auer rods are pathognomonic for AML

**Basic initial workup for all hematological malignancies:**
1. ALL CHILDBEARING WOMEN must have a b-HCG pre initiation of treatment of any cancer diagnosis
2. ALL PATIENTS MUST HAVE HBsAb, HBsAg, HBcAb collected irrespective of cancer diagnosis and must be treated to avoid reactivation
3. All aggressive lymphoma patients must be screened for HIV
4. All patients must be screened for TB risk factors

ALL = acute lymphocytic leukemia; AML = acute myeloid leukemia; CLL = chronic lymphocytic leukemia; CML = chronic myeloid leukemia; ET = essential thrombocythemia; IMF = idiopathic myelofibrosis; MDS = myelodysplastic syndromes; MGUS = monoclonal gammopathy of unknown significance; MPN = myeloproliferative neoplasms; PV = polycythemia vera

**Figure 16. Overview of hematologic malignancies and related disorders**

# Myeloid Malignancies

## Acute Myeloid Leukemia

### Definition
- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

### Epidemiology
- incidence increases with age; median age of onset is 65 yr old; 80% of acute adult leukemias
- accounts for 10-15% of childhood leukemias

### Risk Factors
- male, older age, smoking, obesity, myelodysplastic syndromes (MDS), benzene, radiation, Down Syndrome, alkylating agents and radiation therapy as treatment for previous malignancy

### Pathophysiology
- etiology subdivided into:
  - primary: *de novo*
  - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood – risk of leukostasis
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; tumour lysis syndrome

### Clinical Features
- signs and symptoms develop over a period of weeks
- manifestations of bone marrow failure
  - anemia, thrombocytopenia (associated with DIC in promyelocytic leukemia), neutropenia (even with normal WBC), leads to infections, and fever
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - extramedullary involvement
  - hepatosplenomegaly (in ALL)
  - lymphadenopathy (not marked in ALL)
  - gonads (in ALL)
  - skin: leukemia cutis or myeloid sarcoma
  - eyes: hemorrhages and/or whitish plaques, Roth spots, cotton wool spots, and vision changes (uncommon)
- leukostasis/hyperleukocytosis syndrome (medical emergency)
  - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, and priapism
  - associated with AML more than ALL
- metabolic effects; aggravated by treatment
  - increased uric acid → nephropathy, gout
  - release of phosphate → decreased $Ca^{2+}$, decreased $Mg^{2+}$
  - release of procoagulants → DIC (higher risk in acute promyelocytic leukemia)
- tumour lysis syndrome
  - hyperkalemia pre-treatment from blastic proliferation $K^+$ after treatment (from lysed cells). Note – some forms of AML can present with hypokalemia due to secreted muraimdase that causes $K^+$ wasting from renal tubules

### Investigations
- blood work
  - CBC: anemia, thrombocytopenia, variable WBC (most often cytopenias + blasts)
  - INR, aPTT, fibrin degradation products (FDP), fibrinogen (in case of DIC)
  - increased LDH, increased uric acid, increased $PO_4^{3-}$ (released by leukemic blasts), decreased $Ca^{2+}$, in/decreased $K^+$
  - baseline renal and liver function tests
  - if considering treatment: screen for HepB, HepC, HIV, CMV
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- bone marrow aspirate for definitive diagnosis
  - blast count: AML >20% (normal is <5%)
  - morphologic, cytochemical, and/or immunophenotypic features are used to establish lineage and maturation
- CXR to rule out pneumonia; ECG, MUGA scan prior to chemotherapy (cardiotoxic)

### Treatment
- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
- all AML subtypes are treated similarly, except acute promyelocytic leukemia (APL) with t(15:17) translocation

**1. Induction**: chemotherapy to induce complete remission of AML
  - several possible regimens
  - patients with poor response to initial induction therapy – worse prognosis
  - must ensure reversal of DIC, platelet transfusions if <10

**2. Consolidation**: to prevent recurrence
  - intensive consolidation chemotherapy
  - stem cell transplantation – allogeneic (younger patients with better performance status)

- supportive care
  - fever: C&S of all orifices, CXR, and start antibiotics
  - platelet and RBC transfusions ± EPO
  - prevention and treatment of metabolic abnormalities
    - allopurinol, rasburicase for prevention of hyperuricemia
  - leukostasis
    - needs immediate cytoreductive therapy (i.e. hydroxyurea)
  - treatment strategy for APL
    - APL is an emergency as DIC is often presented at diagnosis
    - all-trans-retinoic acid (ATRA) added to induce differentiation; arsenic trioxide and ATRA combination therapy for APL is non-inferior to traditional chemotherapy

**Cure:** survival that parallels age-matched population
**Complete Remission:** tumour load below threshold of detectable disease (normal peripheral blood film, normal bone marrow with <5% blasts, normal clinical state)

### Prognosis
- achievement of first remission
  - 70-80% if ≤60 yr old, 50% if >60 yr old
  - median survival 12-24 mo
  - prognosis is most related to 1) cytogenetics; classified as favourable, intermediate, or adverse and 2) molecular studies (i.e. $NPM1^+$/FLT3- mutations)
  - prognosis depends on cytogenetics, age, performance status, prior cytotoxic agents, or radiation therapy

## Myelodysplastic Syndromes

### Definition
- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias, and a variable risk of transformation to acute leukemias
- syndromes defined according to World Health Organization (WHO) classifications

MDS is a cause of macrocytic anemia

### Pathophysiology
- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in bone marrow (usually hypercellular); formed elements sometimes exhibit morphological and functional defects
- intramedullary apoptosis: programmed cell death within bone marrow
- both processes lead to reduced mature cells in periphery
- <30% develop AML

### Risk Factors
- elderly, post-chemotherapy, exposures (benzene, tobacco, radiation), inherited genetic abnormalities
- incidence: 50 persons per million per year, rises to 200-400 per million per year for age 70 or older

### Clinical Features
- highly variable, commonly presents with symptoms of anemia (fatigue and dyspnea), thrombocytopenia (bruising, bleeding or petechiae), and neutropenia (recurrent infections) over months-years

### Investigations
- diagnosed by:
  - anemia ± thrombocytopenia ± neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bi-lobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size, and cytoplasm (e.g. giant hypogranular platelets)
- bone marrow aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - bone marrow: dysplastic and often normocellular/hypercellular
  - cytogenetics: high risk (partial or total loss of chromosome 7) and complex (>3 abnormalities)

### Treatment
- low risk of transformation to acute leukemia (IPSS-R Very Low or Low)
  - erythropoietin stimulating agents weekly is first line in reducing transfusion requirements (EPO level must be <500)
  - hypomethylating agents: decitabine and azacitidine
  - if 5q deletion based on cytogenetics: lenalidomide PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high risk of transformation to acute leukemia (IPSS-R intermediate, high or very high)
  - supportive care
  - consider stem cell transplantation according to patient factors (age, frailty, overall health)
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacytidine), histone deacetylase inhibitors

### Prognosis
- Revised International Prognostic Scoring System (IPSS-R) uses 5 factors to estimate mean survival:
  - cytology, % bone marrow blasts, hemoglobin, platelets, and absolute neutrophil count
  - based on the calculated score, a patient's MDS prognostic risk is "Very Low", "Low", "Intermediate", "High", or "Very High" with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

**Use of Epoetin and Darbepoetin in Patients with Cancer**
Blood 2008;111:25-41
Clinical practice guideline update by American Societies of Hematology and Clinical Oncology (2010).
**Initial Recommendations**
1. Initiate an erythropoiesis-stimulating agent (ESA) when hemoglobin (Hb) is 100 g/L (10 g/dL) in patients with palliative chemotherapy-associated anemia to decrease the need for transfusions.
2. Discontinue ESAs when patient not responding to treatment beyond 6-8 wk.
3. Monitor iron stores and supplement iron intake for ESA-treated patients when necessary.
4. Use ESAs cautiously with chemotherapy or in patients with an elevated risk for thromboembolic complications.
5. It is not recommended that ESA be used for therapy in patients with cancer who are not receiving chemotherapy, as it increases thromboembolic risks and lowers survival rate. Patients with low-risk myelodysplasia are an exception.

# Myeloproliferative Neoplasms

### Definition
- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (leading to abnormalities in erythrocytes, platelets, and other cells of myeloid lineage)

### Epidemiology
- mainly middle-aged and older patients (peak 60-80 yr)

### Prognosis
- may develop marrow fibrosis with time
- all disorders may progress to AML

**Myelodysplastic Syndromes**
ineffective maturation
**Myeloproliferative Neoplasms**
overproduction of mature cells

**Table 31. Chronic Myeloproliferative Disorders**

| | CML | PV | IMF | ET |
|---|---|---|---|---|
| **Hct** | ↓/N | ↑↑ | ↓ | N |
| **WBC** | ↑↑ | ↑ | ↑/↓ | N |
| **Plt** | ↑/↓ | ↑ | ↑/↓ | ↑↑↑ |
| **Marrow Fibrosis** | ± | ± | +++ | ± |
| **Splenomegaly** | +++ | + | +++ | + |
| **Hepatomegaly** | + | + | ++ | – |
| **Genetic Association** | *bcr-abl* mut. (95+%) | JAK2 mut. (96%) | JAK2 mut. (~50%)<br>CALR mut (~30%) | JAK2 mut. (~50%)<br>CALR mut (~30%) |

CML = chronic myeloid leukemia; ET = essential thrombocythemia; IMF = idiopathic myelofibrosis; PV = polycythemia vera CALR = Calreticulin

# Chronic Myeloid Leukemia

Basophilia is uncommon in other medical conditions

### Definition
- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

### Epidemiology
- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

### Pathophysiology
- Philadelphia chromosome (Ph)
  - translocation between chromosomes 9 and 22
  - the c-Abl proto-oncogene is translocated from chromosome 9 to "breakpoint cluster region" (BCR) of chromosome 22 to produce BCR-Abl fusion gene, an constitutively active tyrosine kinase

## Clinical Features

- 3 clinical phases
  - chronic phase: 85% diagnosed here
    - few blasts (<10%) in peripheral film
    - ± slightly elevated eosinophils and basophils
    - no significant symptoms
  - accelerated phase: impaired neutrophil differentiation
    - circulating blasts (10-19%) with increasing peripheral basophils (pruritus)
    - CBC: thrombocytopenia <100 x $10^9$/L
    - cytogenetic evidence of clonal evolution
    - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
  - blast crisis: more aggressive course, blasts fail to differentiate
    - blasts (>20%) in peripheral blood or bone marrow; reflective of acute leukemia (1/3 ALL, 2/3 AML)
- clinical feature
  - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
  - nonspecific symptoms
    - fatigue, weight loss, malaise, excessive sweating, fever
  - secondary to splenic involvement
    - early satiety, LUQ pain/fullness, shoulder tip pain (referred)
    - splenomegaly (most common physical finding)
  - anemia
  - bleeding: secondary to platelet dysfunction
  - pruritus, PUD: secondary to increased blood histamine
  - leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

**Chronic Myeloproliferative Neoplasias: Six Year Follow-Up of Patients Receiving Imatinib for the First-Line Treatment of CML**
Leukemia 2009;23:1054-1061
**Study**: The Randomized Study of Interferon vs. STI571 (IRIS) trial enrolled patients with chronic phase chronic myeloid leukemia (CML-CP) to either imatinib (n=533) or interferon-α (IFN -α) plus cytarabine (n=553).
**Results**: Assessing the imatinib arm specifically at the sixth year point, there were no reports of disease progression to accelerated phase (AP) or blast crisis (BC), toxicity profile was unchanged, and cytogenetic response rate was 82%. Estimated event-free survival was 83% and rate of freedom from progression to AP and BC was 93%.
**Conclusion**: This 6-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

## Investigations

- elevated WBC, decreased/normal RBC, increased/decreased platelets, increased basophils
  - WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
- peripheral blood film
  - leukoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
  - presence of different mid-stage progenitor cells differentiates it from AML
- bone marrow
  - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
- molecular and cytogenetic studies of bone marrow or peripheral blood for Philadelphia chromosome
- abdominal imaging for spleen size

Detection of the *bcr-abl* fusion gene is a diagnostic test for CML (present in over 90% of patients)

## Treatment

- **prophylactic:** allopurinol
- **chronic phase**
  - imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for bcr-abl. 2nd/ 3rd generation can be trialed based on patient co-morbidities as first line.
    - if loss of response or intolerance (~40%), trial of 2nd or 3rd generation tyrosine kinase inhibitors (TKIs): dasatinib, nilotinib, or bosutinib. Note: Ponatinib only provided for the T315I mutation.
  - interferon-α: may improve response to tyrosine kinase inhibitors; typically now only used for pregnant patients
  - hydroxyurea in palliative setting to reduce WBC
- **accelerated phase or blast phase**
  - for imatinib-naive patients, use imatinib
  - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard AML induction
- stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones
- treatment success is monitored based on therapeutic milestones
  - hematologic: improved WBC and platelet counts, reduced basophils
  - cytogenetic: undetectable Philadelphia-chromosome in the bone marrow
  - molecular: reduction/absence of bcr-abl transcripts in periphery and marrow

## Prognosis

- survival dependent on response
  - those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
  - those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis – usually within 3-5 yr)
  - 2/3 acute phase CML have cellular features similar to AML
    - unresponsive to remission induction
  - 1/3 acute phase CML have cellular features similar to ALL
    - remission induction (return to chronic phase) achievable

# Polycythemia Vera

## Definition
- stem cell disorder characterized by elevated RBC mass (erythrocytosis) ± increased white cell and platelet production
- diagnosis (WHO 2016) requires meeting either all 3 major criteria, or the first 2 major criteria and the minor criterion
  - Major Criteria
    1. hemoglobin >165 g/L in men, >160 g/L in women, OR Hct >49% in men or >48% in women, OR increased red cell mass (>25% above mean normal predicted value)
    2. bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
    3. presence of JAK2 V617F or JAK2 exon 12 mutation
  - Minor Criterion
    1. serum erythropoietin level below reference range for normal (must have at least two major criteria if using erythropoietin level)

## Clinical Features
- symptoms are secondary to high red cell mass and hyperviscosity (see *Erythrocytosis*, H6)
- thrombotic complications: DVT, PE, Budd-Chiari (hepatic vein thrombosis), portal vein thrombosis, thrombophlebitis, increased incidence of stroke, and MI
  - due to increased blood viscosity, increased platelet number and/or activity
  - bleeding complications: epistaxis, gingival bleeding, ecchymoses, and GI bleeding
  - if high platelet counts: associated with acquired vWD
- erythromelalgia (burning pain in hands and feet and erythema of the skin)
  - associated with platelets >400 x $10^9$/L
  - pathognomonic microvascular thrombotic complication in PV and ET
- pruritus, especially after warm bath or shower (40%) due to cutaneous mast cell degranulation and histamine release
- epigastric distress, PUD
  - due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow due to increased blood viscosity
- gout (hyperuricemia), due to increased cell turnover
- characteristic physical findings
  - plethora (ruddy complexion) of face (70%), palms
  - splenomegaly (70%), hepatomegaly (40%)

## Investigations (see *Erythrocytosis*, H6)
- must rule out secondary polycythemia if high Epo level

## Treatment
- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antihistamines: as needed

## Prognosis
- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

Erythromelalgia is a pathognomonic microvascular thrombotic complication in PV and ET

**Cardiovascular Events and Intensity of Treatment in Polycythemia Vera**
NEJM 2013;368:22-33
**Study**: Prospective, RCT, mean follow-up of 28.9 mo. Blinding not described.
**Population**: 365 patients with JAK2-positive polycythemia vera being treated with phlebotomy, hydroxyurea, or both.
**Intervention**: Patients were randomized to a target hematocrit <45% (low-hematocrit group) or 45-50% (high-hemtocrit group).
**Outcome**: Composite of time until death from cardiovascular causes of major thrombotic events.
**Results**: The hazard ratio (HR) for the primary outcome was 3.91 (95% CI 1.45-10.53, p=0.007), while the HR for the primary outcome plus superficial venous thrombosis was 2.69 (95% CI 1.19-6.12, p=0.02) for the high-hematocrit vs. low-hematocrit group.
**Conclusions**: The hematocrit target of <45% was associated with a lower incidence of CV death, major thrombotic events, and superficial venous thrombosis in patients with polycythemia vera.

**Efficacy and Safety of Low-dose Aspirin® in Polycythemia Vera**
NEJM 2004;350:114-124
**Study**: Double-blind, placebo-controlled, RCT.
**Participants**: 518 patients with polycythemia vera (PV) with no clear indication for, or contraindication to, ASA therapy.
**Intervention**: Patients received either low-dose ASA 100 mg daily (n=253) or placebo (n=265) and were followed for up to 5 yr.
**Primary Outcome**: Cumulative rate of (I) nonfatal MI, nonfatal stroke, or death from cardiovascular causes and the cumulative rate of (II) the previous 3 plus PE and major venous thrombosis.
**Results**: Primary outcomes (I) and (II) were reduced with treatment compared to placebo (RR 0.41; p=0.09 and RR 0.4; p=0.03, respectively). There were no differences in overall or cardiovascular mortality and major bleeding episodes.
**Conclusion**: Low-dose ASA can safely prevent thrombotic complications in patients with PV.

# Idiopathic Myelofibrosis

## Definition
- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

## Epidemiology
- rare, median age at presentation is 65 yr

## Pathophysiology
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

## Clinical Features
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
- hepatomegaly (70%) → may get portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A "leukoerythroblastic" blood film (RBC and granulocyte precursors) implies bone marrow infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)

IMF typically has a dry BM aspirate and teardrop RBCs (aspiration gives no blood cells)

### Investigations
- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH (2º to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased $B_{12}$ (2º to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- molecular test: JAK2 (70%) and calreticulin (25%) mutations
- bone marrow aspirate: "dry tap" in as many as 50% of patients (no blood cells aspirated)
- bone marrow biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

### Treatment
- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors (Ruxolitinib)
- symptomatic treatment
  - transfusion for anemia
  - erythropoietin: 30-50% of patients respond
  - androgens for anemia (e.g. danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, and systemic symptoms
    - interferon-α (as second line therapy)
    - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis, and symptomatic splenomegaly

### Prognosis
- Dynamic International Prognostic Scoring System (DIPSS) Plus for IMF uses 5 risk factors along with karyotype, platelet count, and transfusion status to predict survival
  - presence of constitutional symptoms; age >65; hemoglobin <100 g/L; leukocyte count >25,000/$mm^3$; circulating blast cells ≥1%
  - based on the calculated score, a patient's IMF is categorized as "low", "intermediate 1", "intermediate 2", or "high" with a mean survival of 185, 78, 35, and 16 mo, respectively
- risk of transformation to AML (8-10%)

**A Double-Blind, Placebo-Controlled Trial of Ruxolitinib for Myelofibrosis**
NEJM 2012;366:799-807
**Study**: Double-blinded RCT of 309 patients with myelofibrosis randomized to ruxolitinib or placebo.
**Outcome**: Primary outcome was reduction in spleen volume of >35% at 24 wk. Secondary outcomes were durability of response, symptom burden, and overall survival.
**Results**: A greater proportion of patients on ruxolitinib had reduction in spleen volume >35% (41.9% vs. 0.7%) and this was sustained in 67% at 48 wk. Ruxolitinib also led to greater symptom improvement (45% vs. 5.3%) and less mortality (13 vs. 24). There was no difference in rate of discontinuation due to adverse events (11.0% vs. 10.6%) but anemia and thrombocytopenia were more common with ruxolitinib.
**Conclusions**: Ruxolitinib reduced spleen size, improved symptoms and improved survival, compared with placebo.

## Essential Thrombocythemia

### Definition
- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia

### Epidemiology
- increases with age; F:M = 2:1, but F=M at older age

### Diagnosis (2008 WHO Criteria Revised in 2016) requires meeting all four criteria
1. sustained platelet count >450 x $10^9$/L
2. bone marrow biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. not meeting WHO criteria for PV, primary myelofibrosis, bcr-abl CML, or myelodysplastic syndrome or other myeloid neoplasms
4. demonstration of JAK2 V617F, calreticulin or MPL mutation (or in its absence another clonal marker), no evidence for reactive thrombocytosis

### Clinical Features
- often asymptomatic
- vasomotor symptoms (40%)
  - headache (common), dizziness, syncope
  - erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation → microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding (often GI; associated with platelets >1000 x $10^9$/L)
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

### Investigations
- CBC: increased platelets; may have abnormal platelet aggregation studies or vWD studies
- JAK2 PCR assay; if negative, CALR PCR assay
- bone marrow hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- increased $K^+$, increased $PO_4^{3-}$ (2º to release of platelet cytoplasmic contents)
- diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

### Treatment
- low dose ASA if previous history of thrombotic event, ≥1 cardiovascular risk factors, older, or symptomatic
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st-line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)

**Etiology of Secondary Thrombocythemia**
- Infection
- Inflammation (IBD, arthritis)
- Malignancy
- Hemorrhage
- Iron deficiency
- Hemolytic anemia
- Post splenectomy
- Post chemotherapy

**Anagrelide vs. Hydroxyurea for Essential Thrombocythemia: ANAHYDRET Study, A Randomized Controlled Trial**
Blood 2013;121:1720-8
**Study**: Prospective, non-inferiority, RCT. Majority of patients followed beyond 1 yr.
**Population**: 259 previously untreated, high-risk patients with essential thrombosis as per the WHO guidelines.
**Intervention**: Patients were randomized to receive either non-immediate release formulation of anagrelide or hydroxyurea.
**Outcome**: Examined platelet counts, hemoglobin levels, leukocyte counts, and occurrence of ET-related events.
**Results**: The hazard ratio (HR) of developing thrombocythemia was 1.19 (95% CI 0.61-2.30). The HR for a reduction of hemoglobin was 1.03 (95% CI 0.57-1.81), and 0.92 (95% CI 0.57-1.46) for leukocytosis. There was no statistical difference in occurrence of major or minor arterial or venous thrombosis, severe or minor bleeding events, or rate of discontinuation between the two arms.
**Conclusions**: In patients with ET, anagrelide is non-inferior to hydroxyurea in the prevention of thrombotic complications.

There is an asymptomatic "benign" form of essential thrombocythemia with a stable or slowly rising platelet count; treatment includes observation, ASA, sulfinpyrazone, or dipyridamole

# Lymphoid Malignancies

## Acute Lymphoblastic Leukemia

### Definition

- malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells of the marrow
- WHO subdivides ALL into two types depending on cell of origin
  - 1. B-cell: precursor B lymphoblastic leukemia
  - 2. T-cell: precursor T lymphoblastic leukemia
- the French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as morphology is not prognostic

75% of ALL occurs in children <6 yr old; second peak at age 40

### Clinical Features

- see *Acute Myeloid Leukemia*, H38 for full list of symptoms
- distinguish ALL from AML based on Table 32
- clinical symptoms usually secondary to:
  - bone marrow failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), and thrombocytopenia
  - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

### Investigations

- CBC: increased leukocytes >10 x $10^9$/L (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- may have increased uric acid, $K^+$, $PO_4^{3-}$, $Ca^{2+}$, LDH
- PT, aPTT, fibrinogen, D-dimers for DIC
- leukemic lymphoblasts lack specific morphological (no granules) or cytochemical features, therefore diagnosis depends on immunophenotyping
- cytogenetics: Philadelphia (Ph) chromosome in ~25% of adult ALL cases
- CXR: patients with ALL may have a mediastinal mass
- LP prior to systemic chemotherapy to assess for CNS involvement (ensure adequate platelet count and PT/PTT)
- HIV, HepB, HepC serologies

### Treatment

- eliminate abnormal clonal cells
  1. induction chemotherapy: to induce complete remission (undetectable leukemic blasts, restore normal hematopoiesis)
  2. consolidation and/or intensification of chemotherapy
     - consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
     - intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (2-3 yr) to prevent relapse
  4. prophylaxis: CNS radiation therapy or methotrexate (intrathecal or systemic)
- hematopoietic stem cell transplantation: potentially curative (due to pre-implant myeloablative chemoradiation and post-implant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high

**Treatment of ALL vs. AML**
- No proven benefit of maintenance chemotherapy in AML
- No routine CNS prophylaxis in AML

### Prognosis

- depends on response to initial induction or if remission is achieved following relapse
- good prognostic factors: young, WBC <30 x $10^9$/L, T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
- achievement of first remission: 60-90%
- childhood ALL: 75% long-term remission (>5 yr)
  - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of BCR-Abl fusion gene (associated with chemotherapeutic resistance)
- adult ALL: 30-40% 5 yr survival

**Table 32. Differentiating AML From ALL**

| AML | ALL |
|---|---|
| Big people (adults) | Small people (kids) |
| Big blasts | Small blasts |
| Big mortality rate | Small mortality rate (kids) |
| Lots of cytoplasm | Less cytoplasm |
| Lots of nucleoli (3-5) | Few nucleoli (1-3) |
| Lots of granules and Auer rods | No granules |
| Myeloperoxidase, Sudan black stain | PAS (periodic acid-Schiff) |
| Maturation defect beyond myeloblast or promyelocyte | Maturation defect beyond lymphoblast |

**To Differentiate AML from ALL:**
Remember **Big** and Sm**ALL**

# Lymphomas

## Definition

- collection of lymphoid malignancies in which malignant lymphocytes accumulate at lymph nodes and lymphoid tissues
  - leading to lymphadenopathy, extranodal disease, and constitutional symptoms

**American Society of Hematology Choosing Wisely Recommendation**
Limit surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma

**Table 33. Ann Arbor System for Staging Lymphomas**

| Stage | Description |
|---|---|
| I | Involvement of a single lymph node region OR extralymphatic organ/site (Stage IE) |
| II | Involvement of two or more lymph node regions or an extralymphatic site and one or more lymph node regions on same side of diaphragm |
| III | Involvement of lymph node regions on both sides of the diaphragm; may or may not be accompanied by single extra lymphatic site or splenic involvement |
| IV | Diffuse involvement of one or more extralymphatic organs including bone marrow |

- Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma
- Prognostic scores are different for indolent versus aggressive lymphomas
- Highly aggressive lymphomas act like acute leukemias

- subtypes
  - A = absence of B-symptoms (see *Approach to Lymphadenopathy*, H12)
  - B = presence of B-symptoms

**Table 34. Chromosome Translocations**

| Translocation | Gene Activation | Associated Neoplasm |
|---|---|---|
| t(2;5) | ALK1 mutation | Anaplastic large cell lymphoma |
| t(8;14) | c-Myc activation | Burkitt's lymphoma |
| t(14;18) | Bcl-2 activation | Follicular lymphoma |
| t(11;14) | Overexpression of cyclin D1 protein | Mantle cell lymphoma |
| t(11;18) | MALT1 activation | Mucosa-associated lymphoid tissue (MALT) |

# Hodgkin Lymphoma

## Definition

- malignant proliferation of lymphoid cells with Reed-Sternberg cells (thought to arise from germinal centre B-cells)

Hodgkin is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells

## Epidemiology

- bimodal distribution with peaks at 20 yr and >50 yr
- association with Epstein-Barr virus in up to 50% of cases and causal role not determined

## Clinical Features

- asymptomatic lymphadenopathy (70%)
  - non-tender, rubbery consistency
  - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
- splenomegaly (50%) ± hepatomegaly
- mediastinal mass
  - found on routine CXR, may be symptomatic (cough)
  - rarely may present with superior vena cava syndrome and pleural effusion
- systemic symptoms
  - B symptoms (especially in widespread disease; fever in 30%, night sweats, weight loss) and pruritus
- non-specific/paraneoplastic
  - alcohol-induced pain in nodes and nephrotic syndrome
- starts at a single site in lymphatic system (node) and spreads first to adjacent nodes
  - disease progresses in contiguity with lymphatic system

Hodgkin lymphoma classically presents as a painless, non-tender, firm, rubbery enlargement of superficial lymph nodes, most often in the cervical region

## Investigations

- CBC
  - anemia (chronic disease, rarely hemolytic), eosinophilia, lymphopenia, platelets normal or increased early disease, and decreased in advanced disease
- biochemistry
  - HIV, HepB, HepC serologies
  - liver enzymes and/or LFTs (liver involvement)
  - renal function tests (prior to initiating chemotherapy)
  - ALP, $Ca^{2+}$ (bone involvement)
  - ESR, LDH (monitor disease progression)
- imaging
  - CXR, CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), and PET scans

  - cardiac function assessment (MUGA scan or echocardiography): for patients at high risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA, and malnourished), treatment can be cardiotoxic
  - PFTs: if history of lung disease (COPD, smoking, and previous radiation to lung)
- excisional lymph node or core biopsy confirms diagnosis
- bone marrow biopsy to assess marrow infiltration (only necessary if B-symptoms, PET positive marrow on imaging, or cytopenia)

### Treatment

- stage I-II: chemotherapy (ABVD) followed by involved field or involved site radiotherapy (XRT)
- stage III-IV: chemotherapy (ABVD) with XRT for bulky disease
- relapse, resistant to therapy: high dose chemotherapy and autologous stem cell transplant
  - PET scan results essential in clarifying disease response

Treatment of HL depends on stage; treatment of NHL depends on histologic subtype

### Complications of Treatment

- cardiac disease: secondary to XRT, adriamycin is also cardiotoxic
- pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
- infertility: recommend sperm banking
- secondary malignancy in irradiated field
  - <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
  - solid tumours of lung, breast; >8 yr after treatment
  - non-Hodgkin lymphoma
- hypothyroidism: post XRT

### Prognosis

- Hasenclever adverse prognostic factors:
  1. serum albumin <40 g/L
  2. hemoglobin <105 g/L
  3. male
  4. stage IV disease
  5. age ≥45 yr
  6. leukocytosis (WBC >1.5 x $10^9$/L)
  7. lymphocytopenia (lymphocytes <0.06 x $10^9$/L or <8% of WBC count or both)
- prognostic score
  - each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

**International Prognostic Factors Project 1998**

| Prognostic Factors | FFP |
|---|---|
| 0 | 84% |
| 1 | 77% |
| 2 | 67% |
| 3 | 60% |
| 4 | 51% |
| 5-7 | 42% |

FFP = freedom from progression at 5 yr

## Non-Hodgkin Lymphoma

### Definition

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

### Classification

- multiple classification systems exist at present and may be used at different centres
- can originate from both B- (85%) and T- or NK- (15%) cells
  - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt's lymphoma, and mantle cell lymphoma
    - WHO/REAL classification system: 3 categories of NHLs based on natural history
    - indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, and mantle cell lymphoma
    - aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
    - highly aggressive (~5% of NHL): e.g. Burkitt's lymphoma
  - T-cell NHL: e.g. mycosis fungoides (skin), TCL-NOS, and anaplastic large cell lymphoma

### Clinical Features

- painless superficial lymphadenopathy, usually >1 lymph node region
- usually presents as widespread disease (exception is aggressive lymphoma)
- constitutional symptoms not as common as in Hodgkin lymphoma
- cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when bone marrow is involved
- abdominal signs ± hepatosplenomegaly, retroperitoneal and mesenteric involvement (second most common site of involvement)
- oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
- extranodal involvement: most commonly GI tract; also testes, bone, and kidney
- CNS involvement in 1% (often with HIV)

**NHL: Associated Conditions**

- Immunodeficiency (e.g. HIV)
- Autoimmune diseases (e.g. SLE)
- Infections (e.g. EBV)

### Investigations

- CBC
  - normocytic normochromic anemia
  - autoimmune hemolytic anemia rare
  - advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic anemia
- peripheral blood film may show lymphoma cells
- flow cytometry of peripheral blood lymphocytosis is valuable for low-grade NHL

- biochemistries, HIV, HepB, HepC serologies
  - increase in uric acid
  - abnormal LFTs in liver metastases
  - increased LDH (rapidly progressing disease and poor prognostic factor)
- staging: CT neck, chest, abdomen, pelvis and bone marrow biopsy
- PET imaging must be done post therapy to ensure post treatment remission
- diagnosed by:
  - lymph node biopsy: excisional biopsy preferred, FNA unreliable
  - bone marrow biopsy: not optimal for diagnosis as BM involved in only 30% of high grade lymphomas

## Treatment

- localized disease (e.g. GI, brain, bone, head and neck)
  - radiotherapy to primary site and adjacent nodal areas
  - adjuvant chemotherapy
  - surgery: splenic marginal zone lymphoma
- indolent lymphoma: goal of treatment is symptom management
  - watchful waiting
  - radiation therapy for localized disease
  - bendamustine plus rituximab, an anti-CD20 antibody, is superior to CHOP and rituximab (CHOP-R) for advanced stage disease (StIL trial)
  - obinutuzumab superior to rituximab for advanced stage follicular lymphoma (GALLIUM Trial)
- aggressive lymphoma: goal of treatment is curative
  - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
  - radiation for localized/bulky disease
  - CNS prophylaxis with high-dose methotrexate if certain sites involved (testicular)
  - relapse, resistant to therapy: high dose chemotherapy, autologous SCT
- highly aggressive lymphoma
  - Burkitt lymphoma: short bursts of intensive chemotherapy "CODOX-M" chemotherapy regimen also often used ± IVAC with Rituximab
  - CNS prophylaxis and tumour lysis syndrome prophylaxis

**Common Chemotherapeutic Regimens**
**CHOP:** cyclophosphamide, hydroxydoxorubicin (Adriamycin®), vincristine (Oncovin®), prednisone
**VAD:** vincristine, adriamycin, dexamethasone
**ABVD:** adriamycin, bleomycin, vinblastine, dacarbazine
**BEACOPP:** bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone

## Complications

- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- bowel perforation
- tumour lysis syndrome (particularly in very aggressive lymphoma) see *Tumour Lysis Syndrome*, H52

## Prognosis

- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used (5 adverse prognostic factors): age >60; >4 nodal areas; elevated LDH; Lugano stage III-IV; hemoglobin <120 g/L
  - based on calculated risk, mean 5 yr survival ranges from 53-91%
  - rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrand 2-4); elevated LDH; >1 extranodal site
  - based on calculated risk, mean 5 yr survival ranges from 26-73%
  - ~40% rate of cure

**Table 35. Characteristics of Select Non-Hodgkin Lymphomas**

| | Follicular Lymphoma | Diffuse Large B-Cell Lymphoma (DLBCL) | Burkitt Lymphoma | Mantle Cell Lymphoma |
|---|---|---|---|---|
| **Percentage of NHLs** | 22-30% | 33% | <1% adult NHLs<br>30% childhood NHLs | 6% |
| **Genetic Mutation** | Bcl-2 activation | Bcl-2, Bcl-6, Myc rearrangements | c-Myc activation | Overexpression of cyclin D1 (Bcl-1 activation) |
| **Classification** | Indolent | Aggressive (high-grade) | Very aggressive | Indolent |
| **Risk Factors** | Middle-age – elderly | Previous CLL (Richter's transformation: 5% CLL patients progress to DLBCL) | 1. Endemic: African origin, EBV-associated<br>2. Sporadic: no EBV<br>3. HIV-related: AIDS-defining illness | Male (M:F = 4:1) |
| **Clinical Features** | Widespread painless LAD* ± bone marrow involvement<br>Frequent transformation to aggressive lymphoma<br>Very responsive to chemoradiation treatment | Rapidly progressive LAD and extranodal infiltration<br>50% present at stage I/II, 50% widely disseminated | Endemic form: massive jaw LAD "Starry-sky" histology<br>High risk of tumour lysis syndrome upon treatment | Often presents Stage IV with palpable LAD<br>Involvement of GI tract (lymphomatosis polyposis), Waldeyer's Ring<br>5 yr survival 25% |

*LAD = lymphadenopathy

# Malignant Clonal Proliferations of Mature B-Cells

**Table 36. Characteristics of B-Cell Malignant Proliferation**

| | CLL | Lymphoplasmacytic Lymphoma | Myeloma |
|---|---|---|---|
| **Cell Type** | Lymphocyte | Plasmacytoid | Plasma cell |
| **Protein** | IgM if present | IgM | IgG, A, light chain (rarely M, D, or E) |
| **Lymph Nodes** | Very common | Common | Rare |
| **Hepatosplenomegaly** | Common | Common | Rare |
| **Bone Lesions** | Rare | Rare | Common |
| **Hypercalcemia** | Rare | Rare | Common |
| **Renal Failure** | Rare | Rare | Common |
| **Immunoglobulin Complications** | Common | Rare | Rare |

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality)

## Chronic Lymphocytic Leukemia

### Definition
- indolent disease characterized by clonal malignancy of mature B-cells

### Epidemiology
- most common leukemia in Western world
- mainly older patients; median age 70 yr
- M>F

### Pathophysiology
- accumulation of neoplastic lymphocytes in blood, bone marrow, lymph nodes, and spleen

### Clinical Features
- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38°C, or night sweats for ≥2 wk without evidence of infection, extreme fatigue)
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (DAT positive), ITP, hypogammaglobulinemia ± neutropenia
- bone marrow failure: late, secondary to marrow involvement by CLL cells

### Investigations
- CBC: clonal population of B lymphocytes >5 x $10^9$/L
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells

characteristic flow cytometry of peripheral blood
  - CD5, CD20dim, CD23
- cytogenetics: FISH (dictates response to therapy and prognosis). imaging must be done post therapy to ensure post treatment remission v=
- bone marrow aspirate
  - lymphocytes >30% of all nucleated cells
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis), or mixed (25%)

Smudge cells are artifacts of damaged lymphocytes from slide preparation

### Natural History and Treatment
- natural history: indolent and incurable; most cases show slow progression
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- first line therapy is dictated by cytogenetic status and patient co-morbidities
  - observation if early, stable, asymptomatic
    - treatment options vary by region; commonly fludarabine + cyclophosphamide + rituximab (FCR) in fit patients with normal CrCl; bendamustine + rituximab (BR) in less fit
    - chlorambucil + anti-CD20 obinutuzumab in the elderly
    - Ibrutinib (BTK inhibitor) in patients with IgVH mutation negativity and/ p53 positivity
  - corticosteroids, IVIg: especially for autoimmune phenomena
  - radiotherapy for isolated bulky nodes
- molecular therapies
  - Idelalisib – PI3K inhibitor
  - Ibrutinib – BTK (Bruton's tyrosine kinase) inhibitor
  - Venetoclax – BCL-2 inhibitor

### Prognosis
- 9 yr median survival, but varies greatly
- prognosis predicted by Rai staging based on leukocytosis and cytogenetic status
- low risk: lymphocytosis in blood and bone marrow only
- intermediate risk: lymphocytosis with enlarged nodes in any site or splenomegaly, hepatomegaly
- high risk: lymphocytosis with disease-related anemia (<110 g/L) or thrombocytopenia (<100 x $10^9$/L)

### Complications
- bone marrow failure
- immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, and impaired T-cell function)
- polyclonal or monoclonal gammopathy (often IgM)
- hyperuricemia with treatment
- 5% undergo Richter's transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 35)

## Multiple Myeloma

### Definition
- neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
- usually single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory
- preceded by asymptomatic myeloma or MGUS

### Epidemiology
- incidence 3 per 100,000, most common plasma cell malignancy
- increased frequency with age; median age of diagnosis is 68 yr; M>F

### Pathophysiology
- malignant plasma cells secrete monoclonal antibody
  - 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
    - IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
    - 15-20% produce free light chains or light chains alone found in either:
      - serum as an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
      - urine has Bence-Jones protein
  - <5% are non-secretors

### Clinical Features and Complications
- bone disease: pain (usually back), bony tenderness, pathologic fractures
  - lytic lesions are classical (skull, spine, proximal long bones, ribs)
  - increased bone resorption secondary to osteoclast activating factors such as PTHrP
- anemia: weakness, fatigue, pallor
  - secondary to bone marrow suppression
- weight loss
- infections
  - usually *S. pneumoniae* and Gram-negatives
  - secondary to suppression of normal plasma cell function
- hypercalcemia: N/V, confusion, constipation, polyuria, and polydipsia
  - secondary to increased bone turnover
- renal disease/renal failure
  - most frequently causes cast nephropathy (see Nephrology, NP33)
- bleeding
  - secondary to thrombocytopenia, may see petechiae, purpura
  - can also be caused by acquired von Willebrand disease
- extramedullary plasmacytoma
  - soft tissue mass composed of monoclonal plasma cells, purplish colour
- hyperviscosity: may manifest as headaches, stroke, angina, and MI
  - rare in MM as secondary to increased viscosity caused by IgM protein (more common in WM/ LPL)
- amyloidosis
  - accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  - may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
- neurologic disease: muscle weakness, pain, and paresthesias
  - radiculopathy caused by vertebral fracture and extramedullary plasmacytoma
  - spinal cord compression (10-20% of patients) is a medical emergency

**Multiple Myeloma**
**SLiM CRAB**
**S**ixty percent plasma cells in bone marrow specimen
**L**ight chain ratio >100
**M**RI lytic lesion >0.5 cm
**C**alcium >2.80 mmol/L
**R**enal failure (Cr >176 mmol/L)
**A**nemia
**B**ony lesions (lytic lesions or osteoporosis felt to be caused by myeloma)

**Amyloid**
The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues

Found in a variety of clinical disorders and can cause systemic (e.g. MM [light chains]) or localized amyloidosis (e.g. Alzheimer disease [AB amyloid])

## Investigations

- CBC
  - normocytic anemia, thrombocytopenia, and leukopenia
  - rouleaux formation on peripheral film
- biochemistry
  - increased $Ca^{2+}$, increased ESR, decreased anion gap, increased Cr, albumin, β2-microglobulin (as part of staging), and proteinuria (24 h urine collection)
- monoclonal proteins
  - serum protein electrophoresis (SPEP): demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  - urine protein electrophoresis (UPEP): demonstrates light chains in urine = Bence-Jones protein (15% secrete only light chains)
  - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- bone marrow aspirate and biopsy
  - often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for fluorescence *in situ* hybridization (FISH) or cytogenetics (prognostic implications)
- skeletal series (X-rays), MRI if symptoms of cord compression
  - presence of lytic lesions and areas at risk of pathologic fracture
  - bone scans are not useful since they detect osteoblast activity
- β2-microglobulin, LDH, and CRP are poor prognosticators
  - HepBsAb, HepBsAg, HepBcAb

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis

**Light Chain Disease**
15% of MM produce only light chains
Renal failure is a major problem
Kappa > lambda light chain has better prognosis

## Diagnosis

- International Myeloma Working Group Criteria ("SLiM CRAB"):
  - Sixty (60) percent or greater abnormal plasma cells on bone marrow examination
  - Light chain ratio (free, involved/uninvolved) of 100 or more in the blood (involved must be at least 100 mg/L)
  - MRI with more than one bone lesion (5 mm or greater)
  - CRAB – presence of end-organ damage related to plasma cell dyscrasia, such as:
    - increased serum $Ca^{2+}$
    - renal failure
    - anemia
    - lytic bone lesions

## Treatment

- non-curative
- treatment goals
  - improvement in quality of life (improve anemia, reverse renal failure, prevent fractures)
  - prevention of progression and complications
  - increase overall survival
- autologous stem cell transplant if <65 yr old
  - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents (i.e. immunomodulatory drugs - IMIDs or proteasome inhibitors - PI)
- chemotherapy if >65 yr old or transplant-ineligible
  - pending on patient co-morbidities can include a combination of: melphalan, prednisone, cyclophosphamide, PI (i.e. bortezomib), IMIDs, anti-CD38 agents (e.g. daratumumab)
- dexamethasone and bortezomib if ARF; bortezomib ± dexamethasone in light chain amyloidosis
- supportive management
  - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  - local XRT for bone pain, spinal cord compression
  - kyphoplasty for vertebral fractures to improve pain relief and regain height
  - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, erythropoietin for anemia, and DVT prophylaxis
- all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient's comorbidities, and preferences

**Serum Free Light Chain Ratio is an Independent Risk Factor for Progression in MGUS**
Blood 2005;106:812-817
**Purpose**: To determine whether the presence of monoclonal free kappa or lambda immunoglobulin light chains in MGUS increases the risk of progression to malignancy.
**Methods**: Retrospective study with median follow-up of 15 yr. Baseline serum samples obtained from 1383 MGUS patients seen at the Mayo clinic between 1960-1994. 1148 baseline samples were obtained within 30 d of diagnosis.
**Results**: Malignant progression had occurred in 87 (7.6%) patients. In 379 (33%) patients, an abnormal serum free light chain (FLC) ratio was detected. There was a significantly higher risk of progression in patients with an abnormal FLC ratio relative to patients with a normal ratio (hazard ratio, 3.5; 95% CI 2.3-5.5; p<0.001). This finding was independent of the size and type of the serum monoclonal (M) protein. In high-risk MGUS patients (abnormal serum FLC ratio, non-IgG MGUS, high serum M protein level [≥1.5 gm/dL]), the risk of progression at 20 yr was 58% compared to 37% in high-intermediate-risk MGUS (two risk factors), 21% low-intermediate risk (with one risk factor) and 5% low-risk (no risk factors).
**Conclusions**: The presence of an abnormal FLC ratio is a clinically and statistically significant predictor of progression in MGUS. The low-risk subset of patients with MGUS accounts for 40% of all MGUS patients and have a small lifetime risk of progression, thus less follow-up can be justified.

## Prognosis

- ISS - International Staging System (β2-microglobulin and albumin) used to stage and estimate prognosis
- revised ISS for risk stratification: combination of original ISS, cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy), and LDH
- median survival based on stage, usually 3-7 yr

# Monoclonal Gammopathy of Unknown Significance

### Definition
- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr of age
  - asymptomatic

### Diagnosis
- presence of a serum monoclonal protein (M protein) at a concentration <30 g/L
- <10% plasma cells in bone marrow
- absence of SLiM CRAB
- 0.3-1% of patients develop a hematologic malignancy each yr
  - patients with M protein peak ≥15 g/L or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with annual history, physical, CBC, Cr, calcium, albumin, and serum protein electrophoresis (considered pre-malignant)
- all patients must have skeletal imaging at diagnosis (typically skeletal survey ± MRI spine as per symptoms)

# Waldenstrom's Macroglobulinemia (WM)

### Definition
- WM aka Lymphoplasmacytic Lymphoma (LPL)
- proliferation of lymphoplasmacytoid cells
  - presence of monoclonal IgM paraprotein

Waldenstrom's macroglobulinemia accounts for 85% of all cases of hyperviscosity syndrome

### Clinical Features
- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, and cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, and retinal lesions
- key complication to avoid: hyperviscosity syndrome
  - because IgM (unlike IgG) confined largely to intravascular space

### Investigations and Diagnosis
- bone marrow shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely shows hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, and high ESR if hyperviscosity not present
- HepB, HepC serologies (NOTE: can be associated with HepC; HepC eradication can put LPL into remission)

### Treatment
- Bendamustine – R/R-CVP chemotherapy, alkylating agents (chlorambucil), nucleoside analogues (fludarabine), rituximab, or combination therapy
- if HepC positive – treat HepC prior to a trial of chemotherapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

# Complications of Hematologic Malignancies

## Hyperviscosity Syndrome

### Definition
- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum Igs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of cases

### Clinical Features
- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, and stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

### Treatment
- plasmapheresis, chemotherapy

# Tumour Lysis Syndrome

### Definition
- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, leukemia)

### Clinical Features
- metabolic abnormalities
  - cells lyse, releasing $K^+$, uric acid, $PO_4^{3-}$ (increased levels)
  - $PO_4^{3-}$ binds $Ca^{2+}$ (decreased $Ca^{2+}$)
- complications
  - lethal cardiac arrhythmia (increased $K^+$)
  - acute kidney injury (formerly known as renal failure) see Nephrology, NP19

### Treatment
- prevention
  - aggressive IV hydration
  - alkalinization not recommended due to risk of calcium phosphate or xanthine precipitation in renal tubules
  - allopurinol or rasburicase
  - correction of pre-existing metabolic abnormalities
- dialysis

# Blood Products and Transfusions

### Blood Products
- RBCs, platelets and coagulation factors (frozen plasma [FP], cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and platelet-rich plasma
  - platelet-rich plasma is further fractionated into platelets and plasma
    - need to pool together multiple units to obtain therapeutic amounts
    - FP (previously known as FFP) is plasma frozen within 24 h of collection
    - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures

**Blood Groups**

| Group | Antigen (on RBC) | Antibody (in serum) |
|---|---|---|
| O | H | Anti-A, anti-B |
| A | A | Anti-B |
| B | B | Anti-A |
| AB | A and B | Nil |

### Specialized Products
- irradiated blood products
  - prevent proliferation of donor T-cells in potential or actual bone marrow transplant recipients
  - used for immunocompromised patients or for patients on purine analogue chemotherapy, first-degree relatives, HLA-matched products and intrauterine transfusions, Hodgkin lymphoma
- CMV-negative blood products
  - potential transplant recipients
  - neonates
  - AIDS patients
  - seronegative pregnant women

In Canada, blood products are leukodepleted via filtration immediately after donation; therefore it is considered:
- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV negative (because CMV is found in leukocytes)

# Red Blood Cells

### Packed Red Blood Cells
- stored at 4°C
- transfuse within 42 d of collection, otherwise cell lysis may result in hyperkalemia
- infuse each unit over 2 h (max of 4 h)

1 unit of pRBC will increase Hb by approximately 10 g/L or increase Hct by 4%

### Indications for Packed RBC Transfusion
- Hb <70 g/L; this may change as per patient's tolerance or symptoms
  - maintain Hb between 70 and 100 g/L during active bleeds
- consider maintaining a higher Hb for patients with:
  - CAD/unstable coronary syndromes
  - uncontrolled, unpredictable bleeding
  - impaired pulmonary function
  - increased $O_2$ consumption

**American Society of Hematology Choosing Wisely Recommendation**
Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe hemoglobin range (70-80 g/L) in stable non-cardiac patients

### Selection of Red Cells for Transfusion

- when anticipating an RBC transfusion, the following should be ordered:
  - group and screen: determines the blood group and Rh status of the recipient as well as the presence of autoantibodies vs. major/minor blood group antigens in the patient's serum
  - cross-match: involves mixing the recipient's blood with potential donor blood and looking for agglutination (takes 30-45 min)
- when blood is required, several options are available
  - 1st-line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
  - 2nd-line: donor blood of the same group and Rh status as the recipient
  - 3rd-line: O- blood for females of reproductive age; O+ blood for all others

# Platelets

**Table 37. Platelet Products**

| Product | Indication |
|---|---|
| **Random Donor (Pooled)** | Thrombocytopenia with bleeding |
| **Single Donor Platelets** | Potential BMT recipients. Refractory to pooled platelets. |
| **HLA Matched Platelets** | Refractory to pooled or single donor platelets, presence of HLA antibodies |

- stored at 20-24°C
- random donor platelets are transfused from a pool of 4 units; this should increase the platelet count by ≥15 x $10^9$/L
- single donor platelets (transfused as single units) should increase the platelet count by 40-60 x $10^9$/L
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies, consumption (bleeding, sepsis), or hypersplenism may be present

**Table 38. Indications for Platelet Transfusion**

| Plt (x $10^9$/L) | Indications |
|---|---|
| **<10** | Non-immune thrombocytopenia |
| **<20** | Procedures not associated with significant blood loss |
| **<50** | Procedures associated with blood loss or major surgery (>500 mL EBL) |
| **<100** | Pre-neurosurgery or head trauma |
| **Any** | Platelet dysfunction (or antiplatelet agents) and marked bleeding |

### Relative Contraindications of Platelet Transfusion

- TTP, HIT, post-transfusion purpura, and HELLP

# Coagulation Factors

**Table 39. Coagulation Factor Products**

| Product | Indication |
|---|---|
| Frozen plasma (FP) | Depletion of multiple coagulation factors (e.g. sepsis, DIC, dilution, TTP/HUS, liver disease), emergency reversal of life-threatening bleeding secondary to warfarin overdose |
| Cryoprecipitate (enriched fibrinogen, vWF, VIII, XIII) | Hemophilia A (Factor VIII deficiency) – use in emergencies<br>von Willebrand disease – use in emergencies<br>Hypofibrinogenemia |
| Humate P or Wilate | von Willebrand disease<br>Hemophilia A |
| Factor VIII concentrate | Factor VIII deficiency (Hemophilia A) |
| Factor IX concentrate | Factor IX deficiency (Hemophilia B) |
| Recombinant factor VIIa | Factor VII deficiency with bleeding/surgery, Hemophilia A or B with inhibitors, Glanzmann thrombasthenia |
| Prothrombin complex concentrate; PCC (Octaplex®, Beriplex®) | Reversal of warfarin therapy or vitamin K deficiency in bleeding patient or in patient requiring urgent (<6 h) surgical procedure, urgent non-specific "reversal" of direct Xa inhibitors |
| Activated prothrombin complex concentrate; aPCC (FEIBA) | Hemophilia A or B with inhibitors, urgent non-specific "reversal" of direct thrombin inhibitors |

**Transfusion Requirements in Critical Care (TRICC)**
NEJM 1999;340:409-417
**Study**: Multicentre, RCT.
**Participants**: 838 critically ill patients with euvolemia after initial treatment and hemoglobin less than 9 g/dL within 72 h of ICU admission.
**Intervention**: Patients receiving a transfusion followed either (1) a restrictive strategy (RS; n=418) in which red cells were transfused if hemoglobin was less than 7.0 g/dL and then maintained at 7 to 9 g/dL) or (2) a liberal strategy (LS; n=420) in which transfusions occurred when the hemoglobin was less than 10.0 g/dL and then maintained at 10 to 12 g/dL.
**Primary Outcome**: Mortality at 30 d and severity of organ dysfunction.
**Results**: Mortality rates at 30 d were similar between groups. However, mortality rates were significantly lower with the RS among less acutely ill patients (8.7% and RS group and 16.1% in LS group; p=0.03) and among those <55 yr of age (5.7% RS and 13% LS; p=0.02), but did not differ in a subgroup with clinically significant cardiac disease.
**Conclusion**: A RS of red cell transfusion is at least as effective as, and possibly superior to, a LS transfusion in critically ill patients.

**Liberal or Restrictive Transfusion in High-Risk Patients After Hip Surgery (FOCUS)**
NEJM 2011;365:2453-2462
**Study**: Multicentre RCT.
**Participants**: 2016 patients aged greater than 50 yr with a history of or risk factors for cardiovascular disease and hemoglobin (Hb) level below 10 g/dL after hip-fracture surgery.
**Intervention**: Patients were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL).
**Primary Outcome**: Mortality or inability to walk across a room without human assistance on a 60 d follow-up.
**Results**: Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups.
**Conclusion**: A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 d follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.

**Group & Screen vs Cross-Matching:**
G&S: ABO Group + Rh factor
Cross-Matching: match recipient's serum with donor's packed RBC or antibodies

# Acute Blood Transfusion Reactions

## IMMUNE

### Acute Hemolytic Transfusion Reactions
- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1 in 40,000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - maintain BP with vigorous IV fluids ± inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

### Febrile Nonhemolytic Transfusion Reactions
- due to alloantibodies to WBC, platelets or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 0-6 h of transfusion
- risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- presents with fever ± rigors, facial flushing, headache, myalgia, hypotension
- treatment
  - rule out hemolytic reaction or infection
  - if temperature <38°C, continue with transfusion but decrease rate and give antipyretics
  - if temperature >38°C, stop transfusion, give antipyretics and anti-histamine

### Allergic Nonhemolytic Transfusion Reactions
- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1 in 100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenydramine, steroids, epinephrine, IV fluids, and bronchodilators

### Transfusion-Related Acute Lung Injury
- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - insidious, acute onset of pulmonary insufficiency
  - profound hypoxemia ($PaO_2/FiO_2$ <300 mmHg)
  - bilateral pulmonary edema on CXR
  - pulmonary artery wedge pressure <18 mmHg
  - no clinical evidence of left atrial hypertension
- pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post transfusion and resolves in 24-72 h
- risk per unit of blood is 1 in 10,000
  - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
- inform blood bank; patient and donor testing will be arranged

## NONIMMUNE

### Transfusion-Associated Circulatory Overload
- due to impaired cardiac function and/or excessive rapid transfusion
- presentation: dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung, and increased venous pressure
- incidence: 1 in 700 and is becoming more common
- treatment: transfuse at lower rate, give diuretics and oxygen

### Bacterial Infection
- Gram-positive: *S. aureus, S. epidermidis, Bacillus cereus*
- Gram-negative: *Klebsiella, Serratia, Pseudomonas, Yersinia*
- overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

**DDx of Post-Transfusion Fever**
- Acute hemolytic transfusion reaction
- Febrile non-hemolytic transfusion reaction
- Bacterial contamination
- Allergy

**DDx of Post-Transfusion Dyspnea**
- Transfusion-associated circulatory overload (TACO)
- Transfusion-related acute lung injury (TRALI)
- Allergy (bronchospasm/anaphylaxis)

### Hyperkalemia
- due to $K^+$ release from stored RBC
- risk increases with storage time and if blood is irradiated and risk decreases if given fresh blood
- occurs in 5% of massively transfused patients
- treatment: see Nephrology, NP13

### Citrate Toxicity
- occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to $Ca^{2+}$ and causes signs and symptoms of hypocalcemia
- treatment: IV calcium gluconate (10 mL for every 2 units of blood)

### Dilutional Coagulopathy
- occurs with massive transfusion (>10 units)
- pRBC contains no clotting factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, cryoprecipitate, and platelets

## Delayed Blood Transfusion Reactions

### IMMUNE

### Delayed Hemolytic
- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
- occurs 5-7 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion
- N.B. serologic transfusion reactions are the development of alloantibodies in the absence of frank hemolysis

### Transfusion-Associated Graft Versus Host Disease
- transfused T-lymphocytes recognize and react against "host" (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

**Allogeneic SCT GVHD**
To reduce risk of GVHD development after allogeneic SCT, administer Inhibitors of T-cell activation, including cyclosporin A or tacrolimus

### NONIMMUNE

### Iron Overload
- due to repeated transfusions over long period of time (e.g. β-thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

### Viral Infection Risk
- HBV 1 in 1.1 to 1.7 million
- HCV 1 in 5 to 7 million
- HIV 1 in 8 to 12 million
- Human T-lymphotropic virus (HTLV) 1 in 1 to 1.3 million
- other infections include EBV, CMV, WNV (West Nile virus)

# Common Medications

## Antiplatelet Therapy

• see Figure 12a, *Platelet activation cascade*, H26

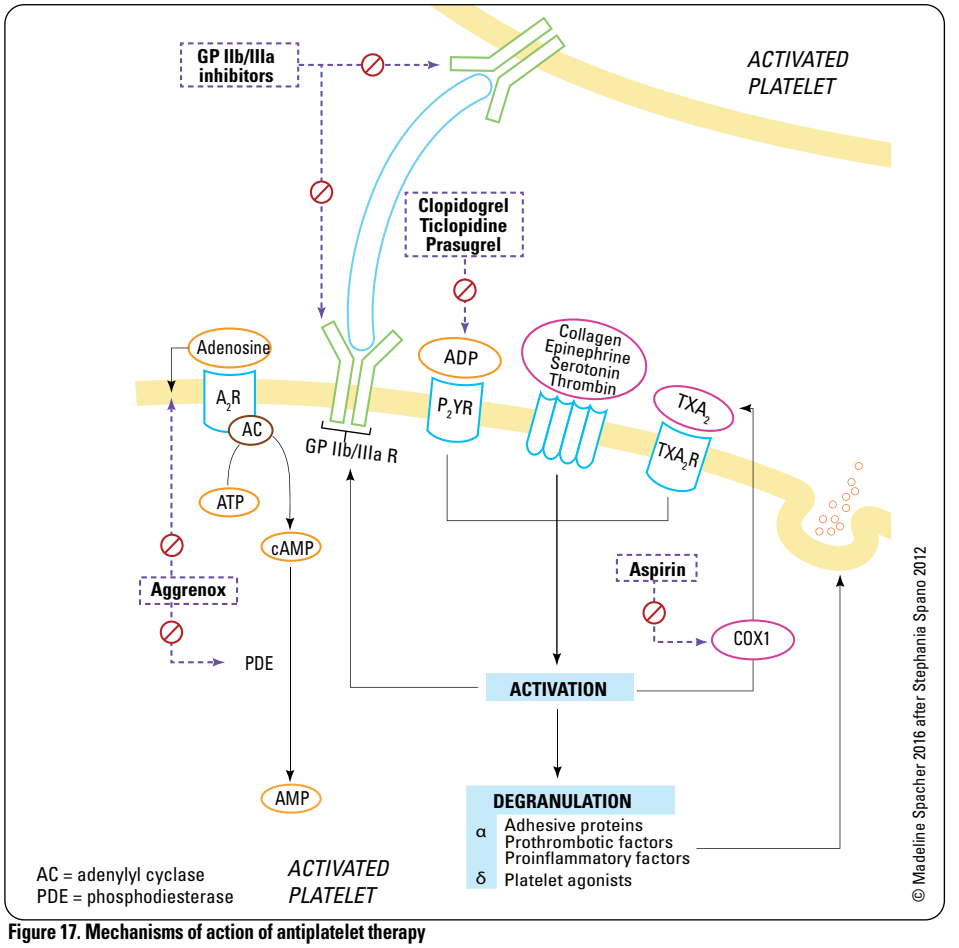

**Figure 17. Mechanisms of action of antiplatelet therapy**

**Table 40. Antiplatelet Therapy**

| | Mechanism of Action | Typical Dose/Route of Administration | Onset/Peak/ Duration | Specific Side Effects | Remarks |
|---|---|---|---|---|---|
| **Aspirin® (ASA)** | Irreversibly acetylates COX, inhibiting TXA2 synthesis, thus inhibiting platelet aggregation | Single loading 200-300 mg PO, followed by dose of 75-100 mg PO daily | Onset: 5-30 min<br>Peak: 0.25-3 h<br>Duration: 3-6 h (platelet inhibition lasts 7-10 d) | GI ulcer/bleeding<br>Tinnitus<br>Bronchospam<br>Angioedema<br>Reye's syndrome in pediatric patients | Indicated for stroke/MI prophylaxis<br>Reduce incidence of recurrent MI<br>Decrease mortality in post-MI patients<br>Contraindicated in patients with GI ulcers |
| **Aggrenox® (ASA + Dipyridamole)** | Dipyridamole increases intracellular cAMP levels, which inhibits TXA2 synthesis, leading to decreased platelet aggregation | 1 capsule PO bid | Peak: 75 min | H/A<br>Dyspepsia<br>N/V<br>Abdominal pain<br>Cardiac failure<br>Hemorrhoids | More effective than ASA in secondary prevention of stroke<br>Dipyridamole potentiates antiplatelet action of ASA |
| **Clopidogrel (Plavix®)** | Irreversibility inhibit ADP binding to platelets, thus decreased platelet aggregation | Loading dose 300 mg PO, then 75 mg daily | Onset: 2 h (loading dose)<br>Peak: 6 h (loading dose)<br>Duration: 5 d | URI<br>Chest pain<br>H/A<br>Flu-like syndrome<br>Depression<br>UTI<br>GI hemorrhage<br>Pancytopenia<br>May cause TTP | Prevention of cardiovascular events in high-risk patients<br>Clopidogrel is a prodrug requiring two-step activation to active metabolite<br>CYP2C19 poor metabolizers have diminished response to clopidrogrel<br>Caution with hepatic/renal impairment |
| **Prasugrel (Effient®)** | Same as clopidogrel | Loading dose 60 mg, then 5-10 mg PO daily | Onset: 30 min (loading dose)<br>Peak: 4 h (loading dose)<br>Duration: 5-10 d | Dizziness<br>H/A<br>Nervousness<br>Blurry vision | Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients<br>Higher potency compared to clopidogrel<br>No significant drug-drug interaction, although more data is required |

**Table 40. Antiplatelet Therapy** (continued)

| | Mechanism of Action | Typical Dose/Route of Administration | Onset/Peak/ Duration | Specific Side Effects | Remarks |
|---|---|---|---|---|---|
| **Ticagrelor (Brilinta®)** | Reversibly inhibit ADP binding to platelets | Loading dose 180 mg, then 90 mg PO bid | Onset: 30 min (loading dose) Peak: 1.5 h for prodrug, 2.5 h for active metabolite | Difficulty or laboured breathing Shortness of breath Tightness in chest Dizziness | Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel Ticagrelor is a prodrug that requires CYP3A4-mediated activation to active metabolite Drug-drug interactions with CYP3A4 inhibitors and inducers |
| **Glycoprotein IIb/IIIa Inhibitors (Reopro® [abciximab], Integrelin® [epti])** | Blocking GP II/IIIa receptor inhibits fibrinogen and vWF binding, leading to decreased platelet aggregation | Variable IV | Variable | Hypotension Back pain N/V Chest pain Abdominal pain Thrombocytopenia | Used most commonly in cardiac catheterization Contraindicated in PUD Monitoring aPTT/activated clotting time |

# Anticoagulant Therapy

**Table 41. Anticoagulant Therapy**

| | Mechanism of Action | Dose/Route of Administration | Onset/Peak/Duration | Reversing Agent | Monitoring | Specific Side Effects | Remarks |
|---|---|---|---|---|---|---|---|
| **Heparin** | Inhibition of FXa and FIIa, mediated via antithrombin | Variable, depends on indication; can be used IV or SC | Onset: Immediate (IV); 20-30 min (SC) | Protamine sulfate | aPTT (intrinsic pathway), UFH (anti-Xa) levels | Hemorrhage HIT Increased liver enzymes | Pregnancy: safe (does not cross placenta) |
| **Warfarin** | Vitamin K antagonist: inhibits production of II, VII, IX, X, proteins C and S | Individualized dosing by monitoring PT/INR; PO | Onset: 24-72 h Peak: 5-7 d Duration: 2-5 d | Vitamin K PCC FP | INR: maintain 2-3 (2.5-3.5 for certain mechanical valves) | Hemorrhage Cholesterol embolism syndrome Intraocular hemorrhage | Pregnancy: not used, can cross placenta (teratogenic) |
| **LMWH (enoxaparin, dalteparin, tinzaparin)** | Mainly FXa inhibition, some FIIa inhibition, both mediated via antithrombin | Variable, weight-based dose, depends on indication; SC/IV | Onset: 1-2 h Peak: 3-5 h Duration: 12-24 h | Partial reversibility with protamine sulfate | Anti-Xa levels in pediatrics, pregnancy and weight >150 kg | Hemorrhage Fever Increased liver enzymes <1% HIT | Increased bioavailability than heparin Can accumulate in patients low CrCl (<30 mL/min) Standard treatment of VTE in patients with malignancy |
| **Fondaparinux** | Selective FXa inhibition, mediated via antithrombin | Variable SC daily | Onset: 2 h Peak: 2-3 h | Not reversible | None | Anemia Fever Nausea Rash | Long half-life (17-21 h) Contraindicated in renal failure |
| **Rivaroxaban** | Direct FXa inhibitor | Variable, depends on indication; PO | Peak: 2-4 h | Andexanet alpha | Anti-Xa levels validated for Rivaroxaban may be used to detect presence of drug only | Syncope GI hemorrhage Menorrhagia | Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl>30 mL/min; must be taken with food; contraindicated in mechanical heart valves |
| **Apixaban** | Direct FXa inhibitor | PO bid | Onset: 3-4h Peak: 3-4 h | Andexanet alpha | Anti-Xa levels validated for Apixaban may be used to detect presence of drug only | Hemorrhage Nausea Anemia | Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >25 ml/min; contraindicated in mechanical heart valves |
| **Argatroban** | Direct thrombin inhibitor | Variable IV | Onset: 5-10 min Duration: 20-40 min | Not reversible | aPTT | Dyspnea Hypotension Fever | Indicated for treatment of heparin-induced thrombocytopenia, PCI; contraindicated in mechanical heart valves |
| **Dabigatran** | Direct thrombin inhibitor | 150 mg PO bid | Peak: 1 h | Not reversible | Dilute thrombin time may be used to detect presence of drug only; TT also sensitive for drug presence | GI upset Dyspepsia | Indicated for treatment of acute VTE (after 5-10 d parenteral therapy), secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl>30 mL/min; should be stored in blister pack; contraindicated in mechanical heart valves |

### Adverse Reactions of Heparin

- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- heparin-induced thrombocytopenia a hematologic emergency associated with venous or arterial thrombosis (see Table 22, H29)
- osteoporosis: with long-term use

### Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)

- increased bioavailability compared to unfractionated heparin
- increased duration of action
- SC route of administration
- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl <30 mL/min) can accumulate LMWH, therefore must adjust dose
- only partially reversible with protamine sulfate
- HIT is less common

**Table 42. Recommended Therapeutic INR Ranges for Common Indications for Vitamin K Antagonists (Warfarin)**

| Indication | INR Range |
|---|---|
| Prophylaxis of venous thrombosis (high-risk surgery) | 2.0-3.0 |
| Treatment of venous thrombosis | |
| Most cases of thrombosis with antiphospholipid antibody syndrome | |
| Treatment of pulmonary embolism | |
| Prevention of systemic embolism | |
| Tissue heart valves | |
| AMI (to prevent systemic embolism) | |
| Valvular heart disease | |
| Atrial fibrillation | |
| Bileaflet mechanical valve in aortic position | |
| Mechanical prosthetic mitral valves (high risk) | 2.5-3.5 |

AMI = acute myocardial infarction

**Table 43. Recommended Management of a Supratherapeutic INR**

| INR | Bleeding Present | Recommended Action |
|---|---|---|
| **>Therapeutic to 4.5** | No | Lower warfarin dose OR Omit a dose and resume warfarin at a lower dose when INR is in therapeutic range OR No dose reduction needed if INR is minimally prolonged |
| **>4.5 to 10.0** | No | Omit the next 1 to 2 doses of warfarin, monitor INR more frequently and resume treatment at a lower dose when INR is in therapeutic range OR Omit a dose and administer 1 to 2.5 mg oral vitamin K in patients with increased risk of bleeding |
| **>10.0** | No | Hold warfarin and administer 5 to 10 mg oral vitamin K; monitor INR more frequently and administer more vitamin K as needed; resume warfarin at a lower dose when INR is in therapeutic range |
| **Any** | Serious or life threatening | Hold warfarin and administer 10 mg vitamin K by slow IV infusion; supplement with four-factor prothrombin complex concentrate; monitor and repeat as needed |

# Chemotherapeutic and Biologic Agents Used in Oncology

**Table 44. Selected Chemotherapeutic and Biologic Agents**

| Class | Example | Mechanism of Action or Target |
|---|---|---|
| **Alkylating Agent** | • chlorambucil, cyclophosphamide, melphalan (nitrogen mustards)<br>• carboplatin, cisplatin<br>• dacarbazine, procarbazine<br>• busulfan<br>• bendamustine | Damage DNA via alkylation of base pairs<br>Leads to cross-linking of bases, abnormal base-pairing, DNA breakage |
| **Antimetabolites** | • methotrexate (folic acid antagonist)<br>• 6-mercaptopurine, fludarabine (purine antagonist)<br>• 5-fluorouracil (5-FU) (pyrimidine antagonist)<br>• hydroxyurea<br>• cytarabine | Inhibit DNA synthesis |
| **Antibiotics** | • adriamycin (anthracycline)<br>• bleomycin<br>• mitomycin C<br>• daunorubicin | Interfere with DNA and RNA synthesis |
| **Taxanes** | • paclitaxel<br>• docetaxel | Stabilize microtubules against breakdown once cell division complete |
| **Vinca-alkaloids** | • vinblastine<br>• vincristine<br>• vinorelbine | Inhibit microtubule assembly (mitotic spindles), blocking cell division |
| **Topoisomerase Inhibitors** | • irinotecan, topotecan (topo I)<br>• etoposide (topo II) | Interfere with DNA unwinding necessary for normal replication and transcription |
| **Steroids** | • prednisone<br>• dexamethasone | Immunosuppression |
| **Purine Analogues** | • fludarabine<br>• cladribine | Interferes with DNA synthesis |
| **Monoclonal Antibodies** | • trastuzumab (Herceptin®)<br>• bevacizumab (Avastin®)<br>• rituximab (Rituxan®), ofatumumab (Arzerra®), obinutuzumab (Gayzva®)<br>• cetuximab (Erbitux®)<br>• Daratumumab | HER2 antagonist<br>VEGF antagonist<br>CD20 antagonist<br>EGFR antagonist<br><br>CD38 antagonist |
| **Small Molecule Inhibitors** | • imatinib mesylate (Gleevec®)<br>• dasatinib<br>• nilotinib<br>• Bosutinib<br>• erlotinib (Tarceva®)<br>• gefitinib (Iressa®)<br>• bortezomib (Velcade®)<br>• sunitinib (Sutent®)<br>• ibrutinib (Imbruvica®)<br>• idealasib (Zyedlig®)<br>• ruxolitinib (Jakavi®)<br>• ponatinib (Iclusig®)<br>• Venetoclax<br>• Lenalidomide, Pomalidomide | *Bcr-Abl* inhibitor<br>*Bcr-Abl* inhibitor<br>*Bcr-Abl* inhibitor<br>*Bcr-Abl* inhibitorEGFR antagonist<br>EGFR antagonist<br>EGFR antagonist<br>26S proteasome inhibitor<br>VEGFR, PDGFR antagonist<br>BTK inhibitor<br>P13K inhibitor<br>JAK2 inhibitor<br>*Bcr-Abl* inhibitor<br>Immunomodulator |
| **CAR T cell therapy** | • tisagenlecleucel (Kymriah®)<br>• axicabtagene ciloleucel (Yescarta®) | Target CD19 |

# Landmark Hematology Trials

| Trial | Reference | Results |
|---|---|---|
| **Hematologic Malignancies and Related Disorders** | | |
| Hodgkin Lymphoma: ABVD vs. MOPP | *NEJM* 1992;327:1478-84 | In Hodgkin lymphoma, ABVD regimen has equal failure-free and overall survival to MOPP + ABVD, but less myelotoxicity; ABVD is standard chemotherapy for Hodgkin lymphoma |
| CHOP | *NEJM* 1993;328:1002-6 | In NHL, CHOP has lowest incidence of fatal toxic reactions and shows no significant difference from 3 other regimens in response or disease-free/overall survival; CHOP is the standard for advanced NHL |
| R-CHOP | *NEJM* 2002;346:235-42 | Addition of rituximab to CHOP increases complete response rate and prolongs event-free survival and overall survival in elderly with DLBCL |
| CML: Imatinib vs. IFN + Cytarabine | *NEJM* 2003;348:994-1004 | In patients with chronic-phase CML, imatinib was more effective than IFNα + cytarabine in inducing cytogenetic response and freedom from progression to accelerated phase/blast crisis |
| AZA-001 | *Lancet Oncol* 2009;10:223-32 | Azacitidine increases overall survival in higher-risk myelodysplastic syndrome than conventional care |
| CLL8 | *Lancet* 2010;376:1164-74 | Rituximab plus fludarabine and cyclophosphamide (FCR) improves progression-free and overall survival compared with fludarabine and cyclophosphamide alone (FC) in the treatment of CLL |
| VISTA | *JCO* 2010;28:2259-66 | Bortezomib plus melphalan and prednisone (MPV) is superior to melphalan and prednisone (MP) in overall survival of non-transplant-eligible multiple myeloma patients |
| MInT Group | *Lancet* 2011;12:1013-22 | Rituximab added to CHOP-like chemotherapy improved long-term outcomes for young patients with good-prognosis DLBCL |
| StIL | *Lancet* 2013;381(9873):1203-10 | Bendamustine plus rituximab is superior to R-CHOP in terms of progression-free survival and fewer toxic effects in patients with previously untreated indolent lymphoma |
| Ibrutinib vs. Ofatumumab in previously treated CLL | *NEJM* 2014;371:213-23 | Ibrutinib, as compared with ofatumumab, significantly improved progression-free survival, overall survival, and response rate among patients with previously treated CLL or SLL |
| ENDEAVOR | *Lancet Oncol* 2017;18(10):27 | Carfilzomib, as compared with bortezomib, significantly improved progression-free and overall survival in patients with relapsed or refractory multiple myeloma |
| Obinutuzumab for the First-Line Treatment of Follicular Lymphoma (GALLIUM) | *NEJM* 2017;377(14):1331 | Obinutuzumab (anti-CD20 monoclonal antibody), as compared with rituximab, improved progression-free survival for patients with advanced-stage follicular lymphoma |
| Phase I trial of Chimeric Antigen Receptor T cell (CAR-T) therapy for relapsed or refractory B-cell ALL | *NEJM* 2018;378(5):449-59 | CAR-T therapy achieved complete remission in 83% of patients in remission or refractory to previous treatment. Median survival was 12.9 mo. Typical median survival is 6 mo |
| **Thrombosis** | | |
| CLOT | *NEJM* 2003;349:146-53 | In patients with cancer and acute venous thromboembolism, LWMH was more effective than warfarin in reducing the risk of recurrent thromboembolism without increasing the risk of bleeding |
| PT1 | *NEJM* 2005;353:85-86 | Hydroxyurea plus low-dose ASA is superior to anagrelide plus low-dose ASA for patients with essential thrombocythemia at high risk for vascular events |
| ESPIRIT | *Lancet* 2006;367:1665-73 | ASA plus dipyridamole is recommended over ASA alone as antithrombotic therapy after cerebral ischemia of arterial origin |
| Dabigatran vs. Warfarin in VTE | *NEJM* 2009;361:2342-52 | In the treatment of venous thromboembolism, dabigatran is as effective as warfarin and also has a similar safety profile; note: many problems in the trial, making it less pivotal in having drug approval |
| EINSTEIN-PE | *NEJM* 2012;366:1287-97 | Among patients with acute PE, rivaroxaban is noninferior to warfarin in preventing recurrent VTE, and is associated with similar bleeding rates |
| AMPLIFY | *NEJM* 2013;369:799-808 | In patients with VTE who have completed 6-12 mo of anticoagulation, long-term apixaban treatment reduces recurrent VTE or all-cause mortality without increasing rates of major bleeding |
| RE-VERSE AD | *NEJM* 2015;373:511-20 | Idarucizumab for dabigatran reversal |
| **Blood Products and Transfusion** | | |
| Platelet Transfusion Threshold | *NEJM* 1997;337:1870-75 | The risk of major bleeding in patients with AML undergoing induction chemotherapy was similar whether the platelet-transfusion threshold was set at 20 or 10; use of the lower threshold reduced platelet usage by 21.5% |
| TRICC BP | *NEJM* 1999;340:409-17 | A restrictive strategy of red-cell transfusion (when Hb <70) is at least as effective as and possibly superior to a liberal transfusion strategy (when Hb <100) in ICU patients; one possible exception is patients with an acute MI or unstable angina |
| Dose of Platelet Transfusion | *NEJM* 2010;362:600-13 | Low dose prophylactic platelet transfusion decreases total number of platelets transfused but increases number of transfusions but not incidence of bleeding in patients with hypoproliferative thrombocytopenia |
| Transfusion in High-Risk Patients after Hip Surgery | *NEJM* 2011;365:2453-62 | A liberal transfusion strategy (Hb <100), as compared with a restrictive strategy (anemia symptoms or at physician discretion for Hb<80), did not reduce rates of death or inability to walk independently on 60 d follow-up or reduce in-hospital morbidity in elderly patients at high cardiovascular risk |
| Therapeutic Platelet Transfusion | *Lancet* 2012;380:1309-16 | Therapeutic platelet transfusions (when bleeding occurs) may be used if severe bleeding can be identified early in autologous stem-cell transplant patients; prophylactic transfusion (when platelets <10) should remain standard of care in AML patients |
| Transfusion Strategies for Acute Upper GI Bleeding | *NEJM* 2013;368:11-21 | As compared with a liberal transfusion strategy (Hb <90), a restrictive strategy (Hb<70) significantly improved outcomes in patients with acute upper gastrointestinal bleeding |
| **Other** | | |
| MSH | *NEJM* 1995;332:1317-22 | Hydroxyurea is effective in reduction of complications and clinical manifestations of sickle cell disease |
| ITP: Dexamethasone | *NEJM* 2003;349:831-36 | A 4 d course of high-dose dexamethasone is effective initial therapy for adults with immune thrombocytopenic purpura |
| CRASH-2 | *Health Technol Assess* 2013; 17(10):1-79 | Early administration of TXA safely reduced the risk of death in bleeding trauma patients and is highly cost-effective. Treatment beyond 3 hours of injury is unlikely to be effective |

| VZV | varicella-zoster virus |

# Principles of Microbiology

## Bacteriology

### Bacteria Basics

- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - Gram-positive (GP): thick, rigid layer of peptidoglycan
  - Gram-negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipoproteins and lipopolysaccharides
  - clinical significance: GN thick outer membrane makes it resistant to penicillin's mechanism of action
- acid-fast bacilli (AFB): high mycolic acid content in cell wall, "acid fast" as washout phase with acid-alcohol is ineffective in acid-fast bacteria (e.g. *Mycobacteria*, *Nocardia)*
- "atypical" bacteria: not seen on Gram stain and difficult to culture
  - obligate intracellular bacteria: e.g. *Chlamydia*, *Chlamydophilia*
  - bacteria lacking a cell wall: e.g. *Mycoplasma*
  - spirochetes: e.g. *Treponema pallidum*
- $O_2$ can be either vital or detrimental to growth
  - obligate aerobes: require $O_2$
  - obligate anaerobes: require environment without $O_2$
  - facultative anaerobes: can survive in environments with or without $O_2$

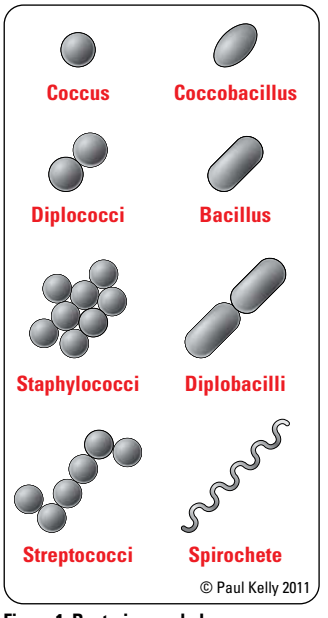

**Figure 1. Bacteria morphology**

### Mechanisms of Bacterial Disease

1. Adherence to and colonization of skin or mucous membranes
   - fimbriae (pili): microfilaments extending through the cell wall attach to epithelial cells (e.g. *E. coli* in the urinary tract)
2. Invasion or crossing epithelial barriers
3. Evasion of host defense system through inhibition of:
   - phagocytic uptake via polysaccharide capsule (e.g. *S. pneumoniae*, *N. meningitidis*, *H. influenzae*)
   - surface proteins (e.g. *Staphylococcus*, *Streptococcus*)
4. Toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. *Clostridium*)
   - endotoxins are structural components of GN bacterial cell walls, and may be shed by live cells or released during cell lysis
5. Intracellular growth
   - obligate intracellular: Rickettsia, *Chlamydia*, *Chlamydophilia*
   - facultative intracellular: *Salmonella*, *Neisseria*, *Brucella*, *Mycobacteria*, *Listeria*, *Legionella*
6. Biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices such as IV catheters

## Table 1. Common Bacteria

| | Gram-Positive Bacteria | | Gram-Negative Bacteria | | Not Seen on Gram Stain | |
|---|---|---|---|---|---|---|
| | **Cocci** | **Bacilli (rods)** | **Diplococci** | **Bacilli (rods)** | **Acid Fast** | **Others** |
| **Aerobes** | *Staphylococcus*<br>*S. aureus*<br>*S. saprophyticus*<br>*S. epidermidis*<br>*S. lugdunensis*<br>*Streptococcus*<br>*S. pneumoniae*<br>*S. pyogenes* (GAS)<br>*S. agalactiae* (GBS)<br>*S. anginosis* group<br>*Enterococcus*<br>*E. faecalis* | *Bacillus*<br>*B. anthracis*<br>*Listeria*<br>*Nocardia* (modified acid-fast positive) | *Neisseria*<br>*N. meningiditis*<br>*N. gonorrhoeae*<br>*Moraxella*<br>*M. catarrhalis* | *Enterobacteriaceae*<br>*E. coli*<br>*Salmonella*<br>*Shigella*<br>*Campylobacter*<br>*Yersinia*<br>*Klebsiella*<br>*Legionella*<br>*Pseudomonas*<br>*Haemophilus*<br>*H. influenzae* | *Mycobacteria*<br>*M. tuberculosis*<br>*M. leprae*<br>*M. avium* complex | Obligative intracellular<br>*Rickettsiae*<br>*Chlamydia*<br>*C. trachomatis*<br>*Chlamydophila*<br>*C. pneumoniae*<br><br>No cell wall<br>*Mycoplasma*<br><br>Spirochaete (spiral)<br>*Treponema pallidum* |
| **Anaerobes** | *Peptostreptococcus*<br>*Cutibacterium (Propionibacterium)* acnes | *Clostridium*<br>*C. difficile*<br>*C. tetani*<br>*C. botulinum*<br>*C. perfringens* | | *Bacteroides*<br>*B. fragilis* | | |

## Table 2. Commensal Flora

| Site | Organisms |
|---|---|
| **Skin** | Coagulase-negative staphylococci, *Corynebacterium*, *C.* acnes, *Bacillus*, *S. aureus* |
| **Oropharynx** | Viridans group streptococci, *Haemophilus*, *Neisseria*, anaerobes (*Peptostreptococcus, Bacteroides, Veillonella, Fusobacterium, Actinomyces, Prevotella*) |
| **Small Bowel** | *E. coli*, anaerobes (low numbers) |
| **Colon** | *E. coli*, *Klebsiella*, *Enterobacter*, *Enterococcus*, anaerobes (*Bacteroides, Peptostreptococcus, Clostridium*) |
| **Vagina** | *Lactobacillus acidophilus*, viridans group streptococci, coagulase-negative staphylococci, facultative Gram-negative bacilli, anaerobes |

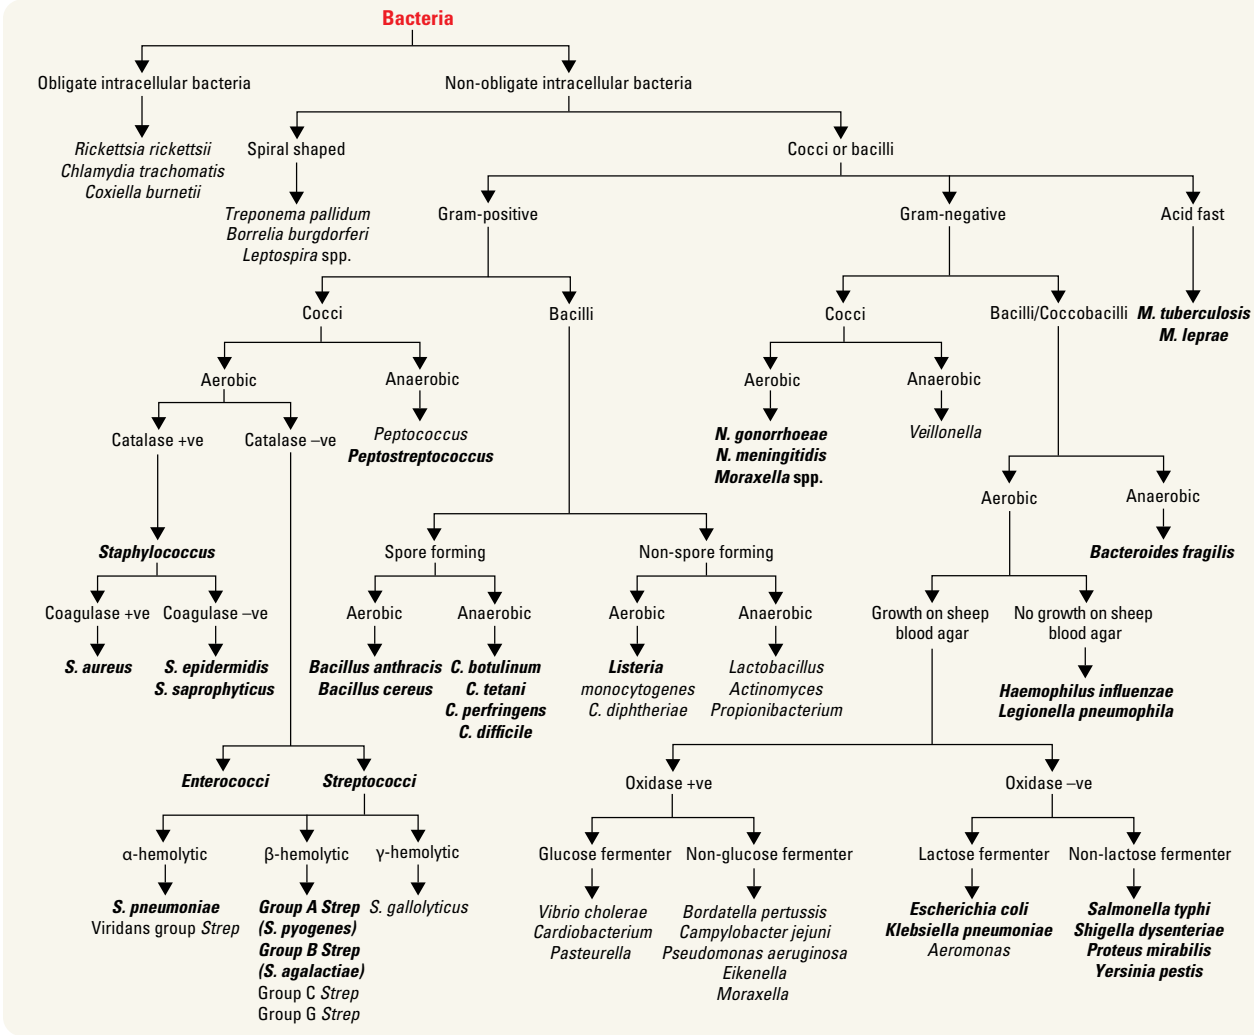

**Figure 2. Laboratory identification of bacterial species**

# Virology

## Viral Basics

- viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - infect cells and use host metabolic machinery to replicate
  - nucleic acid can be double stranded (ds) or single stranded (ss)
  - can be enveloped or naked
- virions are mature virus particles that can be released into the extracellular environment
- host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

## Viral Disease Patterns

1. acute infections (e.g. adenovirus)
   - host cells are lysed in the process of virion release
   - some produce acute infections with late sequelae (e.g. measles virus induced subacute sclerosing panencephalitis)
2. chronic infections (>6 mo): (e.g. HBV, HIV)
   - host cell machinery is used to produce and chronically release virions
3. latent infections
   - viral genome remains latent in host cell nucleus
   - can reactivate (e.g. HSV, VZV)

**Table 3. Common Viruses**

| Nucleic Acid | Enveloped | Virus Family | Major Viruses | Medical Importance |
|---|---|---|---|---|
| **dsDNA** | N | *Adenoviridae* | Adenovirus | URTI<br>Conjunctivitis<br>Gastroenteritis |

# Mycology

## Fungal Basics

- fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. moulds, i.e. filamentous fungi (multicellular with hyphae)
  3. dimorphic fungi (found as mould at room temperature but grow as yeast-like forms at body temperature)

**Table 4. Membrane and Cell Wall Compositions**

| | Membrane Sterol | Cell Wall |
|---|---|---|
| **Bacteria** | – | Peptidoglycan |
| **Human Cell** | Cholesterol | – |
| **Fungi** | Ergosterol | Chitin (complex glycopolysaccharide) |

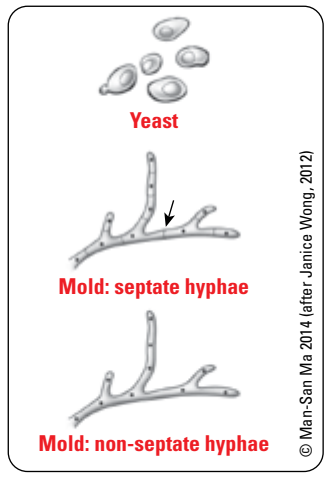

**Figure 4. Common fungus morphology**

## Mechanisms of Fungal Disease

- primary fungal infection by:
  - overgrowth of normal flora (e.g. *Candida* species)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

# Parasitology

## Parasite Basics

- **parasite**: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 24 and 25, ID37-38 for examples of clinically important parasites

**Table 5. Differences Between Protozoa and Helminths**

| Protozoa | Helminths |
|---|---|
| Unicellular | Multicellular |
| Motile trophozoite, inactive cyst | Adult → egg → larva |
| Multiplication | No multiplication in human host |
| Eosinophilia unusual | Eosinophilia (proportional to extent of tissue invasion)* |
| Indefinite life span | Definite life span |

*Adult Ascaris (roundworm) does not cause eosinophilia; migratory larval phases of Ascaris, however, cause high-grade eosinophilia

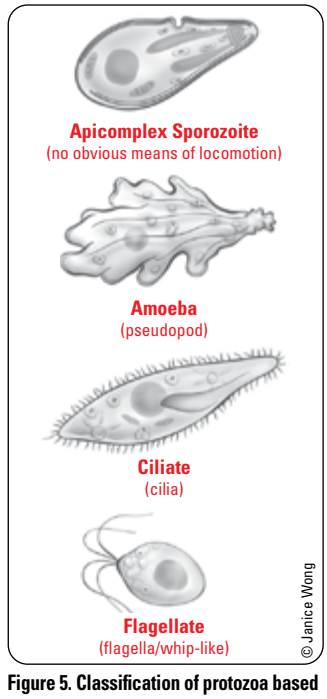

**Figure 5. Classification of protozoa based on movement**

## Characteristics of Parasitic Disease

- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

## Mechanisms of Parasitic Disease

1. Mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. Competition with host for resources (e.g. anemia in hookworm disease, vitamin B12 deficiency in diphyllobothriasis)
3. Cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. Inflammatory
   - acute hypersensitivity (e.g. pneumonitis in Loeffler's syndrome)
   - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
   - cytokine-mediated (e.g. systemic illness of malaria, disseminated strongyloidiasis)
5. Immune-mediated injury
   - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
   - immune complex (e.g. nephritis of malaria, schistosomiasis)

Parasite sampling may need to be repeated on a number of occasions before infection can be ruled out

# Transmission of Infectious Diseases

**Table 6. Mechanism of Transmission**

| Mechanism | Mode of Transmission | Examples | Preventative Measure |
|---|---|---|---|
| **Contact** | Direct physical contact, or indirect contact with a fomite | Skin-to-skin (MRSA)<br>Sexual (*N. gonorrhoeae*, *C. trachomatis*, HSV, HIV)<br>Blood-borne (HIV, HBV, HCV) | For patients in health care facilities:<br>Contact precautions<br>Barrier precautions<br>Safe needlestick/sharp practices |
| **Droplet/ Contact** | Respiratory droplets (>5 μm) can be projected short distances (≤2 m) and deposit on mucosal surfaces of the recipient (e.g. by coughing, sneezing, or talking); transmission can also occur by direct physical contact of respiratory fluids or indirect contact with a fomite contaminated with respiratory fluids | Influenza, mumps<br>*N. meningitidis*, *Bordetella pertussis* | For patients in health care facilities:<br>Contact/droplet precautions |
| **Airborne** | Airborne droplet nuclei (<5 μm) remain infectious over time and distance | *M. tuberculosis*, disseminated VZV, measles | For patients in health care facilities:<br>Airborne precautions |
| **Food/ Waterborne** | Ingestion of contaminated food or water | *V. cholerae*, *Salmonella*, HAV, HEV | Prophylactic vaccinations where available<br>Ensure clean food/water supply<br>For patients in health care facilities:<br>Contact precautions used for admitted patients with fecal incontinence when stool is unable to be contained in diapers |
| **Zoonotic** | Disease transmission from animals to humans either directly or via an insect vector | Animals (rabies, Q fever)<br>Arthropods (malaria, Lyme disease, West Nile virus) | Prophylactic medications, vaccinations<br>Protective clothing, insect repellent, mosquito nets, tick inspection |
| **Vertical** | Spread of disease from parent to offspring | Congenital syndromes (TORCH infections)<br>Perinatal (HIV, HBV, GBS) | Prenatal screening<br>Prophylactic treatment |

# Nosocomial Infections

- **definition**: infections acquired >48 h after admission to a healthcare facility OR within 30 d from discharge
- **risk factors**: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
  - patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

**Table 7. Common Nosocomial Infectious Agents**

| Bacteria | Characteristics | Manifestation | Investigations | Management |
|---|---|---|---|---|
| **Methicillin-Resistant *S. aureus* (MRSA)** | Gram-positive cocci | Skin and soft tissue infection<br>Bacteremia<br>Pneumonia<br>Endocarditis<br>Osteomyelitis | Admission screening culture from nares and peri-anal region identifies colonization<br>Culture of infection site<br>CXR | Contact precautions<br>For infection: vancomycin or daptomycin or linezolid<br>To decolonize: 2% chlorhexidine wash OD (+ rifampin + (doxycycline or TMP/SMX) + mupirocin cream bid to nares) x 7 d |
| **Vancomycin-Resistant *Enterococcus* (VRE)** | Majority are *E. faecium*<br>Resistant if minimum inhibitory concentration of vancomycin is ≥32 μg/mL | Rarely causes disease in healthy people<br>UTI<br>Bacteremia<br>Endocarditis<br>Meningitis | Rectal or perirectal swab OR stool culture for colonization<br>Culture of infected site | Contact precautions*<br>Ampicillin if susceptible<br>Otherwise, linezolid, tigecycline, or daptomycin depending on site of infection<br>No effective decolonization methods identified |
| ***Clostridium difficile* (*C. difficile*)** | Releases exotoxins A and B<br>Hypervirulent strain (NAP1/ B1/027) has been responsible for increase in incidence and severity | Fever, nausea, abdominal pain<br>Watery diarrhea<br>Pseudomembranous colitis<br>Severe: toxic megacolon<br>Risk of bowel perforation<br>Associated with antibiotic use<br>Leukocytosis | Stool PCR for toxin A and B genes<br>Stool immunoassay for toxins A and B (less sensitive than PCR)<br>AXR (may see colonic dilatation)<br>Sigmoidoscopy for pseudomembranes; avoid if known colonic dilatation | Contact precautions<br>Stop culprit antibiotic therapy (primarily fluoroquinolones and clindamycin)<br>Supportive therapy (IV fluids)<br>Empiric treatment with either vancomycin or fidaxomicin<br>If access to empiric treatment is limited, then metronidazole may be used<br>For fulminant *C. difficile* infection (previously called severe), oral vancomycin is used. IV metronidazole added to regimen if ileus present |
| **Extended Spectrum β-lactam Producers (ESBL producing** E. coli, K. *pneumoniae*) | Resistant to most β-lactam antibiotics except carbapenams e.g. penicillins, aztreonam,** and cephalosporins | UTI<br>Pulmonary infection<br>Bacteremia<br>Liver abscess in susceptible patients<br>Meningitis | Blood, sputum, urine, or aspirated body fluid culture<br>Imaging at infection site (CXR, CT, U/S) | Carbapenems or non-β-lactam antibiotics can be used for empiric therapy |

*The use of contact precautions for VRE varies depending on institutional policies. **Not available in Canada

# Respiratory Infections

## Pneumonia

• see Pediatrics, P83

### Definition
• infection of the lung parenchyma

### Etiology and Risk Factors
• impaired lung defenses
  ▪ poor cough/gag reflex (e.g. illness, drug-induced)
  ▪ impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  ▪ immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
• increased risk of aspiration
  ▪ impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
• no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

When *Klebsiella* causes pneumonia; see red currant jelly sputum

**3 As of *Klebsiella***
**A**spiration pneumonia
**A**lcoholics and diabetics
**A**bscess in lungs

**Table 8. Common Organisms in Pneumonia**

| Community-Acquired | Nosocomial | Aspiration | Immunocompromised Patients | Alcoholic |
|---|---|---|---|---|
| Typical Bacteria<br>*Streptococcus pneumoniae*<br>*Moraxella* catarrhalis<br>*Haemophilus influenzae*<br>*Staphylococcus aureus*<br>GAS<br>Atypical Bacteria<br>*Mycoplasma pneumoniae*<br>*Chlamydophila pneumoniae*<br>*Legionella pneumophila*<br>Viral<br>Influenza virus<br>Adenovirus | Enteric GNB (e.g. *E. coli*)<br>*Pseudomonas aeruginosa*<br>*S. aureus* (including MRSA) | Oral anerobes (e.g. *Bacteroides*)<br>Enteric GNB (e.g. *E. coli*)<br>*S. aureus*<br>Gastric contents (chemical pneumonitis) | *Pneumocystis jiroveci*<br>Fungi (e.g. *Cryptococcus*)<br>*Nocardia*<br>CMV<br>HSV<br>TB | *Klebsiella*<br>Enteric GNB<br>*S. aureus*<br>Oral anaerobes (aspiration)<br>TB |

*See **Pediatrics**, P84, Table for *Common Causes and Treatment of Pneumonia at Different Ages*

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger calibre and more vertical orientation of the right bronchus

### Clinical Feature
• cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
• elderly often present atypically; altered LOC is sometimes the only sign
• evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
• features of parapneumonic effusion (decreased air entry, dullness to percussion)
• complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

### Investigations
• pulse oximetry to assess severity of respiratory distress
• CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
• sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
• CXR ±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
• bronchoscopy ± washings for:
  ▪ (1) severely ill patients refractory to treatment and (2) immunocompromised patients

**Does This Patient Have Ventilator-Associated Pneumonia?**
JAMA 2007;297:1583-1593
**Study**: Systematic review of articles describing the precision and accuracy of clinical, radiographic, and laboratory data to diagnose bacterial ventilator-associated pneumonia, which is the most common and fatal nosocomial complication of intensive care.
**Results**: The presence of a new infiltrate on radiography with 2 or more of purulent sputum, fever, or increased white blood cell count increases the likelihood of ventilator-associated pneumonia (LR 2.8, 95% CI 0.97-7.9). Fewer than 50% neutrophils on the cell count of lower pulmonary secretions make ventilator-associated pneumonia unlikely (LR 0.05-0.10).
**Conclusions**: Routine bedside evaluation with radiographic information provides suggestive, but not definitive, evidence of ventilator-associated pneumonia. Clinicians need to consider additional tests to provide further evidence for ventilator-associated pneumonia.

### Treatment
• ABC, $O_2$, IV fluids, consider salbutamol (nebulized or MDI)
• determine prognosis and need for hospitalization and antibiotics

### Criteria for Hospitalization

**Table 9. CURB 65 Score – Pneumonia Clinical Prediction Tool**

| Component* | Measurement(s) | Points | Total Score | Mortality | Disposition |
|---|---|---|---|---|---|
| **Confusion** | Altered mental status | 1 | 0-1 | <5% | Can treat as outpatient |
| **Urea/BUN** | Urea >7 mmol/L or BUN >20 mg/dL | 1 | 2-3 | 5-15% | Consider hospitalization |
| **Respiratory Rate** | >30 breaths/min | 1 | 4-5 | 15-30% | Consider ICU |
| **Blood Pressure** | Systolic <90 or diastolic <60 mmHg | 1 | | | |
| **Age** | 65 or older | 1 | | | |

* A CRB-65 score may be applied in the community as its criteria depend on clinical assessment alone

**Table 10. IDSA/ATS Community Acquired Pneumonia Treatment Guidelines 2007**

| Setting | Circumstances | Treatment |
|---|---|---|
| **Outpatient** | Previously well<br>No antibiotic use in last 3 mo | β-lactam[1], Macrolide[2]<br>OR Doxycycline<br>OR Omadacycline (for adult use only; not intended in pediatric population) |
| | Comorbidities[3]<br>Antibiotic use in last 3 mo (use different class) | β-lactam[1] ± Macrolide[2]<br>OR Respiratory fluoroquinolone[4] |
| **Inpatient** | Ward | β-lactam[1] ± Macrolide[2]<br>OR Respiratory fluoroquinolone[4]<br>OR Omadacycline (for adult use only; not intended in pediatric population) |
| | ICU | β-lactam[1] + (Macrolide[2] OR Respiratory fluoroquinolone[4]) |

*Given different regional resistance patterns, therapy should be based on local epidemiology and site-specific recommendations
**Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified
1. **β-lactam**: cefotaxime, ceftriaxone, ampicillin-sulbactam
2. **Macrolide**: use azithromycin or clarithromycin
3. **Comorbidities**: chronic heart, lung, liver, or renal disease, DM, alcoholism, malignancy, asplenia, immunocompromised
4. **Respiratory fluoroquinolone**: moxifloxacin, gemifloxacin, levofloxacin
**IDSA**: Infectious Diseases Society of America
**ATS**: American Thoracics Society

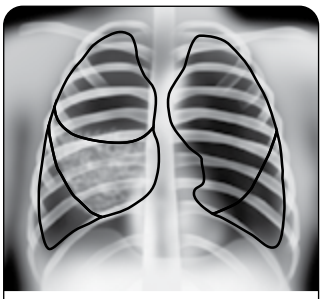

**Table 11. IDSA/ATS Hospital-Acquired (HAP) and Ventilator-Associated (VAP) Pneumonia Clinical Practice Guidelines 2016**

| Setting | Treatment |
|---|---|
| Clinically suspected **HAP** (non-VAP) with no increase in likelihood of MRSA and not at high risk of mortality | **One of**:<br>piperacillin-tazobactam<br>OR cefepime<br>OR levofloxacin<br>OR imipenem<br>OR meropenem |
| Clinically suspected **HAP** (non-VAP) with increasing likelihood of MRSA and not at high risk of mortality | **One of:**<br>piperacillin-tazobactam<br>OR cefepime or ceftazidime<br>OR levofloxacin or ciprofloxacin<br>OR imipenem or meropenem<br>OR aztreonam*****<br>**PLUS one of**:<br>vancomycin or linezolid for MRSA coverage |
| Clinically suspected **HAP** (non-VAP) with high risk of mortality or recipient of IV antibiotics in last 90 d | **Two of the following (avoid 2 β-lactams):**<br>piperacillin-tazobactam<br>OR cefepime or ceftazidime<br>OR levofloxacin or ciprofloxacin<br>OR imipenem or meropenem<br>OR aztreonam*****<br>OR amikacin or gentamicin or tobramycin<br>**PLUS either MRSA or MSSA coverage:**<br>MRSA: vancomycin or linezolid<br>OR MSSA: piperacillin-tazobactam, cefepime, levofloxacin, imipenem, meropenem |
| Clinically suspected **VAP** in units where empiric MRSA coverage and double antipseudomonal/ Gram-negative coverage are appropriate | **One of**:<br>β-lactam/β-lactamase inhibitor (piperacillin/tazobactam)<br>OR antipseudomonal cephalosporin (cefepime or ceftazidime)<br>OR antipseudomonal carbapenem (imipenem or meropenem)<br>OR monobactam (aztreonam*****)<br>**PLUS one of:**<br>antipseudomonal fluoroquinolone (ciprofloxacin or levofloxacin)<br>OR aminoglycoside (amikacin, gentamicin, or tobramycin)<br>OR polymyxins (colistin or polymyxin B)<br>**PLUS one of:**<br>vancomycin or linezolid for MRSA coverage |

**Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified
*** Available in Canada through special access**
Risk factors for mortality include need for ventilatory support due to pneumonia and septic shock
Risk factors for MDR VAP: prior IV antibiotic use within 90 d, septic shock at time of VAP, ARDS preceding VAP, 5+ d of hospitalization prior to VAP onset, acute renal replacement therapy prior to VAP onset
Risk factors for MDR HAP, MRSA VAP/HAP or MDR *Pseudomonas* VAP/HAP: Prior IV antibiotic use within 90 d
**Note**: Indications for MRSA coverage includes IV antibiotic treatment during the prior 90 d and treatment in a unit where prevalence of MRSA of *S. aureus* isolates is not known or is >20%
**Note**: These guidelines may be less applicable in Canada given lower rates of antibiotic resistance among common nosocomial pathogens

## Prevention

- Public Health Agency of Canada recommends the following
  - vaccine for influenza A and B annually for all ages ≥6 mo
  - pneumococcal polysaccharide vaccine (Pneumovax®) for all adults >65 yr and in younger patients 24 mo of age and older at high risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
  - pneumococcal conjugate vaccine (Prevnar-13®) for all children <5 yr, and for children and adolescents at high risk for invasive pneumococcal disease who are 5-17 yr and who have not previously received Prevnar-13® (CDC recommends giving Prevnar-13® to all adults at high risk for invasive pneumococcal disease)

Lobar Pneumonia

Bronchopneumonia

Interstitial Pneumonia

©Stuart Jantzen 2012

**Figure 6. Lobar, broncho, and interstitial pneumonia**

**Does This Adult Patient Have Pneumonia? From The Rational Clinical Examination**
JAMA 2009; http://www.jamaevidence.com/content/3485708
**Study**: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult community acquired pneumonia.
**Results**: The presence of fever or immunosuppression had a positive likelihood ratio (+LR) of 2, while a history of dementia had a +LR of 3; however, these traits are not confirmatory. The presence of an abnormality in any vital sign, including tachycardia, tachypnea, or fever had a +LR ranging from 2-4, which was not significantly affected by different cut-points. The absence of vital sign abnormality had a –LR ranging from 0.5-0.8. The combination of respiratory rate <30/min, heart rate <100/min, and temperature <37.8°C had a –LR of 0.18. Findings on chest exam raised the likelihood of diagnosis, but were uncommonly seen in studies. For example, presence of asymmetric respirations essentially confirmed the diagnosis, but was only present in 4% of patients. In patients with a clinical diagnosis, but normal radiograph, only ~10% will develop radiographic findings in 72 h.
**Conclusions**: Evidence suggests no single item on clinical history or physical exam is sufficient to rule in or out pneumonia without chest x-ray. Vital sign abnormalities were correlated with a diagnosis of pneumonia. Findings on chest exam significantly raised the likelihood of pneumonia, but were uncommonly seen in studies.

# Influenza

## Definitions and Etiology

- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: influenza A (H1N1), influenza A (H3N2) and influenza B
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

**Table 12. Difference Between Influenza Strains**

| | Influenza A | Influenza B |
|---|---|---|
| **Host(s)** | Humans, birds, mammals | Humans only |
| **Antigenic Drift** | Yes, new strains | Yes, new strains |
| **Antigenic Shift** | Yes, new subtypes | No |
| **Epidemics** | Yes | Yes |
| **Pandemics** | Yes | No |

## Clinical Feature

- incubation period 1-4 d and symptoms typically resolve in 7-10 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)
- severe disease more likely in the elderly, children, pregnant women, patients with immunocompromise, asthma, COPD, CVD, diabetes, and obesity

## Investigations

- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for RT-PCR (gold standard), or rapid antigen detection (DFA, direct fluorescent antigen) detection
- serology: rarely used for clinical management

## Treatment and Prevention

- primarily supportive unless severe infection or high-risk for complications
- neuraminidase inhibitors: oseltamivir (Tamiflu®) or zanamivir (Relenza®) for treatment and prophylaxis against types A and B
  - decreases duration (by ~1 d) and severity of symptoms if given within 48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- vaccine for influenza A and B viruses is recommended annually for all ages ≥6 mo
  - vaccine is reformulated each year to reflect circulating influenza A and B strains

## High Risk for Complications

- anyone who is hospitalized, patients with severe illness/chronic medical conditions, immunocompromised patients, children <2 yr, elders >65 yr, pregnant women or women ≥2 wk postpartum

**Beware! Do Not Confuse *H. influenzae* with Influenza Virus**

***H. influenzae***: a bacterium (Types A, B, C, D, E, F, refer to capsule)
**Influenza**: a virus (Types A and B refer to strain)

**Vaccines for Preventing Influenza in Healthy Adults**

Cochrane DB Syst Rev 2014;CD001269
**Study**: Meta-analysis of 90 RCTs and quasi-RCTs evaluating influenza vaccines compared to placebo in healthy individuals aged 16-65 yr.
**Results**: The preventative effect of inactivated influenza vaccine on healthy adults is small: 40 people would need a vaccination to avoid one influenza-like illness and 71 people would need a vaccination to prevent one case of influenza. 15.6% of unvaccinated versus 9.9% of vaccinated people developed influenza-like symptoms: of these participants, only 2.4% and 1.1%, respectively, developed laboratory-confirmed influenza. Vaccination had a modest effect on working days lost, but no effects on hospitalization or complications. The effectiveness of live aerosol vaccinations on healthy adults is similar to that of inactivated influenza vaccines: 46 people would need a vaccination to avoid one influenza-like illness.
**Conclusions**: Influenza vaccines have a very modest effect in reducing influenza-like illness and working days lost in the general population.

**Acute Myocardial Infarction after Laboratory-Confirmed Influenza Infection**

NEJM 2018;378:345-53.
**Objective**: To investigate the association between laboratory-confirmed influenza infection and acute MI.
**Methods**: Self-controlled case-series. Risk interval defined as first 7 d after respiratory specimen collection and control interval as 1 yr before and 1 yr after the risk interval.
**Results**: Increased incidence ratio of an admission for acute MI during risk interval vs. control interval (6.05, 95% CI 3.86-9.50). No increased incidence after 7 d. Increased incidence ratios for acute MI within 7 d after detection of influenza B (10.11, 95% CI 4.37-23.38), influenza A (5.17, 95% CI 3.02-8.84), and respiratory syncytial virus (3.51, 95% CI 1.11-11.12).
**Conclusions**: Significant association between respiratory infections, especially influenza, and acute MI.

# Skin and Soft Tissue Infections

## Cellulitis

### Definition
- acute infection of the skin principally involving the dermis and subcutaneous tissue

### Etiology
- common causative agents: β-hemolytic streptococci (by far the most common cause of non-purulent cellulitis) and occasionally *S. aureus* or *S. lugdunensis*
- immunocompromised patients or water exposure: may also include Gram-negative rods and fungi
- bite wounds: consider skin of "bitee" and mouth of "biter"
- risk factors
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema, DM, cracked skin in feet/toes (tinea pedis)

,
### Clinical Feature
- pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

### Investigations
- CBC and differential, blood C&S if febrile
- skin swab ONLY if open wound with pus

### Treatment
- consult local guidelines for appropriate antibiotic therapy
- antibiotics: cephalexin (broader coverage if risk factors for Gram-negative rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- if MRSA is suspected, empiric coverage for MRSA may be considered (see *A Simplified Look at Antibiotics*, ID44)
- limb rest and elevation may help reduce swelling

## Necrotizing Fasciitis

### Definition
- life- and limb-threatening infection of the deep fascia characterized by rapid spread

### Etiology
- two main forms
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus*, *Bacteroides*, *Enterobacteriaceae*)
  - Type II: monomicrobial infection with GAS, and less commonly *S. aureus*

### Clinical Feature
- pain out of proportion to clinical findings and beyond border of erythema
- edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
- infection spreads rapidly
- patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae

### Investigations
- clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum CK (elevated CK usually means myonecrosis – a late sign)
- plain film x-ray (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

### Treatment
- resuscitation with IV fluids
- emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): cefazolin (or cloxacillin) + clindamycin IV; with confirmed GAS infection, penicillin G + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

# Acquired Oral Lesions

### Etiology
- Infection (e.g. candidiasis, gonococcal infection), HSV
- Malignancy (e.g. adenocarcinoma, leukoplakia)
- Poor oral hygiene (e.g. caries, periodontal disease)
- Trauma (e.g. abuse)
- Toxic ingestion
- Xerostomia (e.g. age, medications)
- Systemic diseases (e.g. lichen planus, Behçet disease)

**Table 13. Comparison between Oral Infection vs Oral Carcinoma**

| | Oral Candidiasis | Oral Squamous Cell Carcinoma |
|---|---|---|
| **Risk Factors** | Antibiotics, chemotherapy, radiation therapy<br>Immunocompromise<br>Age – infants, older adults with dentures | Tobacco use (smoked and smokeless)<br>Betel use<br>Alcohol<br>HPV, especially HPV-16 |
| **Morphology** | Pseudomembranous: confluent, white patches or plaques, can be wiped off with a gauze, exposing an erythematous base<br><br>Atrophic candidiasis: red patches localized mainly to the palate and dorsum of the tongue | A lesion of three or more weeks duration:<br>• Red or red and white lesion<br>• Ulcer<br>• Lump<br>• Especially when in combination or if indurated (firm on palpation) |
| **Diagnosis** | Medical and physical | Biopsy and histopathologic examination |
| **Treatment** | Topical antifungal | Referral to ENT |

# Gastrointestinal Infections

- see Gastroenterology, G15 and Pediatrics, P37

# Traveller's Diarrhea

- see Gastroenterology, G18

# Chronic Diarrhea

- see Gastroenterology, G19

# Peptic Ulcer Disease (*H. pylori*)

- see Gastroenterology, G11

# Bone and Joint Infections

## Septic Arthritis

### Definition
- infection of one of more joints by pathogenic microbes

**Medical Emergency**
Septic arthritis is a medical emergency! If untreated, rapid joint destruction will occur

### Routes of Infection
- hematogenous
  - contiguous osteomyelitis common in children
- direct inoculation via skin/trauma
- iatrogenic (surgery, arthroscopy, arthrocentesis)

### Etiology
- gonococcal
  - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
  - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  - *Streptococcus* species (Group A and B)

**Disseminated Gonococcal Infection Triad**
- Migratory arthralgias
- Tenosynovitis next to inflamed joint
- Pustular skin lesions

  - Gram-negatives: affect neonates, elderly, injection drug users, immunocompromised
  - *S. pneumoniae*: affects children
  - *Kingella kingae*: affects children aged <4 yr of age
  - *Haemophilus influenzae* type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
  - *Salmonella* spp.: characteristic of sickle cell disease
  - coagulase-negative *Staphylococcus* species: prosthetic joints
- if culture negative: partially-treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as *Borrelia* spp. (Lyme disease) or *Tropheryma whipplei* (Whipple's disease), and non-infectious causes

### Risk Factors
- gonococcal
  - age (<40 yr), multiple partners, unprotected intercourse, MSM
- non-gonoccocal
  - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
  - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  - prosthetic joints/recent joint surgery
  - underlying joint disease (rheumatoid arthritis, osteoarthritis)
  - immunocompromise (DM, chronic kidney disease, alcoholism, cirrhosis)
  - loss of skin integrity (cutaneous ulcer, skin infection)
  - age >80 yr

### Clinical Feature of Gonococcal Arthritis
- two forms (although often overlap):
  - septic arthritis form- local symptoms in involved joint (swelling, warmth, pain, inability to weight bear, decreased ROM)
  - bacteremic form- systemic symptoms of fever, malaise, chills

### Clinical Feature of Non-Gonoccocal Arthritis
- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills; in children, refusal to weight bear
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

### Investigations
- consider rheumatologic causes for monoarthritis (see Rheumatology, RH3)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15,000/mm$^3$: likelihood of infection increases with increasing WBCs), PMNs >90%, culture positive
  - growth of *N. gonorrhoeae* from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Intra-articular steroids are contraindicated until septic arthritis has been excluded

### Treatment
- medical
  - empiric IV antibiotics: specific choice depends on clinical scenario and local guidelines; for most adults, cefazolin ± vancomycin is reasonable; for fully vaccinated children, cefazolin or cloxacillin IV unless MRSA is a consideration – delay may result in joint destruction
  - Gram stain and cultures guide subsequent treatment
  - gonococcal: ceftriaxone (+ azithromycin for concurrent treatment of *C. trachomatis*), 7 d of therapy usually sufficient
  - non-gonococcal: antibiotics against *Streptococcus* spp. (2-3 wk IV f/b PO), S. aureus (4 wk IV minimum), or GNB (4 wk, newer evidence suggest early switch to PO is safe and effective)
- surgical intervention if (see Orthopedic Surgery, OR11)
  - would consider surgical intervention on all cases of septic arthritis if possible
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement, especially in pediatric population
  - prosthetic joint
  - daily joint aspirations until culture sterile
  - physiotherapy

### Prognosis
- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

# Diabetic Foot Infections

### Etiology
- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: *Streptococcus* spp., *S. aureus*
- organisms in moderate/severe infection: polymicrobial with aerobes *(S. aureus, Streptococcus, Enterococcus*, GNB) and anaerobes (*Peptostreptococcus, Bacteroides, Clostridium*)

### Clinical Feature
- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, or history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) OR the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

### Investigations
- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI/bone scan if high clinical suspicion
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

### Treatment
- mild to moderate: cefazolin or cephalexin
- severe: options include- 1. ceftriaxone + metronidazole; 2. piperacillin/tazobactam ± vancomycin; 3. meropenem ± vancomycin
- optimize glycemic control, pressure offloading, wound care, consider revascularization

This is empiric treatment, and specific treatment needs to be adjusted based on culture and response to therapy

**Does this Patient with Diabetes have Osteomyelitis of the Lower Extremity?**
JAMA 2008;299:806-813
**Study**: Systematic literature review. 21 studies.
**Population**: 1027 adult patients with DM being investigated for osteomyelitis.
**Intervention**: Various aspects of history, physical exam, laboratory tests, and diagnostic imaging studies versus bone biopsy.
**Primary Outcome**: Diagnostic utility.
**Results**: No studies examined any part of history taking. Temperature, ulcer characteristics (erythema, swelling, purulence), elevated WBC, skin swabs, and soft tissue cultures were not useful. Nuclear imaging has poor specificity for osteomyelitis (62%-88.5%), and MRIs have greater accuracy in detecting osteomyelitis.

# Osteomyelitis

- see Orthopedic Surgery, OR10

# Cardiac Infections

## Infective Endocarditis

### Definition
- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

### Risk Factors and Etiology
- predisposing conditions
  - high risk: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - low/no risk: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, ischemic heart disease, previous CABG
  - opportunity for bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
- frequency of valve involvement MV >> AV > TV > PV
  - but in 50% of IVDU-related IE the tricuspid valve is involved

**Table 14. Microbial Etiology of Infective Endocarditis Based on Risk Factors**

| Native Valve | Intravenous Drug Users (IVDU) | Prosthetic Valve (recent surgery <2 mo) | Prosthetic Valve (remote surgery >2 mo) |
|---|---|---|---|
| ***Streptococcus*[1] (36%)** | ***S. aureus* (68%)** | ***S. aureus* (36%)** | ***Streptococcus* (20%)** |
| ***S. aureus* (28%)** | ***Streptococcus* (13%)** | ***S. epidermidis* (17%)** | ***S. aureus* (20%)** |
| ***Enterococcus* (11%)** | *Enterococcus* | Other | ***S. epidermidis* (20%)** |
| *S. epidermidis* | GNB | *Enterococcus* | ***Enterococcus* (13%)** |
| GNB | *Candida* | GNB | Other[2] |
| Other[2] | Other[3] | Other[2] | |

Organisms in bold are the most common isolates
1. *Streptococcus* includes mainly viridans group streptococci
2. Other includes less common organisms such as:
   - *Streptococcus gallolyticus* (previously known as *S. bovis*; usually associated with underlying GI malignancy, cirrhosis)
   - Culture-negative organisms including nutritionally-deficient streptococci, HACEK, *Bartonella, Coxiella, Chlamydia, Legionella, Brucella*
   - *Candida*
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = *Pseudomonas*, saliva = oral flora, toilet water = GI flora)

## Clinical Feature

- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute MR, AR)
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), headache (mycotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler's nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth's spots (retinal hemorrhage with pale centre)

**Clinical Features of Infective Endocarditis**

**FROM JANE**
**F**ever
**R**oth's spots
**O**sler's nodes
**M**urmur
**J**aneway lesions
**A**nemia
**N**ail-bed hemorrhages (i.e. splinter hemorrhages)
**E**mboli

## Diagnosis

- Modified Duke Criteria
  - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  - possible diagnosis if: 1 major + 1 minor, OR 3 minor

**Table 15. Modified Duke Criteria**

| Major Criteria (2) |
|---|
| 1. Positive blood cultures for IE<br>• Typical microorganisms for IE from 2 separate blood cultures (*Streptococcus viridans*, HACEK group, *Streptococcus gallolyticus* (previously known as *S. bovis*), *Staphylococcus aureus*, community-acquired enterococci) OR<br>• Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart OR<br>• All of 3 or a majority of 4 or more separate blood cultures, with first and last drawn >1 h apart OR<br>• Single positive blood culture for *Coxiella burnetii* or antiphase I IgG antibody titer >1:800<br>2. Evidence of endocardial involvement<br>• Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve); and new valvular regurgitation (insufficient if increase or change in preexisting murmur) |
| **Minor Criteria (5)** |
| 1. Predisposing condition (abnormal heart valve, IVDU)<br>2. Fever (38.0°C/100.4°F)<br>3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions<br>4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler's nodes, Roth's spots<br>5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE |

## Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48-72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), urea/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

**TEE** transesophageal echo
**TTE** transthoracic echo

### Treatment
- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment unless patient is septic
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken. Generally, *S. aureus*, coagulase-negative staphylococcus (CNST), and Gram-negative coverage is important
    - first line empiric treatment for native valve: vancomycin + gentamicin OR ceftriaxone
    - first line empiric treatment for prosthetic valve: vancomycin + gentamicin + rifampin
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and susceptibilities
  - monitor for complications of IE (e.g. HF, conduction block, new emboli) and complications of antibiotics (e.g. renal disease)
  - post treatment prophylaxis only recommended for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue
- dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if truly penicillin-allergic
- skin/soft tissue: cephalexin single dose 30-60 min prior; clindamycin if truly penicillin-allergic (modify based on etiology of skin/soft tissue infection)
- surgical
  - most common indication is refractory CHF
  - other indications include: valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, Staphylococci on a prosthetic valve

### Prognosis
- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status
- mortality: prosthetic valve IE (25-50%), non-IVDU *S. aureus* IE (30-45%), IVDU *S. aureus* or streptococcal IE (10-15%)

# CNS Infections

## Meningitis

- see Pediatrics, P57

### Definition
- inflammation of the meninges

### Etiology

**Table 16. Common Organisms in Meningitis**

| Bacterial | | | Viral | Fungal | Other |
|---|---|---|---|---|---|
| **Age 0-4 wk** | **Age 1-3 mo** | **Age >3 mo** | | | |
| GBS<br>*E. coli*<br>*L. monocytogenes*<br>*Klebsiella* | GBS<br>*E. coli*<br>*S. pneumoniae*<br>*N. meningitidis*<br>*H. influenzae* | *S. pneumoniae*<br>*N. meningitidis*<br>*L. monocytogenes*<br>(age >50 and comorbidities) | HSV-1, 2<br>VZV<br>Enteroviruses<br>Parechoviruses<br>West Nile | *Cryptococcus*<br>*Coccidioides* | Lyme disease<br>Neurosyphilis<br>TB |

### Risk Factors
- lack of immunization against *H. influenzae* type b, *S. pneumoniae*, and *N. meningitidis* in children
- most cases of bacterial meningitis are due to hematogenous spread from a mucosal surface (nasopharynx)
- direct extension from a parameningeal focus (otitis media, sinusitis) less common
- penetrating head trauma or iatrogenic
- anatomical meningeal defects – CSF leaks
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

### Clinical Feature
- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, headache, neck stiffness, confusion, lethargy, altered level of consciousness, seizures, focal neurological signs, nausea/vomiting, photophobia, papilledema
- petechial rash in meningococcal meningitis (purpura fulminans), seen more frequently on trunk or lower extremities

**Corticosteroids for Acute Bacterial Meningitis**
Cochrane DB Syst Rev 2015;CD004405
**Objectives**: To examine the effect of adjuvant corticosteroid therapy vs. placebo on mortality, hearing loss, and neurological sequelae with acute bacterial meningitis.
**Methods**: RCTs of corticosteroids for acute bacterial meningitis.
**Results**: 25 studies, 4121 participants. Corticosteroids were associated with non-significant mortality reductions (RR 0.90, 95% CI 0.80-1.01). Corticosteroids were associated with lower rates of hearing loss (RR 0.74, 95% CI 0.63-0.87) and neurological sequelae (RR 0.83, 95% CI 0.69-1.00). Corticosteroids were associated with increase in recurrent fever (RR 1.27, 95% CI 1.09-1.47).
**Conclusions**: Corticosteroids significantly reduced hearing loss and neurological sequelae, but did not reduce mortality. Data supports use in high-income countries but no benefit in low-income countries.

**Brudzinski's Sign**
Passive neck flexion causes involuntary flexion of hips and knees

**Kernig's Sign**
Resistance to knee extension when hip is flexed to 90°

**Jolt Accentuation of headache**
Headache worsens when head turned horizontally at 2-3 rotations; more sensitive than Brudzinski's and Kernig's

### Investigations
- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
  - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
  - AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
  - PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
  - West Nile virus serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

**Table 17. Typical CSF Profiles for Meningitis**

| CSF Analysis | Bacterial | Viral |
|---|---|---|
| **Glucose (mmol/L)** | Decreased | Normal |
| **Protein (g/L)** | Markedly Increased | Increased |
| **WBC** | 500-10,000/μL | 10-500/μL |
| **Predominant WBC** | Neutrophils | Lymphocytes |

### Treatment
- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
  - age ≤28 d: ampicillin + cefotaxime
  - age 29 d-3 mo: cefotaxime + vancomycin
  - age >3 mo: ceftriaxone + vancomycin
    - add ampicillin IV if risk factors for infection with *L. monocytogenes* present: age >50, alcoholism, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
  - continue in those patients with proven pneumococcal meningitis
  - not recommended for patients with suspected bacterial meningitis in some resource-limited countries
  - not recommended for neonatal meningitis

### Prevention
- see Pediatrics, P4
- immunization
  - children: immunization against *H. influenzae* type B (Pentacel®), *S. pneumoniae* (Synflorix®, Prevnar-13®), *N. meningitidis* (Menjugate®, Menactra®, Nimenrix®, Menveo®, Bexsero®)
  - adults: immunization against *N. meningitidis* in selected circumstances (outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with *H. influenzae* type B should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with *N. meningitidis*; meningococcal vaccines are also recommended for post-exposure prophylaxis for close contacts and in outbreak control

### Prognosis
- complications
  - death, headache, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness
- mortality
  - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

## Encephalitis

### Definition
- inflammation of the brain parenchyma

### Etiology
- identified in only 40-70% of cases
  - when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, parechoviruses, West Nile and other arboviruses, influenza and other respiratory viruses, HIV, mumps, measles, rabies, polio
  - bacteria: *L. monocytogenes*, *mycobacteria*, spirochetes (Lyme, syphillis), *Mycoplasma pneumoniae*
  - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
  - fungi: e.g. *Cryptococcus*
  - post-infectious (e.g. acute disseminated encephalomyelitis [ADEM])
  - auto-antibody mediated encephalitis
    - anti-N-methyl-D-aspartate (NMDA) receptor encephalitis most common
    - in adults, most autoantibody-mediated encephalitis cases are associated with malignancy

**CSF Gram Stain Findings**
- *S. pneumoniae* – GP diplococci
- *N. meningitidis* – GN diplococci
- *H. influenzae* – Pleiomorphic GN coccobacilli
- *L. monocytogenes* – GP rods

**Does this Adult Patient Have Acute Meningitis? From The Rational Clinical Examination**
JAMA 2009; http://www.jamaevidence.com/content/3482857
**Study**: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult meningitis.
**Results**: In retrospective studies, sensitivity for headache was 68%, and 52% for nausea and vomiting. Sensitivity for physical exam findings is similarly low (fever: 87%, neck stiffness: 80%, altered mental status: 69%). Sensitivity for the combination of the classic triad of fever, neck stiffness, and altered mental status was 46%. In prospective studies, sensitivity of headache was 92%, while sensitivity of nausea/vomiting could not be pooled, and ranged from 32-70%. Brudzinski's and Kernig's signs had a sensitivity of 5% and Kernig's sign only 5-9%. Jolt accentuation had a sensitivity of 97%.
**Conclusions**: Data were heterogeneous, and lacked standardization of clinical exams. No single item on clinical history or physical exam was sufficient to rule out meningitis, including Kernig's and Brudzinski's signs, or the absence of the classic triad of fever, neck stiffness, and altered mental status meningitis. Jolt accentuation has high sensitivity, but further research is needed. LP may be performed safely without CT head in patients without altered LOC, no recent seizure, no history of CNS disease, not immunocompromised, and <60 yr.

**Public Health Agency of Canada Indications for Adult Immunization**

**Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®)**
- >65 yr (option to also give pneumococcal conjugate vaccine; if so, to give polysaccharid vaccine 8 wk after conjugate vaccine)

**Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®) and Pneumococcal Conjugate Vaccine**
- Chronic cardiovascular/respiratory/hepatic/renal disorders, asplenia, sickle cell, or immunosuppression (polysaccharide vaccine to be given 8 wk after pneumococcal conjugate vaccine)

**Meningococcal Quadrivalent Vaccine (Menactra® or Menomune®)**
- Healthy young adults
- Asplenia
- Travellers to high-risk areas
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

**Multicomponent Meningococcal Serogroup B Vaccine (Bexsero®)**
- Asplenia
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency, or acquired terminal complement deficiency through receipt of eculizumab

### Pathophysiology
- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
  - associated with HSV-1, less likely caused by HSV-2
- influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

### Clinical Feature
- constitutional: fever, chills, malaise, nausea/vomiting
- meningeal involvement (meningoencephalitis): headache, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
  - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioural disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behavioural disturbances
  - rare complication: development of encephalopathy and Kluver-Bucy syndrome characteristics 1 mo after completion of treatment for HSV encephalopathy

### Investigations
- CSF: opening pressure, cell count and differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, M. *pneumoniae*, and selectively for other less common etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rabies, *Bartonella henselae*)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges

### Treatment
- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behaviour, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes ("meningoencephalitis")

**Bortezomib for Treatment of Therapy-Refractory anti-NMDA Receptor Encephalitis**
Neurology 2017;88(4):366-70.
**Objective**: To assess therapeutic potential of the plasma-cell-depleting proteasome inhibitor bortezomib in severe and therapy-refractor cases of anti-NMDA receptor encephalitis.
**Methods**: 5 severely affected patients with anti-NMDA receptor encephalitis with delayed treatment response or resistance to standard immunosuppressive and B-cell-depleting drugs were treated with 1-6 cycles of 1.3 mg/m2 bortezomib. Monitored for adverse events.
**Results**: 4 out of 5 patients showed clinical improvement or disease remission, accompanied by decline of anti-NMDA receptor antibodies. Associated with acceptable safety profile.
**Conclusions**: Bortezomib may be a promising escalation therapy in patients with severe and therapy-refractor anti-NMDA receptor encephalitis (Class IV evidence).

## Generalized Tetanus

- see Pediatrics, P4

### Etiology and Pathophysiology
- caused by *Clostridium* tetani: motile, spore forming, anaerobic Gram-positive *bacillus*
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, nonsterile surgeries or deliveries)
- upon inoculation, spores transform into *C. tetani* bacilli that produce tetanus toxin
  - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

### Clinical Feature
- generalized tetanus
  - initially present with painful spasms of masseters (trismus or "lockjaw")
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
  - diaphoresis, tachycardia, HTN, fever as illness progresses

### Investigations
- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, creatine kinase (CK) may be elevated

### Treatment

- stop toxin production
  - wound debridement to clear necrotic tissue and spores
  - antimicrobial therapy: IV metronidazole; IV penicillin G is an effective alternative
- neutralize unbound toxin with tetanus immune globulin (TIg)
- supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket
- control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

Antimicrobial therapy (e.g. metronidazole) may fail to treat *C. tetani* unless adequate wound debridement is performed

### Prevention

- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see Pediatrics, P4 and Emergency Medicine, ER17)

## Rabies

### Definition

- acute progressive encephalitis caused by RNA virus (genus *Lyssavirus* of the Rhabdoviridae family)

### Etiology and Pathophysiology

- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  - almost all cases due to bites
  - animals can be carriers for several days before manifest signs of disease
- virus travels via retrograde axonal transport from PNS to CNS
- virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
  - infected animal can transmit rabies virus as soon as it shows signs of disease

### Clinical Feature

- five stages of disease

1. incubation period
   - 1-3 mo on average (can range from days to years)
2. prodrome (<1 wk)
   - low-grade fever, malaise, anorexia, nausea/vomiting, headache, sore throat
   - pain, pruritus, and paresthesia may occur at wound site
   - once prodromal symptoms develop, there is rapid, irreversible progression to death
     - progression from prodrome to coma and death may occur without an intervening acute neurologic syndrome
3. acute neurologic syndrome: 2 types (<1 wk)
   a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia, hypersalivation, fever, seizures
     - painful pharyngeal spasms on encountering gust of air or swallowing water cause aerophobia and hydrophobia, respectively

   b. paralytic: quadriplegia, loss of anal sphincter tone, fever
4. coma
   - complete flaccid paralysis, respiratory, and cardiovascular failure
5. death (within days to weeks of initial symptoms)

### Investigations

- purpose of diagnosis by investigations is to limit patient contact with others and to identify others exposed to the infectious source
- ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, serum, CSF
- post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion bodies in neurons)

### Treatment

- post-exposure prophylaxis depends on regional prevalence and circumstances surrounding injury
- mandatory to report animal bite/contact that may result in rabies to Public Health Authority
- if not previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water
  - passive immunization: rabies immunoglobulin (RIG) infiltrated into wound site, with any remaining volume administered IM in anatomical site distant from vaccine administration. Due to variable response rates, vaccine should not be administered into gluteal muscle
  - active immunization: inactivated human diploid cell rabies virus vaccine (HDCV) – series of 4 shots post-exposure on days 0, 3, 7 and 14. Vaccine administered into deltoid

- if previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water
  - two doses of HDCV into deltoid on days 0 and 3
  - no RIG administered
- treatment is supportive once victim manifests signs and symptoms of disease

### Prevention
- pre-exposure vaccination
  - recommended for high risk persons: laboratory staff working with rabies, veterinarians, animal and wildlife control workers, long-term travellers to endemic areas

# Systemic Infections

## Sepsis and Septic Shock

- see Respirology, R30

### Definitions
- bacteremia: bacteria in blood from primary bloodstream infection or secondary to infection of another body system
- sepsis: severe organ dysfunction resulting from dysregulated host response to infection
  - organ dysfunction identified via acute change in SOFA score >2 points
  - qSOFA score used initially to screen patients for suspected sepsis using three criteria:
    1. respiratory rate >22/min
    2. systolic BP <100 mmHg
    3. altered mentation (GCS <15)
- septic shock: subset of sepsis with circulatory and cellular/metabolic dysfunction; clinically defined in cases where despite adequate volume resuscitation there is both:
  1. persistent hypotension requiring vasopressors to maintain MAP >65 mmHg AND
  2. serum lactate >2 mmol/L

SOFA score >2 = 10% mortality risk in patient with suspected infection
Hospital mortality with septic shock >40%

**qSOFA score**
1. respiratory rate >22/min
2. systolic BP <100 mmHg
3. altered mentation (GCS <15)

### Pathophysiology
- causative agents are identified in only 50-70% of cases
- when organisms are identified, Gram-positive and Gram-negative organisms are the cause in 90% of cases
- bacteremia → local immune response → pro-inflammatory cytokine release → spread of immune response beyond local environment → unregulated, exaggerated systemic immune response → vasodilation and hypotension → distributive shock and reduced $O_2$ delivery to tissues → anaerobic metabolism and lactic acid production → metabolic acidosis → multiple organ failure

### Clinical Feature
- history: symptoms and signs specific to an infectious source- e.g. cough, headache, dysuria, purulent exudate, rash
- general symptoms of infection: fever, chills, pain, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
- physical: abnormal vitals (e.g. fever, tachypnea, tachycardia, hypotension), flushed skin, altered mental status, local signs of infection(e.g. pharyngitis, septic arthritis, neck stiffness, skin wounds/ulcers, or murmurs)

**The Third International Consensus**
Definitions for Sepsis and Septic Shock (Sepsis-3) in 2016 re-defined sepsis using the Sequential Organ Failure Assessment (SOFA) score for diagnosis and Quick-SOFA (qSOFA) for screening of end-organ failure. The terms severe sepsis and systemic response inflammatory response syndrome (SIRS) are no longer part of the sepsis definition.

### Investigations
- CBC and differential, electrolytes, urea, creatinine, liver enzymes, ABG, lactate, INR, PTT, troponin, blood C&S x2, urinalysis, urine C&S, and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)
- nasopharyngeal swab/stool/sputum cultures, throat swabs, genital swab, LP as indicated

### Treatment (see Respirology, R30)
- respiratory support: $O_2$ ± intubation
- cardiovascular support: IV fluids ± blood transfusion + vasopressors + ICU
- IV antibiotics (empirical, depends on suspected source)
  - start with broad spectrum antibiotics (e.g. piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant Gram-negatives or vancomycin for MRSA)
  - narrow once susceptibilities are known
- source control: procedure to control focus of infection (catheter removal, abscess drainage)
- hydrocortisone IV in patients with septic shock unresponsive to fluid resuscitation and vasopressors

# Leprosy (Hansen's Disease)

### Etiology
- *Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

### Clinical Feature
- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  - i. paucibacillary "tuberculoid" leprosy (intact cell-mediated immune response)
    - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
    - may be self-limited, stable, or progress over time to multibacillary "lepromatous" form
  - ii. multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
    - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  - iii. borderline leprosy
    - lesions and progression lies between tuberculoid and lepromatous forms

### Investigations
- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

### Treatment (WHO Treatment Regimens)
- paucibacillary: dapsone daily + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampicin, ofloxacin, and minocycline
- multibacillary: dapsone + rifampin monthly + clofazimine monthly x 12 mo AND low dose clofazimine once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed or dying bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

### Prognosis
- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune reactions

# Lyme Disease

**BAKE a Key Lyme Pie**

**B**ell's palsy
**A**rthritis
**K**ardiac block
**Lyme**
**E**rythema chronicum migrans

### Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (N. America), *B. garinii, B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- in Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment

### Clinical Feature
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, headache, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) at site of tick bite
- stage 2 (early disseminated stage: weeks post-infection)
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronicum atrophicans (due to *B. afzelii*)
  - neurologic: encephalopathy, meningitis, neuropathy

### Investigations
- order Public Health Lab approved Lyme disease testing and interpret results on basis of symptoms

### Prevention
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- doxycycline prophylaxis within 72 h of removal of an engorged *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks ≥20%) for patients >8 yr who are not pregnant or lactating

### Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

## Toxic Shock Syndrome

### Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

### Risk Factors
- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or Cesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

### Clinical Feature and Investigations
- acute onset
- Staphylococcal TSS
  - T >38.9°C
  - sBP <90 mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
- Streptococcal TSS
  - sBP <90 mmHg
  - isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  - ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

### Treatment
- supportive care, fluid resuscitation, surgical debridement of infected tissue
- Streptococcal: IV penicillin and clindamycin and ± IVIg
- Staphylococcal: for methicillin-susceptible *S. aureus*: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d

## Cat Scratch Disease

### Etiology
- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

### Clinical Feature
- skin lesion appears 3-10 d post-inoculation
- may be followed by fever, tender regional lymphadenopathy
- in some patients, organism may disseminate causing fever of unknown origin, hepatosplenomegaly, retinitis, encephalopathy, infective endocarditis, uveitis
- usually self-limited

### Investigations
- serology, PCR, lymph node biopsy

### Treatment
- the disease may be self-limited but treatment is recommended by the Infectious Disease Society of America with a 5 d course of azithromycin for immunocompetent patients with mild to moderate illness
- needle aspiration of painful suppurative lymph nodes may hasten the relief of symptoms
- combination therapy consisting of doxycycline or azithromycin plus rifampin often used for disseminated disease (neuroterinitis, hepatosplenic involvement)

## Rocky Mountain Spotted Fever

### Etiology
- *Rickettsia rickettsii*: obligate intracellular Gram-negative organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks
- organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
- can cause widespread vasculitis leading to headache, and CNS changes; can progress to death if treatment is delayed

### Clinical Feature
- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, headache, myalgia, nausea/vomiting, anorexia
- macular rash appearing on day 2-4 of fever
  - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  - occasionally "spotless" (10% of patients)

### Investigations
- skin biopsy and serology (indirect fluorescent antibody test)

### Treatment
- doxycycline, usually 5-7 d (treat for 3 d after defervescence)

## West Nile Virus

### Epidemiology
- virus has been detected throughout the United States and much of southern Canada (Ontario and Manitoba)
- overall case-fatality rates in severe cases is ~10%

### Transmission
- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation

### Clinical Feature
- 80% are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of headache, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoencephalitis, and acute flaccid paralysis (especially in those >60 yr)

### Investigations
- IgM antibody in serum or CSF is the best test (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood, and fluids (all have low sensitivity)
- CSF: elevated lymphocytes and protein if CNS involvement

### Treatment and Prevention
- treatment: supportive
- prevention: mosquito repellant (DEET, picaridin), drain stagnant water, community mosquito control programs

# Syphilis

## Etiology
- *Treponema pallidum*: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

## Clinical Feature
- see Dermatology, D31 and Gynecology, GY29
- multi-stage disease
  1. primary syphilis (3-90 d post-infection)
     - painless chancre at inoculation site (any mucosal surface)
     - regional lymphadenopathy
     - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
  2. secondary syphilis = systemic infection (2-8 wk following chancre)
     - maculo-papular non-pruritic rash including palms and soles
     - generalized lymphadenopathy, low grade fever, malaise, headache, aseptic meningitis, ocular/otic syphilis
     - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
  3. latent syphilis
     - asymptomatic infection that follows untreated primary/secondary syphilis
     - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
     - increased transmission risk with early latent; longer treatment duration required for late latent
  4. tertiary syphilis (1-30 yr post-infection)
     - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
     - aortic aneurysm and aortic insufficiency
     - neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis
  5. congenital syphilis
     - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
     - most infected newborns are asymptomatic
     - clinical manifestations in early infancy include rhinitis (snuffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis), and rash (usually maculopapular and involving palms and soles)
     - late onset manifestations (>2 yr of age) include saddle nose, saber shins, Clutton joints, Hutchinson's teeth, mulberry molars, rhagades, CN VIII deafness, interstitial keratitis, juvenile paresis

## Investigations
- syphilis tests are conducted by public health labs. Thus order set for syphilis is simplified and does not require specification of which test to complete. Below are details on what tests are conducted at the public health lab
- screening tests: CMIA, CLIA, EIA (treponemal), RPR, or VDRL (non-treponemal)
- confirmatory tests: TPPA, FTA-ABS, MHA-TP, TPI
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others
- for congenital syphilis, LP is essential; long bone x-rays may also be helpful

## Treatment
- for 1°, 2°, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3°, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if truly allergic to penicillin: doxycycline 100 mg PO bid x 14 d is a second line therapy
- for pregnant patients allergic to penicillin, oral desensitization techniques are considered safe
- neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d ± single dose of benzathine penicillin
- for congenital syphilis, penicillin G IV x 10 d
- see Family Medicine, FM43 for generalized STI workup

**Argyll Robertson Pupil**
Accommodates but does not react to light

**Those with Untreated 1° or 2° Syphilis**
1/3 cure
1/3 latent indefinitely
1/3 3° syphilis

**Causes of False Positive VDRL and RPR Tests**

**V**iruses (mononucleosis, hepatitis)
**D**rugs and substance abuse
**R**heumatic fever
**L**upus and leprosy

Patients with 2° or 3° syphilis treated with penicillin may experience a Jarisch-Herxheimer reaction. Lysis of organisms release pyrogens thought to cause fever, chills, myalgia, flu-like symptoms may last up to 24 h

# Tuberculosis

**Tuberculous Polyserositis**
pleural + pericardial + peritoneal effusions (usually from granuloma breakdown that spills TB into pleural cavity – very rare)

## Etiology, Epidemiology, and Natural History

- 1/3 of the world's population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 90% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 1-2 yr of initial infection) at a pulmonary or extra-pulmonary site

## Risk Factors

- social and environmental factors
  - travel or birth in a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - Aboriginal (particular inuit), the incident of TB is 25 times higher in Canadian-born aboriginal compare to Canadian-born nonaboriginal
  - personal/occupational contact, crowded living conditions, low SES/homeless, IVDU
- host factors
  - immunocompromised/ (especially HIV, including extremes of age)
  - immunosuppressed (TNF**α** inhibitors, glucocorticoids)
  - silicosis
  - chronic kidney disease requiring dialysis
  - diabetes
  - malignancy and chemotherapy
  - substance use (e.g. drug use, alcoholism, smoking)

## Clinical Feature

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms

1. pulmonary TB
   - chronic productive cough ± hemoptysis, fever, night sweats, weight loss, chest pain, anorexia
   - CXR consolidation or cavitation, lymphadenopathy, predominantly upper lung findings but variable
   - non-resolving pneumonia despite standard antimicrobial therapy
2. miliary TB
   - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
   - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung
3. extra-pulmonary TB
   - can occur in any organ - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott's disease), adrenal (causing Addison disease), renal, ovarian

## Investigations

- screening for latent TB may be done via tuberculin skin test (TST) or IFN-γ release assay (IGRA)
  - both can be used to diagnose prior TB exposure. IGRA has fewer false positives as does not detect antigens in BCG vaccine or most types of non-tuberculosis-Mycobacteria
    - neither should be used for active TB diagnosis or monitoring anti-TB treatment response
    - TST preferred when repeat testing planned to assess risk of new infection (e.g. serial testing in healthcare)
  - IGRA preferred when BCG vaccine after 1 year of age, vaccination more than once, or unable to return for reading
- diagnostic tests/investigations for active pulmonary TB
  - sputum specimens (either spontaneous or induced) should be collected for acid-fast bacilli smear and culture; the three specimens can be collected on the same day, a minimum of 1 hour apart
  - BAL if other lung pathology (e.g. lung cancer) also suspected, or TB suspected despite negative sputum samples
  - CXR
    - classic triad: apical-posterior infiltrates, lung volume loss, cavitation
    - atypical features: hilar/mediastinal lymphadenopathy, non-cavitary infiltrates
    - signs of complications: endobronchial spread, pleural effusion, pneumothorax
    - ghon complex: a parenchymal granuloma, indicating a previous tuberculosis infection, and an involved hilar lymph node on the same side

### Prevention

- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against pediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection or immunodeficiency; widely used in other countries
- RIF (10 mg/kg [600 mg maximum]) daily for 4 mo
  - INH (5 mg/kg [300 mg maximum]) and RIF (10 mg/kg [600 mg maximum]) daily for 3 mo
  - INH (15 mg/kg [900 mg maximum]) and RPT (dose by weight) weekly for 3 mo
  - INH (5 mg/kg [300 mg maximum]) daily for 6 to 9 mo

### Treatment of Active Infection

- given the nuances of TB treatment, active TB infection should be managed by an experienced TB clinician
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol x 2 mo (initiation phase), then INH + rifampin x 4 mo in fully susceptible TB (continuation phase), total 6 mo. Extend continuation phase to 7 mo if >65, pregnant or risk of hepatotoxicity
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin ± others
  - XDR = resistance to INH + rifampin + fluoroquinolone + ≥1 of injectable, second-line agents
- very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
  - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information)

**Positive TST Test**
If induration at 48-72 h
>5 mm if immunocompromised, close contact with active TB
>10 mm all others; positive PPD CXR; decision to treat depends on individual risk factors
**False(–):** poor technique, anergy, immunosuppression, infection <10 wk or remotely
**False(+):** BCG after 12 mo of age in a low-risk individual, NTM
Booster effect: initially false(–) result boost to a true(+) result by the testing procedure itself (usually if patient was infected long ago so had diminished delayed type hypersensitivity reaction or if history of BCG)

**TB Treatment**

**RIPE**
**R**ifampin, **I**NH, **P**yrazinamide, **E**thambutol

# HIV and AIDS

## Epidemiology

### Canadian Situation (Public Health Agency of Canada, 2016)

- estimated 65,040 Canadians living with HIV infection at the end of 2016, 20% unaware of HIV-positive status
- 2090 new infections were reported in 2013: MSM account for 53% of cases, IDU 19%

### Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2018)

- estimated 36.7 million people living with HIV/AIDS at the end of 2016
- estimated 1.8 million newly infected in 2016
- estimated 1 million AIDS-related deaths in 2016

## Etiology

- HIV is a retrovirus that causes progressive immune system dysfunction, predisposing patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17) and capsid (p24), enclosing 2 single-stranded copies of RNA plus enzymes in its core
- virion glycoproteins bind CD4 and CCR5/CXCR4 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by viral reverse transcriptase; dsDNA is integrated into host genome by viral integrase
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover

# Modes of Transmission

**Table 18. Modes of Transmission in Adolescents and Adults by Site and Medium**

| HIV Invasion Site | Sub-Location | Transmission Medium | Transmission Probability per Exposure Event |
|---|---|---|---|
| Female genital tract | Vagina, ectocervix, endocervix | Semen | 1 in 200 to 1 in 2000 |
| Male genital tract | Inner foreskin, penile urethra | Cervicovaginal and rectal secretions and desquamations | 1 in 700 to 1 in 3000 |
| Intestinal tract | Rectum, upper GI tract | Semen<br>Semen<br>Maternal blood/genital secretions (intrapartum)<br>Breastmilk | 1 in 20 to 1 in 300<br>1 in 2500<br>1 in 5 to 1 in 10<br>1 in 5 to 1 in 10 |
| Placenta | Chorionic villi | Maternal blood (intrauterine) | 1 in 10 to 1 in 20 |
| Blood stream | | Contaminated blood products<br>Sharp/needlestick injuries | 95 in 100<br>1 in 150 |

Adapted with permission from Macmillan Publishers Ltd. Nat Rev Immunology 2008;8:447-457
NOTE: these estimates are for "all comers" i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)

p24 = capsid protein
gp41 = fusion and entry
gp120 = attachment to host T-cell

Homozygosity for A32 mutation in CCR5 gene confers relative resistance to HIV infection
Heterozygosity for A32 mutation in CCR5 gene associated with slower disease course

# Natural History

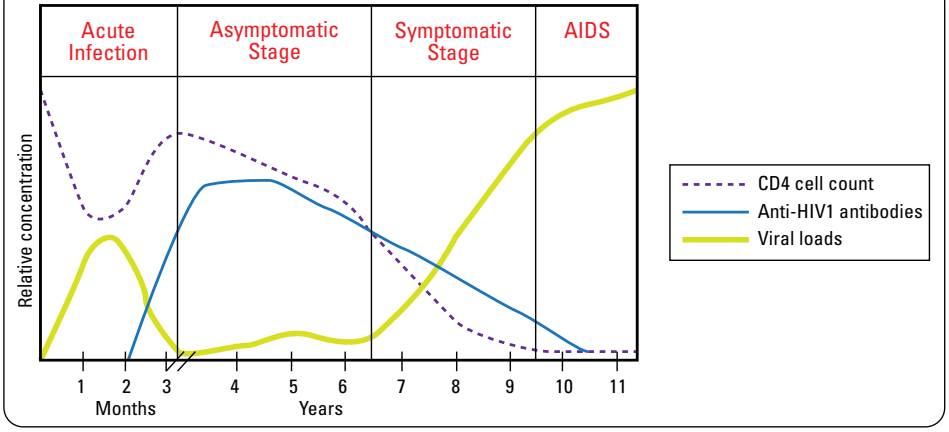

**Figure 7. Relationships between CD4 T-cell count, viral load, and anti-HIV antibodies**

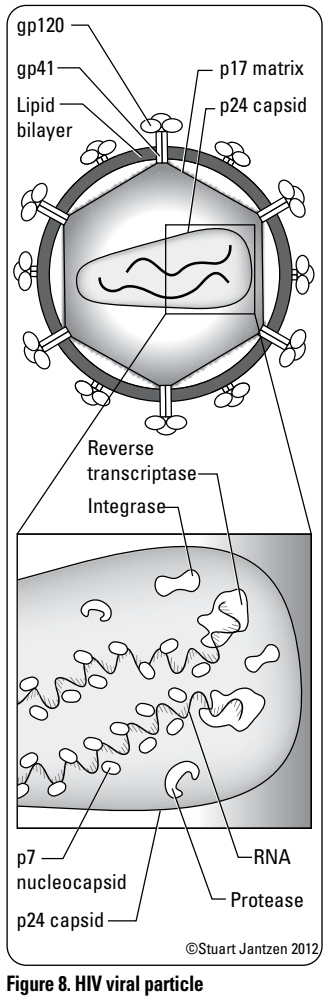

**Figure 8. HIV viral particle**

## Acute (Infection) Retroviral Syndrome

- 40-90% experience an acute "flu-like" illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, headache, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high risk of transmission

## Asymptomatic (Latent) Stage

- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count in adults: 500-1100 cells/mm$^3$
- CD4 count drops 60-100 cells/mm$^3$ per year but is variable
- by 10 yr post-infection, 50% have advanced HIV (i.e. AIDS), 30% demonstrate milder symptoms, and <20% are asymptomatic if untreated

## Definition of AIDS

- HIV-positive AND one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. *Pneumocystis jiroveci* pneumonia (PJP, previously PCP), esophageal candidiasis, CMV, MAC, TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome OR CD4 <200 (or <15%); this is largely historical since ART can reverse CD4 count decline

**Table 19. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)**

| CD4 Counts | Possible Manifestations |
|---|---|
| **<500 cells/mm³** | Often asymptomatic<br>Constitutional symptoms: fever, night sweats, fatigue, weight loss<br>Mucocutaneous lesions: seborrheic dermatitis, HSV, VZV (shingles), oral hairy leukoplakia (EBV), candidiasis (oral, esophageal, vaginal), Kaposi's sarcoma (KS)<br>Recurrent bacterial infections, especially pneumonia<br>Pulmonary and extrapulmonary tuberculosis<br>Lymphoma |
| **<200 cells/mm³** | *Pneumocystis jiroveci* pneumonia (formerly PCP)<br>KS<br>Oral thrush<br>Local and/or disseminated fungal infections: *Cryptococcus neoformans, Coccidioides immitis, Histoplasma capsulatum* |
| **<100 cells/mm³** | Progressive multifocal leukoencephalopathy (PML) – JC virus<br>CNS toxoplasmosis |
| **<50 cells/mm³** | CMV infection: retinitis, colitis, cholangiopathy, CNS disease<br>*Mycobacterium avium* complex (MAC)<br>*Bacillary angiomatosis* (disseminated *Bartonella*)<br>Primary central nervous system lymphoma (PCNSL) |

## Laboratory Diagnosis

- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): enzyme linked immunosorbent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
- increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%
- rapid (point of care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during "window period"

## Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
  - if non-stable and non-suppressed viral load, order routine CD4 count to measure status of the immune system
  - routine HIV-RNA levels (viral load) also important indicator of effect of ART
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B*5701 genetic test to screen for abacavir hypersensitivity if considering abacavir in treatment regimen
  - CCR5 tropism testing if considering CCR5 antagonist in treatment regimen
  - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasmosis, CMV, VZV)
  - routine biochemistry and hematology, CXR, urinalysis
  - annual fasting lipid profile and fasting glucose (due to ART side effects)
- education
  - regular follow-up on CD4 counts and viral loads (q3-6mo) (not necessary if suppressed viral load) as well as strict adherence to ART improves prognosis
  - prevention of further transmission through safer sex and clean needles for IDU
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) does rarely occur so barrier protection during sex is still recommended
  - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
  - connect to relevant community groups and resources
- health care maintenance
  - assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative), HPV
  - annual screening (PAP smear, STIs)
  - management of comorbid conditions and provision of general primary care

**Sexual Activity Without Condoms and Risk of HIV Transmission in Serodifferent Couples When the HIV-Positive Partner Is Using Suppressive Antiretroviral Therapy**
JAMA 2016;316(2):171-81
**Objective**: To evaluate the rate of within-couple HIV transmission (heterosexual and MSM) during periods of sex without condoms and when the HIV+ partner had HIV-1 RNA <200 copies/mL.
**Methods**: Prospective, observational PARTNER study, enrolled 1166 HIV serodifferent couples (in which the HIV+ partner was taking ART) reported having condomless sex. Primary outcome was risk of within-couple HIV transmission to HIV- partner.
**Results**: Enrolled couples provided 1238 eligible couple-years of follow-up. Couples reported condomless sex for a median of 2 yr and condomless sex with other partners was reported by 108 HIV- MSM and 21 heterosexuals. While 11 HIV- partners became HIV+ (10 MSM; 1 heterosexual), no phylogenetically linked transmissions occurred over eligible couple-years of follow-up (within-couple HIV transmission = 0, 95% CI 0.30-0.71 per 100 couple-years).
**Conclusions**: Among serodifferent heterosexual and MSM couples in which HIV+ partner was using ART and who reported condomless sex, during median 1.3 yr/couple follow-up, there were no documented cases of within-couple transmission.

**Seroconversion:** Development of detectable anti-HIV antibodies

**Window Period:** Time between infection and development of anti-HIV antibodies; when serologic tests (ELISA, Western blot) are negative

All infants born to HIV infected mothers have positive ELISA tests because of circulating maternal anti-HIV antibodies, which disappear by 18 mo; early diagnosis is made by detection of HIV RNA in plasma

**HLA-B*5701 Testing**
Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of Caucasians, lower prevalence in other ethnic groups). Routine screening for HLA-B*5701 at baseline and definitely prior to abacavir use

**HIV Status**
- CD4 count: progress and stage of disease
- Viral load: rate of progression

**Table 20. Prophylaxis Against Opportunistic Infections in HIV-infected Patients**

| Pathogen | Indication for Prophylaxis | Prophylactic Regimen |
|---|---|---|
| *Pneumocystis jiroveci* | CD4 count <200 cells/mm$^3$ or history of oral candidiasis | TMP-SMX 1 SS or DS OD |
| *Toxoplasma gondii* | IgG antibody to *Toxoplasma* and CD4 count <100 cells/mm$^3$ | TMP-SMX 1 DS OD |
| *Mycobacterium tuberculosis* | PPD reaction >5 mm or contact with case of active TB | INH + pyridoxine daily x 9 mo<br>Rifampin daily x4mo<br>Rifapentine + INH + pyridoxine daily x 12 wk |
| *Mycobacterium avium* complex | CD4 count <50 cells/mm$^3$ | No prophylaxis if patients are started ARTs |

SS = single strength; DS = double strength
See USPHS/IDSA guidelines for preventing opportunistic infections among HIV-infected persons (Relevant Sections updated 2013, 2015). Available from: http://aidsinfo.nih.gov/

# Anti-Retroviral Treatment

## Overall Treatment Principles

- recommended that all HIV+ patients initiate combination ART to restore and preserve immune function, reduce morbidity, prolong survival, and prevent transmission
- patients starting ART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case by case basis
- consider results of baseline resistance testing and complete ART history before (re-) initiating ART
- goal: keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunological function
- strong evidence against intermittent ART or 'drug holidays'
- patient with undetectable viral load adhering to ART does not transmit HIV to sexual partners

## ART Recommendations for Treatment of Naïve Patients

- 2 NRTIs + 1 INSTI/PI (boosted with ritonavir or cobicistat)
- **note**: guidelines are subject to frequent change. Combination therapy is suggested, preferably with single pill regimens

## Treatment Failure

- defined primarily by viral load (persistently >200 copies/mL)
- ensure that viral load >40 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, perform resistance testing

**Table 21. Anti-Retroviral Drugs**

| Class | Drugs | Mechanism | Adverse Effects |
|---|---|---|---|
| **Nucleoside reverse transcriptase inhibitors (NRTIs)** | abacavir (ABC)<br>emtricitabine (FTC)<br>lamivudine (3TC)<br>tenofovir disoproxil fumarate (TDF)<br>zidovudine (AZT)<br>**Combination Tablets:**<br>AZT/3TC (Combivir®)<br>AZT/3TC/ABC (Trizivir®)<br>ABC/3TC (Kivexa®)<br>TDF/FTC (Truvada®) | Incorporated into the growing viral DNA chain, thereby competitively inhibiting reverse transcriptase and terminating viral DNA growth | Lactic acidosis (often secondary to mitochondrial toxicity)<br>Lipodystrophy<br>Rash<br>Nausea/vomiting/diarrhea<br>Bone marrow suppression (AZT)<br>Peripheral neuropathy (ddI, d4T)<br>Drug-induced hypersensitivity (ABC)<br>Pancreatitis (ddI/d4T)<br>Myopathy (AZT) |
| **Non-nucleoside reverse transcriptase inhibitors (NNRTIs)** | delavirdine (DLV)<br>doravirine (DOR)<br>efavirenz (EFZ)<br>etravirine (ETR)<br>nevirapine (NVP)<br>rilpivirine (RPV) | Non-competitively inhibit function of reverse transcriptase, thereby preventing viral RNA replication | Rash, Stevens-Johnson syndrome<br>CNS: dizziness, insomnia, somnolence, abnormal dreams (efavirenz)<br>Hepatotoxicity (nevirapine – avoid in females with CD4 >250, men with CD4 >400)<br>CYP3A4 interactions |
| **Protease inhibitors (PIs)*** | atazanavir (ATV)<br>darunavir (DRV)<br>lopinavir/ritonavir (LPV/r)<br>nelfinavir (NFV)<br>ritonavir (RTV)<br>*tipranavir* (TPV) | Prevent maturation of infectious virions by inhibiting the cleavage of polyproteins | Lipodystrophy, metabolic syndrome<br>Nausea/vomiting/diarrhea<br>Nephrolithiasis (indinavir)<br>Rash (APV)<br>Hyperbilirubinemia (atazanavir, indinavir)<br>CYP3A4 interactions<br>Hyperlipidemia |
| **Integrase strand transfer inhibitors (INSTIs)** | bictegravir<br>dolutegravir (DTG)<br>elvitegravir (EVG)<br>raltegravir (RAL) | Inhibits integration of HIV DNA into the human genome thus preventing HIV replication | |
| **Fusion inhibitor (only used if resistance)** | enfuvirtide (T-20) | Inhibit viral fusion with T-cells by inhibiting gp41, preventing cell infection | Injection site reactions, rash, infection, diarrhea, nausea, fatigue |
| **CCR5 antagonist** | maraviroc (MVC) | Inhibit viral entry by blocking host CCR5 co-receptor | Fever, cough, dizziness |

*Standard of care is to pharmacologically boost most PIs with ritonavir to increase concentrations

1° and 2° prophylaxis may be discontinued if CD4 count is above threshold for ≥6 mo while on ART

**Anti-Retroviral pre-exposure prophylaxis (PrEP) for preventing HIV in high-risk individuals**
Cochrane DB Syst Rev 2012 Jul 11;7:CD007189
**Purpose**: To evaluate the efficacy of oral anti-retroviral prophylactic therapy in preventing HIV infection.
**Study**: Systematic review of 12 randomized controlled trials with 6 trials forming the core analysis.
**Population**: 9849 HIV-uninfected patients at high risk of contracting HIV including men who have sex with men, serodiscordant couples, and others.
**Outcome**: New infection with HIV.
**Results**: Daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) reduced the risk of HIV acquisition compared to placebo (RR 0.49; 95% CI 0.28-0.85). TDF alone also showed significant risk reduction in trials with fewer patients (RR 0.33; 95% CI 0.20-0.55). There was no significant increase in adverse events in any of the treatment groups. Sexual practices and adherence did not differ between treatment and placebo arms.
**Conclusions**: Pre-exposure prophylaxis with TDF with or without FTC effectively reduces the risk of HIV aquisition in high risk, HIV uninfected patients without causing significant adverse effects.

**Reasons for Deterioration of a Patient with HIV/AIDS**

- Opportunistic infections
- Neoplasms
- Medication-related toxicities
- Co-infections (e.g. HBV, HCV, STIs)
- Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)

**Treatment Failure**

- Assess adherence
- Assess drug interactions
- Resistance testing
- Rule out opportunistic infections
- Rule out marrow suppression
- Construct new 3-drug regimen

**Lactic Acidosis**

- Occurs secondary to mitochondrial toxicity
- Symptoms include abdominal pain, fatigue, nausea/vomiting, muscle weakness

**Lipodystrophy**
Body fat redistribution (mainly with old ARVs)

- Lipohypertrophy (e.g. dorsal fat pad, breast enlargement, increased abdominal girth) thought to be caused primarily by protease inhibitors
- Lipoatrophy (e.g. facial thinning, decreased adipose tissue in the extremities) is thought to be caused by thymidine analogue NRTIs such as d4T and AZT
- Metabolic abnormalities: lipids (increased LDL, increased TGs), glucose (insulin resistance, type 2 DM), increased risk of CVD

## Single Tablet ART Regimens

- reduces pill burden and increases adherence
- generally better tolerated

**Table 22. Single Tablet ART Regimens**

| Name | Contents | Common Side Effects |
|---|---|---|
| **Genvoya®** | tenofovir/emtricitabine/elvitegravir/cobicistat | good side effect profile |
| **Complera®** | rilpivirine/emtricitabine/tenofovir | good side effect profile |
| **Odefsey®** | rilpivirine/emtricitabine/tenofovir alafenamide | good side effect profile |
| **Stribild®** | elvitegravir/cobicistat/emtricitabine/tenofovir | good side effect profile |
| **Triumeq®** | dolutegravir/abacavir/lamivudine | good side effect profile; use only in HLAB*5701 negative patients |
| **Atripla®** | efavirenz/tenofovir/emtricitabine | psychiatric events, vivid dreams |

*Standard of care is to pharmacologically boost most PIs with ritonavir to increase concentrations

## Recommended ARV Regimens for Treatment-Naïve HIV-infected Adults

- initial regimens for treatment (all include an integrase inhibitor and a pair of NRTIs):
  1. Bictegravir/TAF/FTC
  2. Dolutegravir/ABC/3TC
  3. Dolutegravir + TAF (or TDF)/FTC
  4. Elvitegravir/cobicistat/TAF (or TDF)/FTC
  5. Raltegravir + TAF (or TDF)/FTC

  Note: Not all regimens available in all regions.

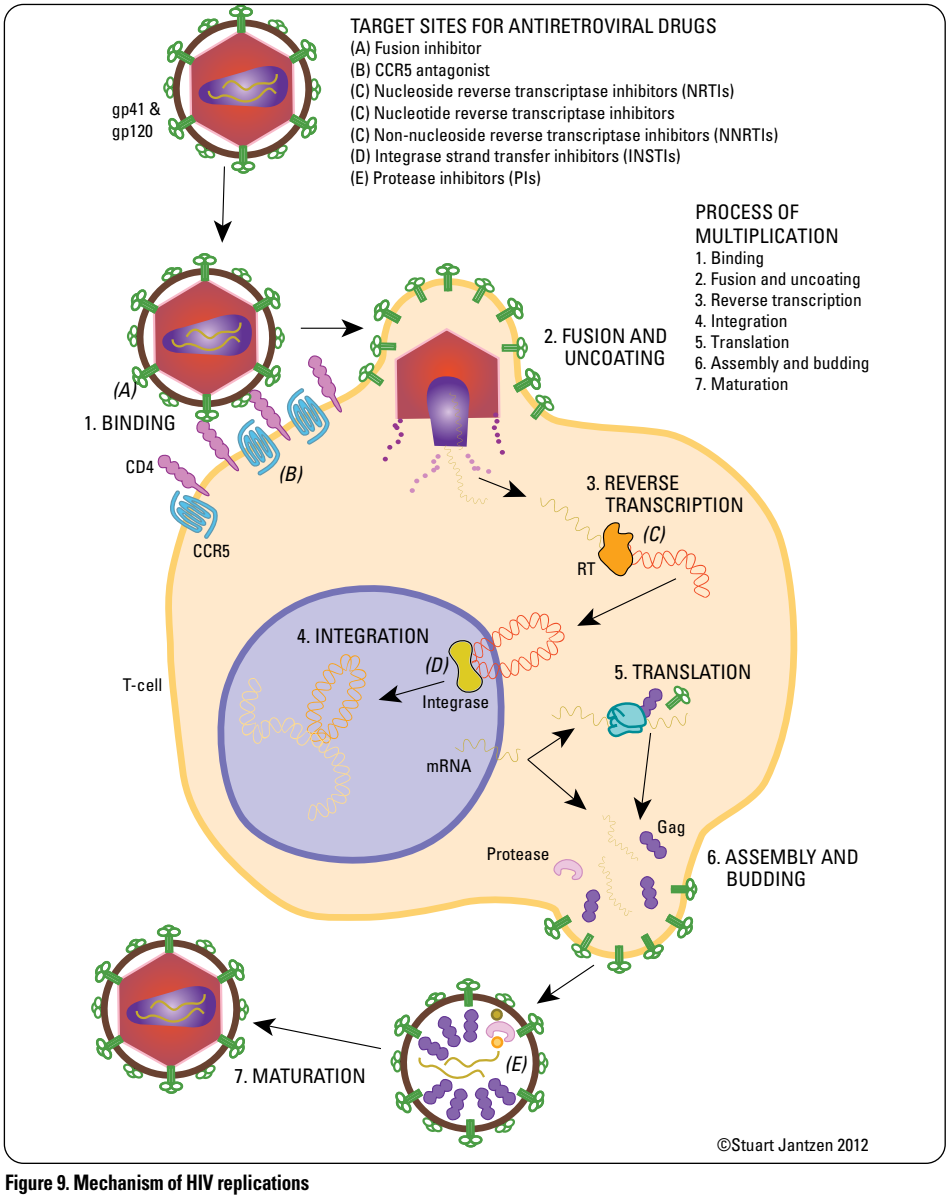

**Figure 9. Mechanism of HIV replications**

# Prevention of HIV Infection

- education, including harm-reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for IVDU: avoid sharing needles
- prevention of vertical HIV infection: treatment with ART should be initiated prior to pregnancy or as early as possible during pregnancy. The risk of vertical HIV transmission can be reduced to <1% if maternal ART is started in a timely manner and the maternal viral load is undetectable prior to delivery
- universal blood and body precautions for health care workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation

# Types of Testing

**1. Nominal/Name-Based HIV Testing**
- person ordering the test knows the identity of the person being tested for HIV
- HIV test is ordered using the name of the person being tested
- person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
- test result is recorded in the health care record of the person being tested

**2. Non-Nominal/Non-Identifying HIV Testing**
- similar to nominal/name-based testing on all points except:
  - HIV test is ordered using a code or the initials of the person being tested

**3. Anonymous Testing**
- available at specialized clinics
- person ordering the HIV test does not know the identity of the person being tested
- HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
- test results are not recorded on the health care record of the person being tested
- patient identification and notification of Public Health required to gain access to ART

# HIV Pre- and Post-Test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

Early identification of HIV is essential for patients to receive the maximal benefit from ART

**Efficacy, Safety, and Effect on Sexual Behaviour of On-Demand Pre-Exposure Prophylaxis for HIV in Men Who Have Sex With Men: An Observational Cohort Study**
Lancet HIV 2017;4(9):e402-10.
**Objective**: Assess the efficacy, safety, and effect of on-demand pre-exposure prophylaxis (PrEP) on sexual behaviour.
**Methods**: Men and transgender women who have sex with men, previously enrolled in the placebo-controlled ANRS IPERGAU trial. On demand tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg) to be taken before and after sexual intercourse and participants assessed for incidence of HIV, PrEP adherence, safety, and sexual behaviour.
**Results**: HIV incidence was 0.19/100 person-years (95% CI 0.01-1.08) vs. 6.60/100 person-years (95% CI 3.60-11.05) in the placebo group, relative risk reduction of 97%. Drug-related GI events were reported in 14% of participants, but were self-limiting. Participants reporting condomless sex at their last receptive anal intercourse increased from 77 to 86% at 18 mo follow-up.
**Conclusions**: On-demand oral PrEP is highly effective at preventing HIV infection among high-risk men who have sex with men. This represents an alternative to daily PrEP.

**Use of a Vaginal Ring Containing Dapivirine for HIV-1 Prevention in Women**
NEJM 2016;375:2121-32.
**Objectives**: To evaluate whether longer-acting methods of anti-retroviral therapy (i.e. vaginal rings) may simplify use of medications and provide HIV-1 protection.
**Methods**: Phase 3, randomized, double-blind, placebo-controlled trial of monthly vaginal ring containing dapivirine in women (aged 18-45) in Malawi, South Africa, Uganda, and Zimbabwe.
**Results**: Among 2629 women enrolled, the incidence of HIV-1 infection was 3.3/100 person-years in dapivirine group and 4.5/100-years in placebo group. Post hoc analysis identified higher rates of HIV-1 protection in women >21 yr (56%, 95% CI 31-71) but not among those 21 yr (-27%, 95% CI -133-31), which correlated with reduced adherence.
**Conclusions**: Monthly vaginal ring containing dapivirine reduced risk of HIV-1 infection among African women.

# Fungal Infections

## Skin and Subcutaneous Infections

## Superficial Fungal Infections

- see Dermatology, D5

## Dermatophytes

- see Dermatology, D26

# Subcutaneous Fungal Infection

### Etiology
- subcutaneous inoculation by fungi that naturally reside in the soil, including *Sporothrix schenckii*, which usually occurs in gardeners injured by a rose thorn or splinter

### Clinical Feature
- causes subcutaneous nodules at the point of entry, may develop into an ulcer
- fungi may migrate up lymphatic vessels creating nodules along the way – "nodular lymphangitis"

### Treatment
- oral azole
- IV amphotericin B for severe or disseminated infection

# Endemic Mycoses

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts, and bat caves

### Etiology
- fungal infection that occurs through the inhalation of spores (from soil, bird droppings, vegetation) or inoculation injury
- thermally dimorphic organisms: mould in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
- in North America, the three major endemic mycoses are: histoplasmosis, blastomycosis, and coccidioidmycosis

### Clinical Feature
- may be asymptomatic
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromised states

### Treatment
- almost never empiric, and requires diagnosis first
- common to all endemic mycoses
  - oral azole (e.g. itraconazole for mild-moderate local infection)
  - IV amphotericin B for systemic infection

**Table 23. Endemic Mycoses**

| Disease | Endemic Region | Clinical Features | Investigations |
|---|---|---|---|
| ***Histoplasma capsulatum*** | Ohio and Mississippi River valleys in central USA, Ontario, Quebec; widespread | Asymptomatic (in most people)<br>Primary pulmonary<br>• Fever, cough, chest pain, headache, myalgia, anorexia<br>• CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy<br>• CXR (chronic): pulmonary infiltrates, cavitary disease<br>Disseminated (rare)<br>• Occurs primarily in immunocompromised patients<br>• Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS | Fungal culture, fungal stain<br>Antigen detection (urine and serum)<br>Serology |
| ***Blastomyces dermatitidis*** | States east of Mississippi River, Northern Ontario and along the Great Lakes | May be asymptomatic<br>Primary: acute or chronic pneumonia<br>• Fever, cough, chest pain, chills, night sweats, weight loss<br>• CXR (acute): lobar or segmental pneumonia<br>• CXR (chronic): lobar infiltrates, fibronodular interstitial disease<br>Disseminated<br>• Spread to skin (verrucous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), GU tract (prostatitis, epididymitis) | Sputum smear and culture<br>Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material) |
| ***Coccidioides immitis*** | Deserts in southwest USA, northwest Mexico | Primary<br>• "Valley fever": subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for wk to mo<br>• Can develop hypersensitivity with arthralgias, erythema nodosum<br>Disseminated<br>• Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis)<br>• Common opportunistic infection in patients with HIV | Sputum culture<br>Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material) |

# Opportunistic Fungi

## *Pneumocystis jiroveci* (formerly *P. carinii*) Pneumonia: PJP or PCP

### Etiology
- respiratory exposure to unicellular fungi (previously classified as a protozoa)
- rarely transmitted from person to person
- without prophylaxis, HIV-positive patients with a CD4 count <200 cells/mm3 have an 80% lifetime risk of PJP

### Clinical Feature
- symptoms of pneumonia: fever, non-productive cough, progressive dyspnea (and hypoxia)
- classic CXR findings of interstitial pneumonia
- most clinical disease is due to reactivation of latent infection or reinfection by a different genotype in immunocompromised patients (steroid use, HIV)

**CXR in *P. jiroveci***
- Bilateral, diffuse opacities
- CXR may be normal (20-30% cases)
- CT shows cysts (hence the name Pneumo"cystis") but almost never pleural effusions

### Investigations
- serum LDH elevated in nearly all cases
- visualization (immunofluorescence) or detection (PCR) of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)

### Treatment and Prevention
- oxygen to keep $SaO_2$ >90%
- antimicrobial options
  - TMP/SMX (PO or IV) is preferred therapy
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV) is second line in severe disease
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia ($pO_2$ <70 mmHg or A-a gradient $O_2$ >35 mmHg)
- prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 <200 cells/$mm^3$ or non-HIV immunocompromised patients under specific conditions)

## *Cryptococcus* spp.

### Etiology
- inhalation of airborne encapsulated yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gatti*)
- *C. neoformans* tends to affect immunocompromised hosts vs. *C. gatti* which tends to affect immunocompetent hosts

*C. gattii* sees limited geographical distribution including Vancouver Island, Northern Australia, and Papua New Guinea

### Clinical Feature
- asymptomatic
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*
  - other: bone, lymph nodes, bone marrow, soft tissues, eyes, prostate

### Investigations
- serum cryptococcal antigen
- CSF for meningitis: India-ink stain or cryptococcal antigen test, culture to confirm
- lateral flow cryptococcal antigen assay from serum and cerebrospinal fluid
- lumbar puncture with measurement of opening pressure

India-ink sensitivity for *Cryptococcus* is only 50% (higher in HIV patients); now replaced by cryptococcal antigen test in most laboratories

### Treatment
- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

# *Candida albicans*

### Etiology
- overgrowth of *C. albicans* (normally found as part of the microbiome of the skin, mouth, vagina, and GI tract)
- risk factors for overgrowth:
  - immunocompromised state (DM, corticosteroids)
  - critically ill patients (broad-spectrum antibiotic use, central venous catheters, TPN)
  - obesity → maceration and moisture in intertriginous areas, pannus, under breasts

### Clinical Feature
- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see Gynecology, GY26), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

### Treatment
- thrush: nystatin suspension or pastilles for mild disease, fluconazole for severe disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

# *Aspergillus* spp.

### Etiology
- infection with *Aspergillus* fungi (*A. fumi, A. flavus*) which is found ubiquitously in the air and the environment
- *Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains, and rice

### Clinical Feature
- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a pre-existing lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes ("air crescent" sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia or transplantation
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass ("halo" sign)
- mycotoxicosis
  - aflatoxin produced by *A. flavus* (nuts, grains, rice)
  - results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

### Treatment Options
- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for Allergic Bronchopulmonary Aspergillosis

# Parasitic Infections

## Protozoa – Intestinal/Genitourinary Infections

### *Entamoeba histolytica* (Amoebiasis)

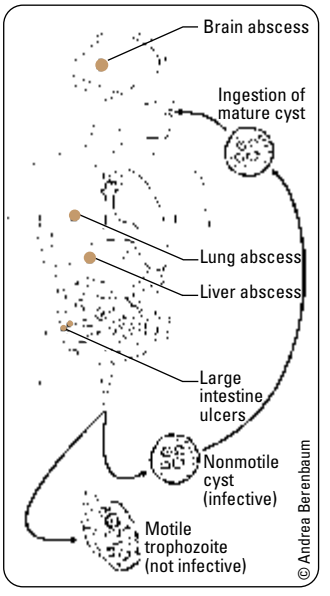

**Figure 10. *Entamoeba* life cycle**

#### Etiology
- infection with *E. histolytica* occurs when the cysts are transmitted via the oral-fecal route in areas of poor sanitation that have been contaminated by other infected humans
- seen in migrants, travellers, institutionalized individuals, Indigenous peoples, MSM

#### Clinical Feature
1. asymptomatic carriers
2. amoebic dysentery
   - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction, and ulceration of large intestine
3. amoebic abscesses (liver abscesses, see General Surgery, GS48)
   - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
   - can also occur in lungs and brain

#### Investigations
- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- *E. histolytica* indistinguishable microscopically from the non-pathogen *E. dispar* (distinguish by specific stool antigen detection)

#### Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

### *Giardia lamblia*

#### Etiology
- infection with *G. lamblia* occurs via the fecal-oral route with the ingestion of cysts from water/food contaminated by infected humans and other mammals (especially in the Rockies)
- risk factors: travel, camping, institutions, daycare centres, MSM

#### Clinical Feature
- giardiasis ("beaver fever")
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucous in stool

#### Investigations
- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

#### Treatment and Prevention
- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

### *Trichomonas vaginalis*

#### Etiology
- infection with *T. vaginalis* occurs via sexual contact

#### Clinical Feature
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- *Trichomonas* vaginitis (see Gynecology, GY26)
- vaginal discharge (profuse, malodourous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

### Investigations
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

### Treatment
- metronidazole for patient and partner(s)

*Trichomonas* causes 25% of vaginitis

## *Cryptosporidium* spp.

### Etiology
- infection with *Cryptosporidium* spp. via the fecal-oral route occurs with the ingestion of cysts from water contaminated by infected humans and other animals (including cows)
- risk factors: summer and fall, young children (daycare), MSM, contact with farm animals, immunodeficiency

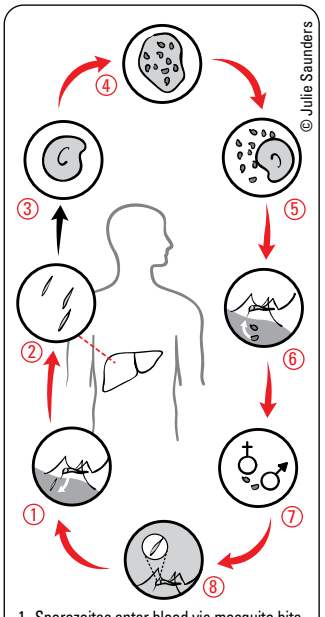
### Clinical Feature
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with nausea/vomiting, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

### Investigations
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

### Treatment and Prevention
- supportive care
- in HIV+ patients, (re)initiate ART and try to increase their CD4 count to >100; if fails, try nitazoxanide or macrolides
- good personal hygiene, water filtration

**Mefloquine for Preventing Malaria During Travel to Endemic Areas**
Cochrane DB Syst Rev 2017;CD006491.
**Objectives:** To summarize efficacy and safety of mefloquine used as prophylaxis for malaria in travellers.
**Methods:** RCTs (for efficacy and safety) and non-randomized cohort studies (for safety) to compare prophylactic mefloquine with placebo, no treatment, or alternative antimalarial agent.
**Results:** Participants were more likely to discontinue mefloquine (6%) vs. atovaquone-proguanil (3%) due to adverse effects (including nausea, vomiting, abnormal dreams, insomnia, anxiety, and depressed mood during travel). No difference in serious adverse effects or discontinuation due to adverse effects was found between mefloquine and doxycycline or mefloquine and chloroquine.
**Conclusions:** Absolute risk of malaria during short-term travel appears low with mefloquine, doxycycline, and atovaquone-proguanil therapy. Choice of agent depends on how individual travellers assess importance of specific adverse effects, pill burden, and cost.

# Blood and Tissue Infections



## *Plasmodium* spp. (Malaria)

### Etiology
- transmission of *Plasmodium* spp. (*P. falciparum, P. vivax, P. ovale, P. malariae, P. knowlesi*) primarily occurs during the blood meal of a night biting female Anopheles mosquito
- sporozoites injected during the blood meal then infect human liver cells, where they multiply and are released as merozoites; merozoites infect RBCs and cause disease
- infection with malaria parasites can also occur via vertical transmission (rare) or blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

### Clinical Feature
- flu-like prodrome (may include fever, chills, fatigue, diaphoresis, cough, rash, arthralgias, myalgias, headache, GI symptoms)
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs) (lasts several hours)
  - *P. vivax* and *P. ovale*: chills and fever x48 h but can be variable
  - *P. malariae*: chills and fever x72 h but can be variable
  - P. *falciparum*: less predictable fever interval, can be highly variable
- abdominal pain, diarrhea, myalgia, headache, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis
- >90% of patients infected with *P. falciparum* are ill within 30 d
- relapsing malarial attacks may occur after many months due to the reactivation (entering the erythrocytic cycle) of dormant liver hypnozoites of either *P. ovale* or *P. vivax*
- complications:
  - *P. falciparum* (most common and most lethal): CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
  - *P. knowlesi*, and rarely *P. vivax*, can be fatal

### Investigations
- CBC screen (assess for triad of: thrombocytopenia, elevated LDH, and atypical lymphocytes)
- microscopy: blood smear q12-24h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests

Malaria is the most common fatal infectious disease worldwide

1. Sporozoites enter blood via mosquito bite, infect liver
2. Hepatic infiltration
3. Infect red blood cells
4. Trophozoite divides asexually many times to produce schizont (contains merozoites)
5. Red blood cell lyses and merozoites attack other red blood cells (chills and fever)
6. Male and female gametocytes (from merozoites) ingested by mosquito during bite
7. Male and female gametocytes (from merozoites) fuse in mosquito gut; produce ookinete
8. Ookinete matures into an oocyst which contains individual sporozoites; migrates to mosquito salivary glands

**Figure 11. Life cycle of *Plasmodium* spp.**

### Treatment and Prevention
- *P. vivax, P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- *P. vivax*, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- *P. malariae, P. knowlesi*: chloroquine
- *P. falciparum*: most areas of the world show chloroquine resistance – check local resistance patterns
  - artemisinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - atovaquone/proguanil combination (Malarone®)
  - quinine + doxycycline or clindamycin
  - mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- prevention with antimalarial prophylaxis (although quality may vary regionally), covering exposed skin, bed nets, insect repellent
- prevention of relapse for *P. vivax*: tafenoquine (in patients aged 16 years and older who are receiving appropriate antimalarial therapy for acute *P. vivax* infection)

**Drugs for Preventing Malaria in Travellers**
Cochrane DB Syst Rev 2009;CD006491
**Study**: Cochrane Systematic Review. 8 RCTs.
**Population**: 4240 non-immune adults and children traveling to regions with *P. falciparum* resistance to chloroquine.
**Intervention**: Atovaquone-proguanil, doxycycline, mefloquine, chloroquine-proguanil, or primaquine used for malaria prophylaxsis.
**Outcome**: Efficacy, safety, and tolerability.
**Results**: Atovaquone-proguanil and doxycycline had similar adverse events. Atovaquone-proguanil had fewer overall (RR 0.72), GI (RR 0.54), and neuropsychiatric events (RR 0.49) than mefloquine. Doxycycline also had fewer neuropsychiatric events than mefloquine (RR 0.84).
**Conclusion**: Atovaquone-proguanil or doxycycline as prophylaxis against malaria is best tolerated in terms of adverse effects and mefloquine is associated with adverse neuropsychiatric outcomes.

## *Trypanosoma cruzi*

### Etiology
- found in Mexico, South America, and Central America
- transmission by Reduviid insect vector ("Kissing Bug"), which defecates on skin and trypomastigotes in the stool are rubbed into bite site by host
- also transmitted via placental transfer, organ donation, blood transfusion, and ingestion of contaminated food containing Reduviid insects (especially cane juice)

### Clinical Feature
- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation ("Romana's sign"; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood; most infected persons (60-70%) remain in this phase, and do not go on to manifest a determinate form of Chagas disease
  - chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

### Investigations
- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

### Treatment and Prevention
- acute: nifurtimox or benznidazole
- indeterminate: increasing trend to treat as acute infection for children and adults under age 50 years
- chronic determinate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there may be a benefit to antiparasitic treatment
- insect control, bed nets

**Classic Triad of Congenital Toxoplasmosis**
- Chorioretinitis
- Hydrocephalus
- Intracranial calcifications

## *Toxoplasma gondii*

### Etiology
- infection with *T. gondii* occurs through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions, contaminated water sources

### Clinical Feature
- congenital
  - result of acute primary infection of mother during pregnancy (TORCH infection)
  - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
  - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 <200)
  - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (headache and focal neurological signs)
  - lymph node, liver, spleen enlargement, and pneumonitis
  - chorioretinitis

### Investigations
- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination

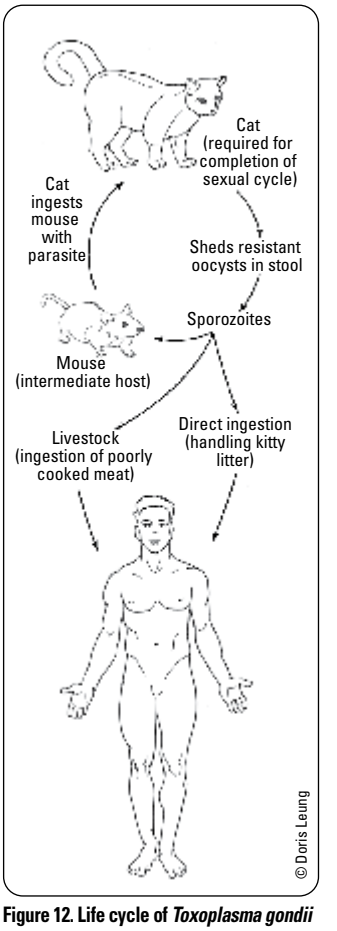


**Figure 12. Life cycle of *Toxoplasma gondii***

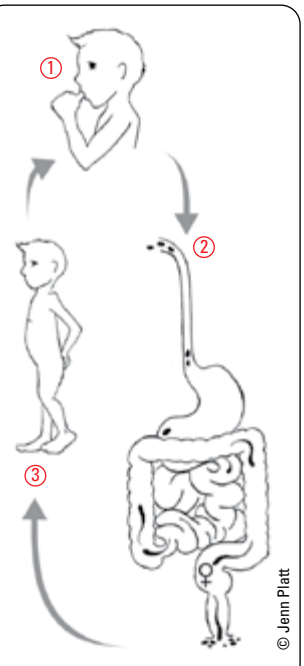
### Treatment and Prevention

- no treatment if: immunocompetent, not pregnant, no severe organ damage
- pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folinic acid), avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: TMP/SMX
- proper hand hygiene, cook meat thoroughly to proper temperature



1/3 of Ontario's population is infected with *Toxoplasma gondii*

# Helminths

## Roundworms – Nematodes

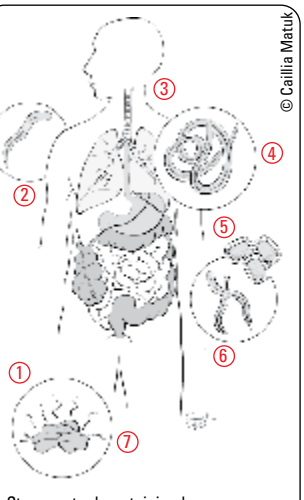


**Table 24. Nematodes (Roundworms)**

| Nematode | Epidemiology | Transmission | Medical Importance | Treatment |
|---|---|---|---|---|
| *Ascaris lumbricoides* | Tropics | Human feces, ingestion of contaminated food or water containing eggs | Abdominal pain and intestinal obstruction from high worm burden<br>Cough, dyspnea, pulmonary infiltrates from larval migration through lungs (Löffler's syndrome) | Mebendazole OR albendazole OR pyrantel pamoate |
| *Trichuris trichiura* (whipworm) | Tropics | Ingestion of eggs in soil | Diarrhea (± mucous, blood), abdominal pain, rectal prolapse, stunted growth | Mebendazole OR albendazole |
| *Onchocerca volvulus* | Africa, Latin America | Blackfly bite | River blindness (onchocerciasis), dermatitis | Ivermectin + doxycycline |
| *Wuchereria bancrofti* | Tropics | Mosquito bite | Damage to lymphatics resulting in lymphadenopathy, lymphedema, and elephantiasis Tropical pulmonary eosinophilia | Diethylcarbamazine + doxycycline |
| *Loa Loa* | Central Africa | Deer fly bite | Subcutaneous migration of worm, hyperresponsiveness in travellers | Diethylcarbamazine |
| *Enterobius vermicularis* (Pinworm) | Worldwide | Human host: fecal-oral self-inoculation and fomite person-to-person transfer<br>Adult worms live in cecum and deposit eggs in peri-anal skin | Asymptomatic carriers or severe nocturnal peri-anal itching (pruritus ani) Occasional vaginitis, ectopic migration to appendix or other pelvic organs Abdominal pain, nausea/vomiting with high worm burden | Sticky tape test: eggs adhere to tape applied to perianal skin (need 5-7 tests to rule out)<br>Examination of perianal skin at night may reveal adult worms<br>Usually no eosinophilia as no tissue invasion<br>Mebendazole, albendazole; pyrantel in pregnancy<br>Change underwear, bathe in morning, pajamas to bed, wash hands, trim fingernails<br>Treat all family members simultaneously<br>Reinfection common |
| *Strongyloides stercoralis* (Threadworm) | Subtropical, tropical, and temperate (including southern US) | Fecal contamination of soil: transmission via unbroken skin, walking barefoot<br>Autoinfection: penetration of larvae through GI mucosa or perianal skin<br>Adult worms live in mucosa of small intestine | One of few worms able to multiply in human host<br>Mostly asymptomatic infection or can have pruritic dermatitis at site of larval penetration<br>Transient pulmonary symptoms during pulmonary migration of larvae (eosinophilic pneumonitis = Löffler's syndrome)<br>Abdominal pain, diarrhea, pruritis ani, larva currens (itchy rash)<br>Hyperinfection: occasional fatal cases caused by massive auto-infection in immunocompromised host; immunoablative therapy, including high-dose corticosteroids, is the most common risk factor for disseminated infection | Ivermectin (OR Albendazole) |

1. Embryonated eggs ingested by humans
2. Larvae hatch in small intestine
3. Females migrate out anus at night

**Figure 13. Life cycle of *Enterobius***

1. Step on stool containing larvae
2. Larvae migrate to lungs via bloodstream
3. Larvae crawl up trachea and down to GI tract (cough/swallow)
4. Adult worms in intestine
5. Eggs produced in bowel
6. Larvae
7. Bowel movement containing larvae

**Figure 14. Life cycle of *Strongyloides***

# Flatworms

## Cestodes/Trematodes

**Table 25. Cestodes/Trematodes (Flatworms)**

| | Epidemiology | Transmission | Medical Importance | Treatment |
|---|---|---|---|---|
| **CESTODES** | | | | |
| *Taenia solium* | Developing countries | Undercooked pork (larvae), human feces (eggs) | Taeniasis: mild abdominal symptoms<br>Cysticercosis: mass lesions in CNS, eyes, skin, seizures | Corticosteroids + albendazole for cysticercosis<br>Antiepileptics if seizures<br>Praziquantel for adult tapeworm in gut (taeniasis) |
| *Taenia saginata* | Developing countries | Undercooked beef (larvae) | Mild GI symptoms | Praziquantel |
| *Diphyllobothrium latum* | Europe, North America, Asia | Raw fish | B12 deficiency leading to macrocytic anemia and posterior column deficits | Praziquantel |
| *Echinococcus granulosus* | Rural areas, Sheep-raising countries | Dog feces (eggs) | Liver/lung cysts (enlarge between 1-20 yr; may cause mass effect or rupture)<br>Risk of anaphylaxis if cystic fluid released during surgical evacuation | Albendazole ± praziquantel alone<br>Surgery + perioperative albendazole<br>Percutaneous aspiration + perioperative albendazole |
| **TREMATODES** | | | | |
| *Clonorchis sinensis* | Japan, Taiwan, China, SE Asia | Raw fish | Exists in bile ducts, causes inflammation and sometimes cholangiocarcinoma | Praziquantel |
| *Schistosoma* spp. | Africa, SE Asia, focal in Western Hemisphere | Fresh water exposure | Chronic sequelae secondary to long-term infection (e.g. chronic liver disease, SCC of the bladder) | Praziquantel |

## *Schistosoma* spp.

### Etiology

- infection with *Schistosoma* spp. (*S. mansoni, S. hematobium, S. japonicum*) occurs following penetration of unbroken skin by their larvae (cercariae) which are found in infested fresh water
- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- eggs must reach fresh water to hatch where they infect an intermediate host (snails) which then release cercariae into the water
- schistosomes cannot multiply in or pass between humans
- more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

### Clinical Feature

- most asymptomatic; symptoms seen in travellers (nonimmune)
- swimmer's itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, headache, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia
- chronic schistosomiasis (can persist for years):
  - *S. mansoni, S. japonicum*
    - worms in mesenteric vein, eggs in portal tracts of liver and bowel
    - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2° to portal HTN), hepatomegaly
  - *S. hematobium*
    - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
    - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
  - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
  - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

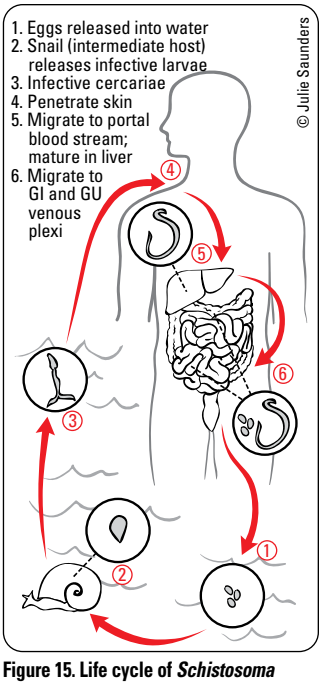

**Figure 15. Life cycle of *Schistosoma***

### Investigations

- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia), loop-mediated isothermal amplification
- *S. mansoni, S. japonicum*: eggs in stool, liver U/S shows fibrosis, rectal biopsy
- *S. hematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

### Treatment and Prevention
- praziquantel
- add glucocorticoid if acute schistosomiasis or neurologic complications develop
- proper disposal of human fecal waste, molluscicide (pesticide against molluscs), avoidance of infested fresh water while traveling

## Ectoparasites
- scabies, lice
- see Dermatology, D27

# Travel Medicine

## General Travel Precautions
- vector-borne: long sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings, and bed nets, and skin repellents (such as DEET) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller's diarrhea (bismuth salicylate)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

### Infectious Diseases to Consider
- vector borne: malaria, dengue fever, Chikungunya, yellow fever, spotted fever rickettsioses, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, leishmaniasis, Zika virus
- sexually transmitted: HIV, HBV, acute HSV, syphilis, usual STIs
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis
- airborne: TB
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller's diarrhea, cholera, *Campylobacter* spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

## Fever in the Returned Traveller

### Etiology
- commonly identified causes of fever in returning traveller
  - parasitic: malaria (20-30%)
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from *Salmonella* (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller's diarrhea (10-20%), RTI (10-15%), UTI/STI (2-3%)
- febrile illness in travellers can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes (e.g. DVT, PE)

### History
- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
- persons visiting friends and family more likely to be exposed to local population and pathogens
  - style of travel: lodgings, camping, adventure travelling
  - local population: sick contacts
  - transportation: use of animals

For up to date information on geographic and seasonal patterns of disease and travel advisories, check the website for the United States Centres for Disease Control and Prevention (wwwnc.cdc.gov/travel) or Foreign Affairs Canada (travel.gc.ca)

**Important Exposures**

| | |
|---|---|
| **Insect Bites** | |
| Mosquito | • *Plasmodium* spp. (Malaria)<br>• Dengue<br>• *Chikunguny*<br>• Lymphatic filariasis (Elephantiasis)<br>• West Nile Encephalitis<br>• Yellow Fever<br>• Japanese Encephalitis |
| Tick | • *Borrelia burgdorferi* (Lyme Disease)<br>• *Rickettsia rickettsii* (Rocky Mountain Spotted Fever) |
| Fly | • *Trypanosoma brucei* spp. (African sleeping sickness)<br>• *Leishmania* spp. (Leishmaniasis)<br>• *Bartonella bacilliformis* (Bartonellosis) |
| Flea | • *Yersinia* (Plague)<br>• *Tunga penetrans* (Tungiasis) |
| **Mammal Bites** | |
| Dog/Cat | • Rabies, *Pasteurella*, anaerobes, *Streptococcus, S. aureus* |
| Human | • *Streptococcus, S. aureus*, oral anaerobes, *Eikenella* |
| **Oral Exposures** | |
| Unpasteurized Milk | • *Brucella* spp., non-tuberculous *Mycobacteria, Salmonella, E. coli, Listeria* |
| Undercooked Meat/Fish | • Enteric bacteria, helminths, protozoa |
| Water | • Hepatitis A/E, Norwalk, cholera, *Salmonella, Shigella, Giardia,* poliovirus, *Cryptosporidium, Cyclospora* |
| **Environmental Exposures** | |
| Fresh Water | • *Leptospira* spp., schistosomes, *Acanthamoeba, Naegleria fowleri* |
| Soil | • Hookworms, *Toxocara* spp. (visceral larva migrans), *Leptospira interrogans* (leptospirosis) |

Adapted with permission from *Lancet* 2003;361:1459-69

- exposure history
  - street foods, untreated water: increased risk of traveller's diarrhea, enteric fever
  - uncooked meat/unpasteurized dairy: increased risk of parasitic infection
  - body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  - increased risk of HBV, HCV, HIV, GC, *C. trachomatis*, syphilis
  - animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
- fever pattern
- incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  - <21 d: consider malaria, typhoid fever, dengue fever, chikunguny, rickettsioses; exclude HBV, TB
  - >21 d: consider malaria, TB, typhoid fever; exclude dengue fever, chikungunya, traveller's diarrhea, rickettsioses
- body systems affected: GI, respiratory, CNS, skin

## Investigations

- all travellers with fever should undergo the following tests
  - blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  - urine: urinalysis, urine C&S if dysuria or other localizing signs
- special tests based on symptoms, exposure history, and geography
  - stool: C&S, O&P
  - CXR
  - dengue serology for IgM

Fever in traveller from malaria endemic area is malaria until proven otherwise

**Pregnancy and Zika Virus**
For women and men who have been diagnosed with Zika virus or who have symptoms of Zika including fever, rash, joint pain or red eyes after possible exposure to Zika virus, CDC recommends:
- Women wait at least 8 wk after their symptoms first appeared before trying to get pregnant
- Men wait at least 6 mo after their symptoms first appeared to have unprotected sex
- For men and women without symptoms of Zika virus but who had possible exposure to Zika from recent travel or sexual contact, CDC recommends healthcare providers advise their patients wait at least 8 wk after their possible exposure before trying to get pregnant in order to minimize risk

**Table 26. Fever in the Returned Traveller**

| Illness | Geography/Timing | Pathogen | Incubation Period | Clinical Manifestations | Diagnosis | Treatment |
|---|---|---|---|---|---|---|
| **Malaria** | Africa<br>India<br>C. and S. America<br>SE Asia<br>Usually rural, night-biting mosquitoes | *Plasmodium falciparum*<br>*Plasmodium vivax*<br>*P. malaraie*<br>*P. ovale*<br>*P. knowlesi* | 7-30 d to mo or yr | Fever and flu-like illness, (shaking chills, headache, muscle aches, and fatigue)<br>Nausea/vomiting and diarrhea<br>Anemia and jaundice Plasmodium falciparum: (severe) kidney failure, seizures, mental confusion, prostration, coma, death, respiratory failure | Blood smear (thick and thin) x3<br>Rapid Diagnostic Test (with smear or PCR confirmation)<br>Antigen detection PCR (mostly a research tool) | Artesunate (for severe disease) + malarone, doxycycline, or clindamycin<br>Quinine sulfate + doxycycline or clindamycin<br>Chloroquine + primaquine |
| **Dengue** | South East Asia<br>Caribbean<br>Usually urban, day-biting mosquitoes | Dengue viruses | 3 d to 2 wk | Sudden onset of fever, headache, retro-orbital pain, myalgias, and arthralgias<br>Leukopenia<br>Thrombocytopenia Hemorrhagic manifestations (rare in travellers) | Anti-dengue IgM positivity | Symptom relief: Acetaminophen (avoid using NSAIDs because of anticoagulant properties) |
| **Typhoid (enteric fever)** | Global but mostly Indian subcontinent | *Salmonella typhi*<br>*Salmonella paratyphi* | 3 to 60 d | Sustained fever 39°-40°C (103°-104°F)<br>Abdominal pain, headache, loss of appetite, cough, constipation | Stool, urine, or blood sample positive for *S. typhi* or *S. paratyphi* | Quinolone antibiotic (e.g. ciprofloxacin), ceftriaxone, or macrolide |
| **Tick Typhus** | Mediterranean<br>South Africa<br>India | *Rickettsia* | 1 to 2 wk | Fever, headache, fatigue, muscle aches, occasionally rash<br>Eschar at site of tick bite<br>Thrombocytopenia<br>Elevated liver enzymes | Serology<br>Presence of classic tick eschar | Doxycycline |
| **TB** | Global | *M. tuberculosis* | Variable | Fever, cough, hemoptysis | CXR<br>Sputum culture and acid-fast stain | Isoniazid (INH), rifamin (RIF), pyrazinamide (PZA), ethambutamol (EMB) + Vitamin B6 |
| **Mononucleosis** | Caribbean, C. and S. America | EBV or CMV | 30 to 50 d | Malaise, fatigue, pharyngitis, lymphadenopathy, splenomegaly | Atypical lymphocytes on blood smear and positive heterophilic antibody (monospot) test | Acetaminophen or NSAIDs, fluids |
| **Zika Virus Disease** | Africa, SE Asia, S. America; spreading | Zika virus | Unknown, likely 3 to 12 d | Headache, malaise, muscle/joint pain, mild fever, rash, conjunctivitis | RT-PCR<br>Serology | Rest, fluids, analgesics/antipyretics (avoid NSAIDs until Dengue ruled out), condom use, avoid pregnancy |

# Fever of Unknown Origin

**Table 27. Classification of Fever of Unknown Origin (FUO) – Temp >38.3°C/101°F on several occasions**

| Classical FUO | Nosocomial FUO | Neutropenic FUO | HIV-associated FUO |
|---|---|---|---|
| Duration >3 wk | Hospitalized patient<br>Infection not present/ incubating on admission | Neutrophil count <500/mL or is expected to fall to that level in 1-2 d | HIV infections<br>Duration >4 wk for outpatients, >3 d for hospitalized patients |
| Diagnosis uncertain after 3 outpatient visits or 3 d in hospital or 1 wk of intensive ambulatory investigation | Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures | Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures | Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures |

**Causes of Nosocomial FUO**
**B, C, D, E**
**B**acterial and fungal infections of respiratory tract and surgical sites
**C**atheters (intravascular and urinary)
**D**rugs
**E**mboli

## Etiology of Classic FUO

- infectious causes (~30%)
  - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - uncommon: viral (CMV, EBV), bacterial (brucellosis, bartonellosis), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin's) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - solid tumours: RCC (most common), also breast, liver (hepatoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still's disease
- miscellaneous (~20%)
  - drugs, factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown in 30-50% despite detailed workup

**Drugs that may Cause Fever**
- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimalarials)
- Anti-hypertensives (hydralazine, methyldopa)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arrythmics (quinine, procainamide)
- Anti-inflammatories (NSAIDs)
- Anti-thrombotics (ASA)
- Anti-histamines
- Anti-thyroid

## Approach to Classic FUO

- careful and repeated history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - blood work: CBC and differential, electrolytes, urea, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
  - cultures: blood (x2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
  - serology: HIV, monospot, CMV IgM
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent

# Infections in the Immunocompromised Host

## Factors that Compromise the Immune System

- general: age (very young or elderly), malnutrition
- immune disease: HIV, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

**Table 28. Types of Immunodeficiency**

| Type | Conditions | Vulnerable To |
|---|---|---|
| **Cell-Mediated Immunity** | HIV, Hodgkin, hairy cell leukemia, cytotoxic drugs, SCID, DiGeorge syndrome | Latent viruses<br>Fungi<br>Parasites<br>Nontuberculosis mycobacterium (NTM) |
| **Humoral Immunity** | CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome | Encapsulated organisms (*S. pneumoniae, H. influenzae, N. meningitidis, Salmonella typhi*, GBS) |
| **Neutrophil Function** | Chemotherapy, myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease | Catalase-producing organisms (*Staphylococcus, Serratia, Nocardia, Aspergillus*) |

**Infections Associated with Asplenia**

- *Haemophilus influenzae* type b
- *Streptococcus pneumoniae*
- *Neisseria* meningitidis
- *Salmonella*
- Babesiosis
- Malaria
- Capnocytophaga canimorsus (dog bite)

# Febrile Neutropenia

## Definition

- fever (≥38.3°C/101°F or ≥38.0°C/100.4°F for ≥1 h) and one of:
  - ANC <0.5 OR
  - ANC <1.0 but trending down to 0.5

ANC (absolute neutrophil count) = WBC x (%neutrophils + %bands)

## Pathophysiology

- decreased neutrophil production
  - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B12, folate
- increased peripheral neutrophil destruction
  - autoimmune: Felty's syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

Usual signs and symptoms of infection may be diminished because neutrophils are required for a robust inflammatory response; exam and x-ray findings may be more subtle

## Epidemiology/Etiology

- most common life-threatening complication of cancer therapy
- 8 cases per 1000 cancer patients per yr in the U.S.
- causative organism identified only 1/3 of the time
- GN (especially Pseudomonas) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially *Candida, Aspergillus*)
- Frequently associated with IV lines, mucosal or GI infection. *Typhlitis* (inflammation of cecum) is a rare complication, but can lead to serious infection and poor outcomes

WBC is lowest between 5-10 d after last chemotherapy cycle

## Investigations

- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region for perianal abscess
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and nasopharyngeal swab for respiratory viruses
- CBC and differential, Cr, urea, electrolytes, AST/ALT, total bilirubin, CXR (depending on stage of disease)

## Treatment

- most hospitals have their own specific protocol so check local guidelines first; one example see Figure 16

Prophylaxis against FN with G-CSF (granulocyte colony-stimulating factor) and GM-CSF (granulocyte-macrophage colony-stimulating factor) decreases hospitalization without affecting mortality (indicated if risk of FN 20% or if FN has occurred in a previous chemotherapy cycle)

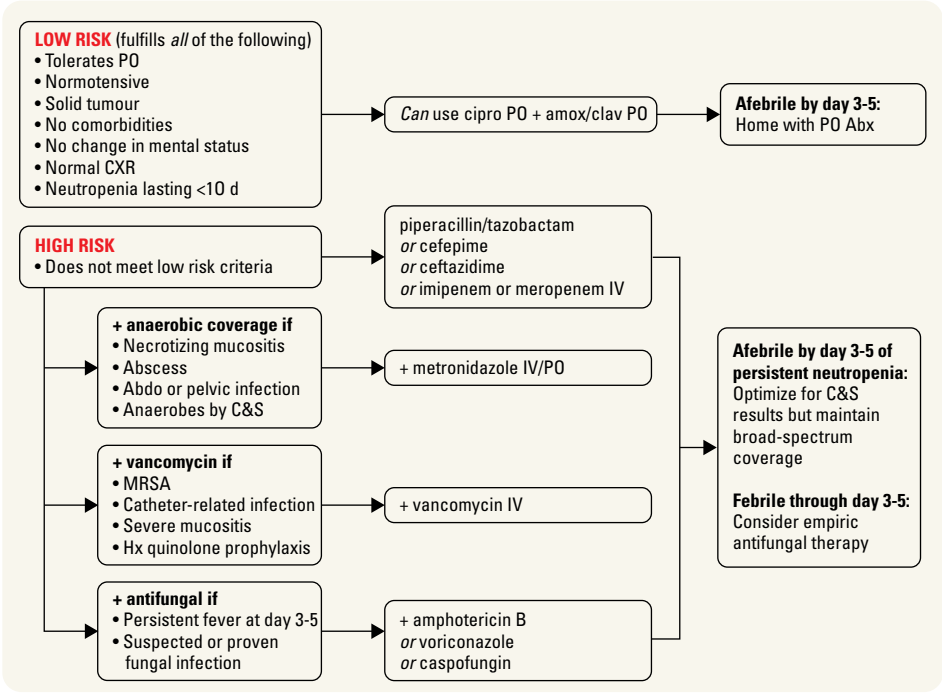

**Figure 16. Example of treatment protocol for febrile neutropenia**

# Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
  - viral (especially CMV, EBV, VZV)
  - fungal (especially *Aspergillus, Cryptococcus, P. jiroveci*)
  - protozoan (especially *Toxoplasma*)
  - unusual bacterial/mycobacterial infections (especially TB, *Nocardia, Listeria*)

### Prophylactic Vaccinations Given Before Transplant

- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B vaccines
- if low titre or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

# Immune Reconstitution Syndrome

### Definition

- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

### Etiology

- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in patients with advanced HIV or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- can occur in response to multiple infections
  - *Mycobacteria* (tuberculosis, avium complex)
  - *Cryptococcus*
  - *Pneumocystis*
  - *Toxoplasma*
  - HBV and HCV
  - herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - *Molluscum contagiosum*
- clinical features are dependent on the type and location of the pre-existing infection
- thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
- non-HIV conditions with documented IRS: solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy

### Epidemiology
- in HIV-positive patients starting ART, IRS reported to affect ~10%

### Investigations
- IRS is a diagnosis of exclusion
- rule out drug reaction, medication non-adherence, drug resistance

### Treatment
- continue ARV therapy in HIV-positive patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to ARV initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

# A Simplified Look at Antibiotics

- general overview, see Table 29, ID46 for more details

**1. Penicillins**

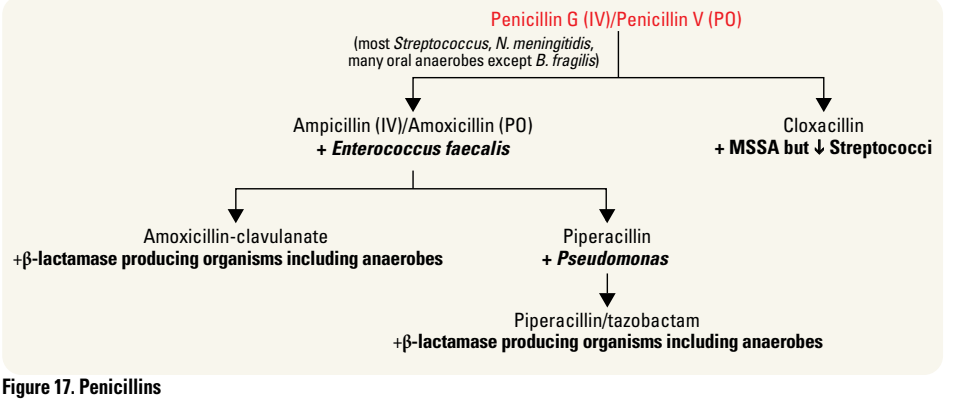

**Figure 17. Penicillins**

**2. Cephalosporins (PO/IV)**
- 1st generation: cephalexin/cefazolin (mostly GP, some GN) or cefadroxil
- 2nd generation: cefuroxime/cefprozil (some GP and some GN, *anaerobes)
- 3rd generation: cefixime/cefotaxime, ceftriaxone (good Streptococcal coverage, mostly GN), and ceftazidime (no GP, mostly GN, *Pseudomonas*)
- 4th generation: --/cefepime (most GP, *most* GN, *Pseudomonas*), ceftaroline (for MRSA)

**3. Aminoglycosides (GN aerobic bacilli include *Pseudomonas*)**
- gentamicin
- tobramycin
- amikacin
- plazomicin

**4. Macrolides (GP, *Haemophilus*, and atypical bacteria [*Legionella, Chlamydophila, Mycoplasma*])**
- erythromycin
- clarithromycin
- azithromycin

**5. Fluoroquinolones (GN – although resistance becoming a huge problem)**
- ciprofloxacin (+ *Pseudomonas*)
- norfloxacin (for spontaneous bacterial peritonitis (SBP) prophylaxis )
- "respiratory" fluoroquinolones (some GP, GN, "atypicals", *Legionella, Mycoplasma, Chlamydophila, Mycobacteria*)
  - levofloxacin
  - moxifloxacin (has some anaerobic coverage)

**6. Carbapenems (broad coverage: GP, GN, and anaerobes)**
- imipenem (+ *Pseudomonas*)
- meropenem (+ *Pseudomonas*)
- ertapenem

**7. Others**
- doxycycline/tetracycline/minocycline (GP, syphilis, *Chlamydophila, Rickettsia, Mycoplasma*)
- tigecycline (for resistant GP infections, GN, anaerobes, *Chlamydophila, Rickettsia, Mycoplasma*)
- vancomycin (all GP and *C. difficile* – the oral form for)
- linezolid (for resistant GP infections)
- daptomycin (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most *S. aureus* including: MRSA, GN aerobes, *Pneumocystis*)
- nitrofurantoin (GN bacilli, *S. saprophyticus, Enterococcus*)
- metronidazole (anaerobes including: *Bacteroides* sp., *C. difficile; Trichomonas, Entamoeba*)

# Antimicrobials

## Antibiotics

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S and clinical response
- if causative organism identified, use antibiotic to which organism is susceptible
- if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

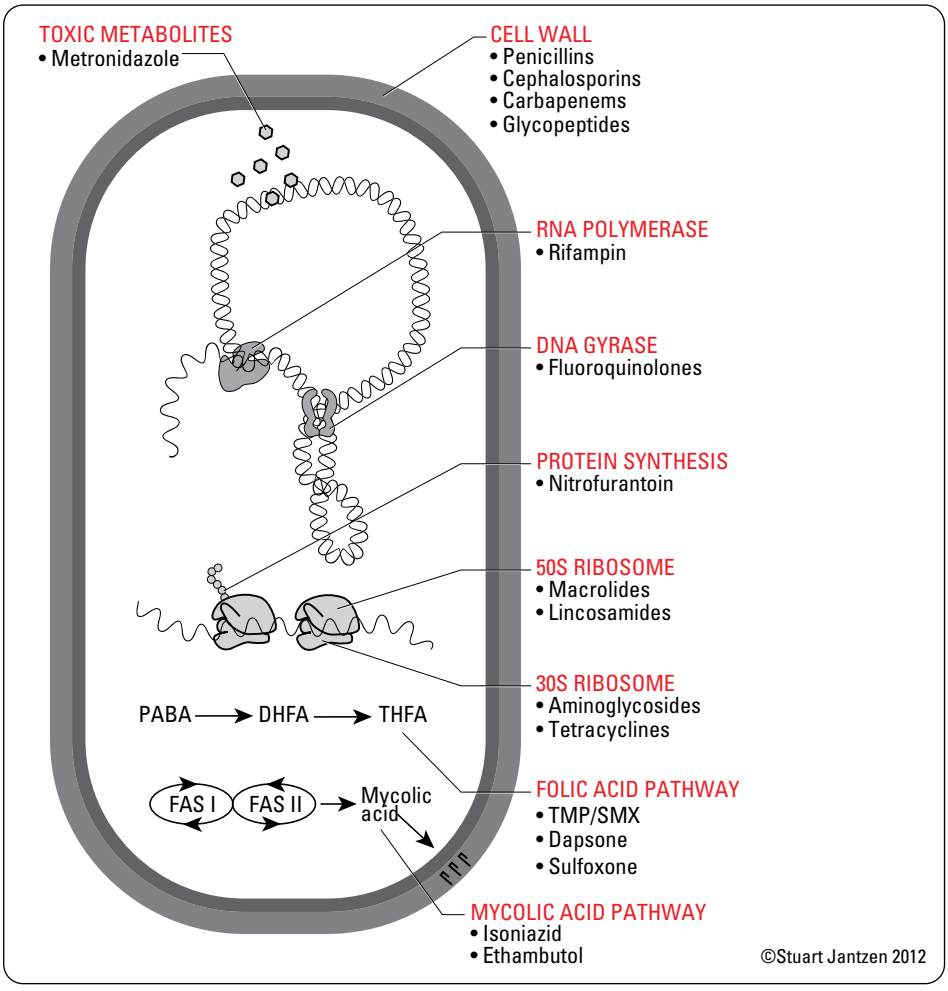

**Figure 18. Mechanism of action of antibiotics**

**Reasons for Combination Therapy**
- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. *Enterococcus* spp. causing endocarditis)
- To prevent emergence of resistance

| Bactericidal Antibiotics | Bacteriostatic Antibiotics |
|---|---|
| "**V**ery **F**inely **P**roficient **A**t **CC**ell **M**ur**D**er" | "**ECST**a**T**i**C**" |
| **V**ancomycin | **E**rythromycin (and other macrolides) |
| **F**luoroquinolones | **C**lindamycin |
| **P**enicillin | **S**ulfamethoxazole |
| **A**minoglycosides | **T**rimethoprim |
| **C**ephalosporins | **T**etracyclines |
| **C**arbapenems | **C**hloramphenicol |
| **M**etronidazole | |
| **D**aptomycin | |

## Table 29. Antibiotics

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Indications | Contraindications |
|---|---|---|---|---|---|
| **CELL WALL INHIBITORS** | | | | | |
| **Penicillins** | | | | | |
| Benzyl penicillin<br>- penicillin G IV/IM<br>- penicillin V PO | GP except *Staphylococcus, Enterococcus, N. meningitidis*,<br>Oral anaerobes<br>Syphilis | Bactericidal: β-lactam inhibits cell wall synthesis by binding penicillin binding protein (PBP) preventing cross-linking of peptidoglycan | Immediate allergy (IgE): anaphylaxis, urticaria<br>Late-onset allergy (IgG): urticaria, rash, serum sickness<br>Interstitial nephritis<br>Dose related toxicity: seizures<br>Diarrhea | Mild to moderately severe infections caused by susceptible organisms including: actinomycosis, streptococcal pharyngitis, streptococcal skin and soft tissue infections, pneumococcal pneumonia, syphilis | Hypersensitivity to penicillin cov? |
| Aminopenicillin<br>- ampicillin IV<br>- amoxicillin PO (Amoxil®) | Same as penicillin AND<br>*Enterococcus*<br>*Listeria*<br>Some strains of:<br>*H. influenzae,*<br>*E. coli,*<br>*K. pneumoniae* | See above | See above | Bacterial meningitis and endocarditis (IV ampicillin), acute otitis media (AOM), streptococcal pharyngitis, sinusitis, acute exacerbations of COPD, part of multidrug therapy for *H. pylori* treatment, Lyme disease, pneumococcal pneumonia; UTI (amoxicillin and ampicillin) for most enterococci and susceptible Gram negative pathogens | Hypersensitivity to penicillin or β-lactam antibiotics |
| Isoxazyolyl penicillin<br>- cloxacillin<br>- methicillin<br>- nafcillin<br>- oxacillin | Methicillin-sensitive *Staphylococcus aureus*; streptococci | See above | See above | Bacterial infections caused by staphylococci and streptococci including skin and soft-tissue infections | Hypersensitivity to cloxacillin or any penicillin |
| β-lactam/β-lactamase inhibitor combinations<br>- amoxicillin-clavulanate (Clavulin®, Augmentin®)<br>- piperacillin/tazobactam (Tazocin®) | Same as penicillin AND<br>*Staphylococcus*<br>*H. influenzae*<br>*Enterococcus*<br>Anaerobes (oral and gut) | β-lactamase produced by certain bacteria inactivate β-lactams Lactamase inhibitors prevent this process, preserving antibacterial effect of β-lactams | See above | Various β-lactamase producing bacteria, Clavulin® sensitive bacteria including RTI, sinusitis, AOM, skin and soft tissue infections, UTI, and severe intra-abdominal and pelvic infections | Hypersensitivity to penicillin or cephalosporin<br>History of Clavulin®-associated jaundice or hepatic dysfunction |
| **Cephalosporins** | | | | | |
| **PO**<br>1°<br>cephalexin (Keflex®) | **IV**<br>cefazolin (Ancef®) | **GP**<br>Good with the exception of *Enterococcus* and MRSA | **GN**<br>*E. coli, Klebsiella, Proteus, H. influenzae* (not all isolates) | Bactericidal: β-lactam inhibits PBP, prevents cross-linking of peptidoglycan, less susceptible to penicillinases | 10% penicillin allergy cross-reactivity | Skin and soft tissue infections, prevention of surgical site infections (cefazolin); infections caused by susceptible organisms (especially *Staph* and *Strep* infections) | Hypersensitivity to cephalosporins or other β-lactam antibiotics |
| 2°<br>cefuroxime (Ceftin®)<br>cefprozil (Cefzil®) | cefuroxime (Zinacef®)<br>cefoxitin[A] | Weaker activity than 1° | More coverage than 1° ([A]includes anaerobes) | See above | See above | Upper and lower respiratory tract infections; pneumococcal pneumonia; soft tissue infections | See above |
| 3° cefixime (Suprax®) | ceftriaxone (Rocephin®)<br>cefotaxime (Claforan®)<br>ceftazidime[B] (Fortaz®) | *S. aureus* + streptococcal coverage (cefotaxime and ceftriaxone) especially *S. pneumoniae* | Broad coverage ([B]includes *Pseudomonas* for ceftazidime only) | See above | ~1% penicillin allergy cross-reactivity | Community-acquired pneumonia (cefotaxime, ceftriaxone), gonorrhea (use ceftriaxone), community-acquired bacterial meningitis (ceftriaxone, cefotaxime); abdominal and pelvic infections (cefotaxime or ceftriaxone in combination with metronidazole); once-daily administration makes ceftriaxone convenient for outpatient IV therapy | Severe hypersensitivity (Type I) to other β-lactam antibiotics |
| 4° | cefepime (Maxipine®) | Broad spectrum | Broad coverage including *Pseudomonas* | See above | See above | Empiric therapy for febrile neutropenia | See above |

**Table 29. Antibiotics** (continued)

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Indications | Contraindications |
|---|---|---|---|---|---|
| **CELL WALL INHIBITORS** | | | | | |
| **Carbapenems** | | | | | |
| imipenem (Primaxin®) | GP except MRSA GN including *Pseudomonas* + *Enterobacter*, ESBLs, anaerobes | β-lactam inhibits PBP and prevents cross-linking of peptidoglycan | Penicillin allergy cross-reactivity<br>Seizures | Treatment of infections caused by GNB producing extended-spectrum β-lactamases, serious infections caused by susceptible organisms | Hypersensitivity to imipenem<br>Lowers seizure threshold compared to carbapenems |
| meropenem (Merrem®) | See above; does not cover *Enterococcus* | See above | See above | See above | Hypersensitivity to β-lactams |
| ertapenem (Invanz®) | GP except *Enterococcus*, MRSA GN including *Enterobacter* (but not *Pseudomonas*), anaerobes | See above | See above | See above; once-daily administration makes it convenient for outpatient IV therapy | Hypersensitivity to β-lactams |
| **Glycopeptides** | | | | | |
| Vancomycin (Vancocin®) | GP including MRSA, not VRE<br>*C. difficile* if PO | Glycopeptide sterically inhibits cell wall synthesis | Red Man Syndrome<br>Nephrotoxicity<br>Ototoxicity<br>Thrombocytopenia | Severe or life-threatening GP infections, patients with β-lactam allergy<br>May only be taken orally for severe *C. difficile* infection | Hypersensitivity to vancomycin |
| **PROTEIN SYNTHESIS INHIBITORS (50S RIBOSOME)** | | | | | |
| **Macrolides** | | | | | |
| erythromycin (Erybid®, Eryc®)<br>*This agent is rarely used due to GI upset | GP except *Enterococcus*<br>GN: *Legionella, B. pertussis*<br>"Atypicals": *Chlamydophila, Mycoplasma* | Binds to 50S ribosomal subunit inhibiting protein synthesis | GI upset<br>Acute cholestatic hepatitis<br>Prolonged QT | Susceptible RTI, pertussis, diphtheria, Legionnaires' disease, skin and soft tissue infections | Hypersensitivity to erythromycin<br>Concurrent therapy with astemizole, terfenadine |
| clarithromycin (Biaxin®) | See above, some mycobacteria | See above | See above | Susceptible RTI, skin infections, non-tuberculous mycobacterial infections, part of multidrug therapy for *H. pylori* treatment | Hypersensitivity to macrolides |
| azithromycin (Zithromax®) | See above, some mycobacteria | See above | See above | Susceptible RTI, acute exacerbations of COPD, community-acquired pneumonia, skin infections, *Campylobacter* infections if treatment indicated, chlamydia | Hypersensitivity to macrolides |
| **Lincosamides** | | | | | |
| clindamycin (Dalacin®) | GP except *Enterococcus*, most community-acquired MRSA<br>Anaerobes | Inhibits peptide bond formation at 50S ribosome | Pseudomembranous colitis and *C. difficile*<br>GI upset | Treatment of suspected or proven infections caused by GP, anaerobes including skin and skin structure infections, oropharyngeal infections, in combination with GN coverage for intra-abdominal and pelvic infections | Hypersensitivity to clindamycin<br>Infants <30 d |
| chloramphenicol | GP GN Anaerobes | Inhibits peptidyl transferase action of tRNA at 50S ribosome | Aplastic anemia<br>Grey Baby Syndrome | Serious infections by susceptible organisms when suitable alternatives are not available including meningococcal disease in patients with anaphylaxis to β-lactams | Hypersensitivity to chloramphenicol |
| linezolid (Zyvoxam®) | GP including VRE + MRSA | Binds 50S ribosome and prevents functional 70S initiation complex | HTN (acts as MAOI)<br>Risks with prolonged use: myelosuppression, optic neuropathy, peripheral neuropathy | Vancomycin-resistant *Enterococcus faecium* infections including intra-abdominal, skin and skin structure, and urinary tract infections, MRSA infections as outpatient therapy | Hypersensitivity to linezolid |

**Table 29. Antibiotics** (continued)

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Indications | Contraindications |
|---|---|---|---|---|---|
| **PROTEIN SYNTHESIS INHIBITORS (30S RIBOSOME)** | | | | | |
| **Aminoglycosides** | | | | | |
| gentamicin<br>tobramycin<br>amikacin (Amikin®) | GN (includes *Pseudomonas*) | Binds 30S subunit of ribosome inhibiting protein synthesis | Nephrotoxicity (reversible)<br>Vestibular and ototoxicity (irreversible)<br>Vestibular toxicity is the most important aminoglycoside toxicity | GN infections when alternatives do not exist, UTIs, used in low doses for synergy with β-lactams or with vancomycin for the treatment of serious enterococcal infections | Pre-existing hearing loss and renal dysfunction |
| **Tetracyclines** | | | | | |
| tetracycline (Apo-Tetra®, Nu-TetraT®)<br>minocycline (MinocinT®)<br>doxycycline (Doxycin®)<br>tigecycline (Tygacil®) | GP<br>Anaerobes<br>"Atypicals": *Chlamydophila, Mycoplasma, Rickettsia, Borrelia burgdorferi*<br>*Treponema*<br>Malaria prophylaxis (doxycycline)<br>Tigecycline has activity against MRSA, VRE, and ESBL-producing *E. coli/K. pneumoniae* | Binds 30S subunit of ribosome inhibiting protein synthesis | GI upset<br>Hepatotoxicity<br>Fanconi's syndrome<br>Photosensitivity<br>Teratogenic<br>Yellow teeth and stunted bone growth in children | Rickettsial infections, *Chlamydophila*, acne (tetracycline, minocycline), PID (step-down), malaria prophylaxis (doxycycline) | Severe renal or hepatic dysfunction<br>Pregnancy or lactation<br>Children under 8 yr |
| **TOPOISOMERASE INHIBITORS** | | | | | |
| **Fluoroquinolones (FQs)** | | | | | |
| ciprofloxacin (Cipro®)<br>norfloxacin (Apo-Norflox®)<br>ofloxacin (Floxin®)<br>Respiratory FQs:<br>levofloxacin (Levaquin®)<br>moxifloxacin (Avelox®) | Variable GP activity<br>GN (includes *Pseudomonas*)<br>Atypicals<br>Levofloxacin and Moxifloxacin cover *S. pneumoniae*<br>Moxifloxacin also has additional anaerobic coverage | Inhibits DNA gyrase | Headache, dizziness<br>Allergy<br>Seizures<br>Prolonged QT<br>Dysglycemia (levofloxacin, moxifloxacin)<br>Tendonitis<br>Tendon rupture | Upper and lower RTI (not ciprofloxacin unless susceptible organism isolated), UTI, prostatitis (not moxifloxacin), bone and joint infections for susceptible organisms, skin and soft tissue infections (levofloxacin, moxifloxacin), infectious diarrhea, meningococcal prophylaxis, intra-abdominal infections (moxifloxacin, ciprofloxacin in combination with metronidazole or clindamycin), febrile neutropenia prophylaxis (ciprofloxacin, levofloxacin) or ciprofloxacin in combination with amoxicillin-clavulanate low management of "low-risk" febrile neutropenia | |
| **OTHER** | | | | | |
| **Rifampin** | GP cocci<br>*N. meningitidis*<br>*H. influenzae*<br>*Mycobacteria* | Inhibits RNA polymerase | Hepatic dysfunction, P450 enzyme induction<br>Orange tears/saliva/urine | Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment of other mycobacterial infections, endocarditis involving prosthetic valve or other prosthetic device infections in combination with other antibiotic agents, prophylaxis for those exposed to people with *N. meningitidis* or HiB meningitis | Jaundice<br>Not to be used as monotherapy (except for prophylaxis) |
| **Metronidazole** (Flagyl®) | Anaerobes Protozoa | Forms toxic metabolites in bacterial cell which damage microbial DNA | Disulfiram-type reaction with EtOH<br>Seizures<br>Peripheral neuropathy | Protozoal infections (trichomoniasis, amoebiasis, giardiasis), bacterial vaginosis, anaerobic bacterial infections | |
| **Daptomycin** | GP, including MRSA and VRE | Hypothesized to bind to cell wall and form channels leading to intracellular $K^+$ depletion | Skeletal muscle injury at high doses (elevated CPK) Peripheral neuropathy | Bacteremia, endocarditis, skin and soft tissue, and other infections due to resistant GP infections including MRSA and VRE | Known hypersensitivity<br><br>Inactivated by surfactant, therefore not used in MRSA pneumonia Tx |

**Table 29. Antibiotics** (continued)

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Indications | Contraindications |
|---|---|---|---|---|---|
| **ANTI-METABOLITE** | | | | | |
| **Trimethoprim-Sulfamethoxazole (TMP/SMX)** (Septra®, Bactrim®) | GP, especially *S. aureus* (including most MRSA)<br>GN: enteric<br>*Nocardia*<br>Other: *Pneumocystis, Toxoplasmosis* | Inhibits folic acid pathway (TMP inhibits DHFR and SMX competes with PABA) | Hepatitis<br>Stevens-Johnson syndrome<br>Bone marrow suppression<br>Hyperkalemia<br>Drug toxicity (increases free levels of many drugs, including glyburide, warfarin) | Susceptible UTI, RTI, GI infections, skin and soft tissue infections caused by staphylococcal species, treatment and prophylaxis of *P. jiroveci* pneumonia | Hypersensitivity to TMP-SMX, sulfa drugs |
| **nitrofurantoin** (MacroBID®, (Macrodantin®) | *Enterococcus, S. saprophyticus*<br>GN (coliforms) | Reactive metabolites inhibit ribosomal protein synthesis | Cholestasis, hepatitis<br>Hemolysis if G6PD deficiency<br>Interstitial lung disease with chronic use | Lower UTI; not pyelonephritis or bacteremia | Hypersensitivity to nitrofurantoin<br>Anuria, oliguria, or significant renal impairment<br>Pregnant patients during labour and delivery or when labour imminent<br>Infants <1 mo of age |
| **ANTI-MYCOBACTERIALS** | | | | | |
| isoniazid (INH) | *Mycobacteria* | Inhibits mycolic acid synthesis | Hepatotoxicity<br>Hepatitis<br>Drug-induced SLE<br>Peripheral neuropathy | Part of multidrug treatment for active TB, alone for treatment of latent TB | Drug-induced hepatitis or acute liver disease |
| rifampin (RIF) | *Mycobacteria* | Inhibits RNA polymerase | Hepatotoxicity P450 enzyme inducer<br>Orange tears, saliva, urine | Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment of other mycobacterial infections | Jaundice<br>Not to be used monotherapy (except for prophylaxis) |
| ethambutol | *Mycobacteria* | Inhibits mycolic acid synthesis | Loss of central and colour vision<br>Neuropathy | Part of multidrug treatment for active TB and other mycobacterial infections | Renal failure |
| pyrazinamide (PZA) | *Mycobacteria* | Unknown | Hepatotoxicity<br>Gout<br>Gastric irritation | Part of multidrug treatment for active TB | Severe hepatic damage or acute liver disease<br>Patients with acute gout |
| **SULFONES** | | | | | |
| dapsone<br>sulfoxone | *M. leprae, P. jiroveci, Toxoplasma* | Inhibit folic acid synthesis by competition with PABA | Rash<br>Drug fever<br>Agranulocytosis | Part of multidrug treatment for *M. leprae*, part of treatment for *P. jiroveci* pneumonia (with TMP), *P. jiroveci* pneumonia prophylaxis, toxoplasmosis prophylaxis with pyrimethamine | |

**Table 30. Antibiotics for Selected Bacteria**

| *Pseudomonas* | *S. aureus* | *Enterococcus* | *H. influenzae* | Anaerobes |
|---|---|---|---|---|
| ciprofloxacin | cloxacillin (MSSA) | ampicillin | amoxicillin-clavulanate | metronidazole |
| gentamicin, tobramycin amikacin | 1° cephalosporin (MSSA) | amoxicillin | 2°/3° cephalosporin | clindamycin |
| piperacillin/ tazobactam | clindamycin | vancomycin | macrolides (clarithromycin, azithromycin) | amoxicillin-clavulanate |
| ceftazidime | cotrimoxazole (including MRSA) | nitrofurantoin (lower UTI) | levofloxacin | cefoxitin |
| cefipime | vancomycin (including MRSA) | linezolid for VRE | moxifloxacin | piperacillin/tazobactam |
| meropenem, imipenem | linezolid (including MRSA) | daptomycin for VRE | | moxifloxacin |
| | daptomycin (including MRSA) | tigecycline for VRE | | ertapenem, imipenem, meropenem |
| | tigecycline (including MRSA) | | | |
| | doxycycline (MSSA/MRSA) | penicillin | | |
| | | imipenem | | |

**Rifampin**
- Good adjunct for treating prosthetic device infection (bacterial biofilm)
- Always used in combination with other antibiotics to reduce emergence of resistance

# Antivirals

**Table 31. Antivirals**

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Contraindications |
|---|---|---|---|---|
| **ANTI-HERPESVIRUS** | | | | |
| acyclovir<br>valacyclovir (Valtrex®)<br>(prodrug of acyclovir) | HSV-1,2<br>VZV | Guanosine analog inhibits viral DNA polymerase | PO well-tolerated<br>IV: nephrotoxicity, CNS | Hypersensitivity to acyclovir or valacyclovir |
| famciclovir (Famvir®)<br>penciclovir | HSV-1,2<br>VZV | See above | Headache, nausea | Hypersensitivity to famciclovir or penciclovir |
| ganciclovir (Cytovene®)<br>valganciclovir (prodrug of ganciclovir) | CMV<br>HSV-1,2, VZV, HHV-6, EBV | See above | Heme: neutropenia, thrombocytopenia, anemia | Hypersensitivity to ganciclovir or valganciclovir<br>Possible cross-hypersensitivity between acyclovir and valacyclovir |
| Foscarnet | CMV<br>Acyclovir-resistant HSV, VZV | Pyrophosphate analog inhibits viral DNA polymerase | Nephrotoxicity<br>Anemia<br>Electrolyte disturbance | Hypersensitivity to foscarnet |
| **OTHER ANTIVIRALS** | | | | |
| (pegylated) interferon-α-2a or-2b | Chronic hepatitis B or C HPV | Inhibits viral protein synthesis | "Flu-like" syndrome<br>Depression<br>Bone marrow suppression | Hypersensitivity to any interferon<br>Cannot use in combination with ribavirin if renal impairment |
| ribavirin (Virazole®) | Chronic hepatitis C RSV Lassa fever | Guanosine analog with multiple postulated mechanisms of action | Hemolytic anemia<br>Rash, conjunctivitis<br>Highly teratogenic | Pregnancy, women who may become pregnant or their partners<br>Renal impairment |
| Cidofovir | Adenovirus<br>CMV retinitis<br>Acyclovir and foscarnet resistant HSV | Deoxycitidine analogue Inhibits DNA synthesis | Nephrotoxicity (proximal tubule dysfunction) | Renal failure; probenecid can reduce renal toxicity |
| lamivudine (Epivir®) | Chronic hepatitis B HIV | See *HIV and AIDS*, ID25 | See *HIV and AIDS*, ID25 | See *HIV and AIDS*, ID25 |
| Tenofovir | Chronic hepatitis B HIV | See *HIV and AIDS*, ID25 | See *HIV and AIDS*, ID25 | See *HIV and AIDS*, ID25 |
| Neuraminidase inhibitors:<br>zanamivir (Relenza®)<br>oseltamivir (Tamiflu®) | Influenza A and B: treatment and prophylaxis | Inhibits neuraminidase, an enzyme required for release of virus from infected cells and prevention of viral aggregation | GI: nausea/vomiting, diarrhea<br>Bronchospasm in zanamavir | Hypersensitivity to the neuraminidase inhibitors |

# Antifungals

**Table 32. Antifungals**

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Contraindications |
|---|---|---|---|---|
| **POLYENES** | | | | |
| amphotericin B | Endemic mycoses:<br>Histoplasmosis<br>Blastomycosis<br>Coccidioidomycosis<br>Pulmonary:<br>Aspergillosis<br>CNS:<br>*Cryptococcus* | A polyene antimicrobial: inserts into fungal cytoplasmic membrane causing altered membrane permeability and cell death | Nephrotoxicity<br>Hypo/hyperkalemia<br>Infusion reactions: chills, fevers, headache<br>Peripheral phlebitis | Renal impairment |
| nystatin (oral, topical) | Candidiasis: mucocutaneous, GI, oral (thrush), vaginal | See above<br>Not absorbed from the GI tract | GI: nausea/vomiting, diarrhea<br>Highly toxic if given IV | |
| **IMIDAZOLES** | | | | |
| clotrimazole (Canesten®) | Oral and vulvovaginal candidiasis Dermatomycoses | All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability | Pruritis, skin irritation | |
| miconazole (Monistat®, Micozole®) | Vulvovaginal candidiasis<br>Dermatomycoses | | Vaginal burning<br>Nausea/vomiting | |
| ketoconazole (Nizoral®) | Dermatomycoses<br>Seborrheic dermatitis | | Pruritis, skin irritation GI nonspecific Results in decreased androgen and testosterone synthesis | Cross-sensitivity with other azoles possible<br>Hepatic dysfunction<br>Pregnant women or those that may become pregnant |

**Table 32. Antifungals** (continued)

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Contraindications |
|---|---|---|---|---|
| **TRIAZOLES** | | | | |
| fluconazole (Diflucan®) | Candida infections (mucosal and invasive)<br>Cryptococcal meningitis (step-down therapy) | All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability | Elevated liver enzymes GI nonspecific | Cross-sensitivity with other azoles unknown |
| itraconazole (Sporanox®) | Sporotrichosis Onychomycoses<br>Endemic mycoses:<br>Histoplasmosis<br>Blastomycosis<br>Coccidioidomycosis | | Elevated liver enzymes Rash GI nonspecific HTN Hyperkalemia Peripheral edema | Cross-sensitivity with other azoles unknown<br>Severe ventricular dysfunction |
| voriconazole (Vfend®) | Aspergillosis<br>Candidiasis | | Visual disturbance (30%)<br>Hepatotoxicity<br>Cutaneous photosensitivity<br>Cutaneous squamous cell carcinoma with long-term use in immunosuppressed patients<br>Prolonged QT Periostitis<br>Neurologic toxicity | Cross-sensitivity with other azoles unknown<br>May avoid or alter doses if co-administered with other CYP3A4 substrates, rifampin, carbamazepine, long-acting barbiturates, ritonavir, efavirenz, sirolimus, rifabutin, ergot alkaloids |
| posaconazole (Posanol®, Noxafil®) | Candidiasis<br>Aspergillosis<br>Mucormycosis | | Elevated liver enzymes<br>Headache<br>Prolonged QT | Coadministration of cisapride, ergot alkaloids, pimozide, quinidine, or sirolimus |
| **ALLYLAMINES** | | | | |
| terbinafine (Lamisil®) | Dermatomycoses<br>Onychomycoses | Inhibits enzyme needed for ergosterol synthesis | Rash, local irritation GI nonspecific, transaminitis | Active liver disease |
| **ECHINOCANDINS** | | | | |
| caspofungin<br>micafungin<br>anidulafungin | Refractory aspergillosis, candidemia (azole-resistant) | Inhibits 1-3 β-D-glucan synthesis (needed for fungal cell wall) | Hepatotoxicity Infusion and injection site reactions | |

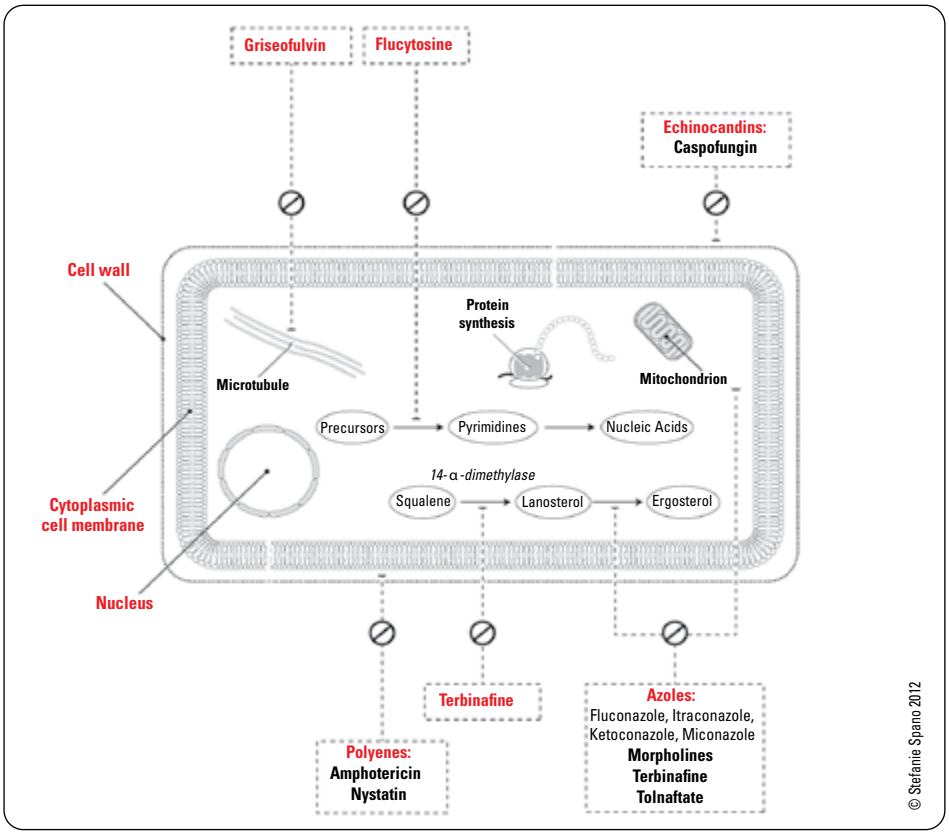

**Figure 19. Mechanism of action of antifungals**

# Antiparasitics

**Table 33. Antiparasitics**

| Class and Drugs | Coverage | Mechanism of Action | Adverse Effects | Contraindications |
|---|---|---|---|---|
| **ANTIMALARIALS** | | | | |
| chloroquine | Malaria: treatment of erythrocytic phase of all five species of *Plasmodium* that infect humans Note: High resistance of *P. falciparum* and *P. vivax* in certain geographic areas | Inhibits parasite heme polymerase | CNS: blurred vision, retinopathy, dizziness<br>Nonspecific GI (rare with prophylaxis) | Hypersensitivity to chloroquine or other 4-aminoquinoline<br>Retinal or visual field changes due to 4-aminoquinoline |
| quinine | Malaria: treatment of all five species of *Plasmodium* that infect humans, including chloroquine-resistant *P. falciparum* | | Cinchonism: ears (tinnitus, vertigo), eyes (visual disturbance), GI (nausea/vomiting, diarrhea), CNS (headache, fever)<br>Hypoglycemia | Hypersensitivity to quinine, may have cross-sensitivity with quinidine<br>Patients with G6PD deficiency, tinnitus, optic neuritis, hypoglycemia, history of blackwater fever or thrombocytopenic purpura due to quinine use |
| mefloquine (Lariam®) | Malaria: prophylaxis | | CNS/Psych: irritability, nightmares, psychoses, suicide, depression, seizures, headache | History of seizures, psychosis, severe anxiety or depression |
| primaquine | Malaria: treatment of liver hypnozoites of *P. vivax* and *P. ovale*; prophylaxis of all *Plasmodium* spp. *Pneumocystis jiroveci* (with clindamycin) | Interferes with mitochondrial function | Hemolytic anemia in G6PD deficient<br>GI upset (take with food) | GI nonspecific<br>G6PD deficiency<br>Concurrent or recent use of quinacrine<br>Pregnancy |
| atovaquone/proguanil (Malarone®) | Malaria: treatment and prophylaxis of *P. falciparum* | Inhibits mitochondrial electron transport and dihydrofolate reductase | Nausea/vomiting, anorexia, diarrhea, abdominal pain (take with food) | Hypersensitivity to atovaquone or proguanil<br>Severe renal impairment |
| artemisinin derivatives (artemether, artesunate, etc.)<br>Note: marketed primarily in endemic countries | Malaria: treatment of all *Plasmodium* spp.<br>Severe malaria (IV artesunate)<br>Typically used in combination with a longer-acting agent from above | Binds iron, leading to formation of free radicals that damage parasite proteins | Transient neurologic deficits (nystagmus, balance disturbance)<br>Transient neutropenia (at high doses of oral artesunate)<br>Delayed hemolysis | Hypersensitivity to artemisinins |
| **OTHER ANTI-PROTOZOAL** | | | | |
| iodoquinol (Diodoquin®) | Amoebiasis: *E. histolytica, Dientamoeba fragilis, Balantidium coli, Blastocystis hominis* | Contact amoebicide that acts in intestinal lumen by uncertain mechanism | GI: nausea/vomiting, diarrhea, abdominal pain CNS: headache, seizures, encephalitis | Hypersensitivity to any 8-hydroxy-quinoline or iodine<br>Patients with hepatic damage or optic neuropathy<br>Pregnancy |
| metronidazole | Amoebiasis, *T. vaginalis,* giardiasis, *D. fragilis* | See *Antibiotics*, ID48 | | |
| nitazoxanide | *Cryptosporidium*, giardiasis, cyclosporiasis | Interferes with parasite anaerobic metabolism | Nausea/vomiting, diarrhea, abdominal pain, headache | Hypersensitivity to nitazoxanide |
| **ANTI-HELMINTHICS** | | | | |
| praziquantel | *Schistosomiasis* and other flukes<br>Tapeworms | Increases $Ca^{2+}$ permeability of helminth cell membrane, causing paralysis and detachment | Nausea/vomiting, fever, dizziness | Ocular cysticercosis |
| albendazole | Intestinal roundworms<br>*Neurocysticercosis*<br>*Echinococcus*<br>Hydatid disease | Inhibits glucose uptake into susceptible parasites | Elevated liver enzymes<br>Alopecia<br>GI nonspecific<br>Agranulocytosis | Pregnancy<br>Ocular cysticercosis or intraventricular cysticercosis |
| mebendazole (Vermox®) | Intestinal roundworms: pinworm, whipworm, hookworm, roundworm (e.g. *Ascaris*) | Inhibits microtubule formation and glucose uptake | Nonspecific GI | Pregnancy, infants |
| ivermectin | *Strongyloidiasis*<br>*Onchocerciasis*<br>Scabies | Interferes with polarization of nerve and muscles cells in susceptible parasites leading to paralysis | Nausea, bloating, diarrhea, myalgias, lightheadedness, headache | Hypersensitivity to ivermectin<br>Pregnancy |
| diethylcarbamazine | *Wuchereria bancrofti*<br>*Loa loa* | | Anorexia, nausea/vomiting, headache, drowsiness, encephalitis, retinal hemorrhage<br>Mazzotti reaction if coinfected with onchocerciasis | Pregnancy<br>Onchocerciasis |

| US | ultrasound |
| WES | whole exome sequencing |

# Introduction to Genetics

## Common Terms

- **penetrance**: probability that a gene variant/mutation is observably expressed in an individual that carries it
- **expressivity**: extent of gene expression – refers to the range of variation seen in a phenotype
- **genetic heterogeneity**: a common phenotype/genetic disorder caused by more than one allele or locus mutation
- **phenotypic heterogeneity**: mutations in the same gene resulting in multiple diverse clinical manifestations and degrees of severity
- **mosaicism**: presence of two or more genotypes (e.g. chromosome patterns or gene variants) in the cells of the same person
- **nondisjunction**: an error in cell division where the chromosomes fail to segregate, so both pass to the same daughter cell
- **uniparental disomy**: two full or partial copies of a chromosome from one parental origin and no corresponding full/partial chromosome from the other parent

## Copy Number Variation

- duplication or deletion events that result in variation in the number of genomic sections between individuals. CNVs can be part of normal spectrum of genetic variation
  - decrease: deletion of a chromosomal region, leaving only one copy of the genetic material in that region (e.g. 22q11.2 deletion syndrome due to deletion on one copy of chromosome 22) or leaving no copies in the case of X chromosome material in a male
  - increase: duplication of a chromosomal region, resulting in more than two copies of the genetic material in that region (e.g. Potocki-Lupski syndrome due to duplication of chromosome 17p11.2) or more than one copy in the case of X chromosome material in a male

## Mendelian Inheritance

- traits or disorders determined by a gene at a single locus
- autosomal inheritance: disorder is caused by mutations in genes on one of 22 pairs of autosomes (chromosomes 1-22)
  - autosomal dominant: one copy of a gene with a mutation is enough to cause a trait/disorder
  - autosomal recessive: both copies of a gene must have mutations to cause a trait/disorder; one copy of mutation = carrier
- x-linked inheritance: when disease is caused by mutations in a gene on the X chromosome; generally results in a trait/disorder that is seen more commonly or with greater severity in males than females

## Triplet Repeat Expansions

- disorders where the number of trinucleotide repeats in certain genes exceeds the normal number and result in altered gene expression or production of an abnormal protein
  - these disorders can demonstrate genetic anticipation, where signs and symptoms appear more severe and at an earlier age from each generation to the next
  - length of expansion segment is often proportional to severity of clinical phenotype
- examples: Fragile X syndrome, Huntington disease

## Imprinting Disorders

- imprinted genes are expressed entirely from either the maternal or paternal allele, depending on the gene (parent-of-origin gene expression)
- occur when a mutation disrupts the normally expressed allele of imprinted gene, or through uniparental disomy of the normally silenced allele
- examples: Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome

## Mitochondrial Disorders

- disorders caused by mutations in mitochondrial DNA or nuclear genes whose protein products are important for mitochondrial function. High phenotypic heterogeneity

- mother passes on the defect to all of her children; father cannot pass on defect since embryo only receives mitochondria from the mother (in the egg)
- examples: mitochondrial enceophalomyopathy and lactic acidosis with stoke-like episodes (MELAS) syndrome, Leigh syndrome, Kearns-Sayre syndrome, myoclonic epilepsy with ragged red fibres (MERRF) syndrome

# Pedigrees

- diagrams of a family tree that show the pattern/distribution of phenotypes for a genetic disorder within that family, often across multiple generations

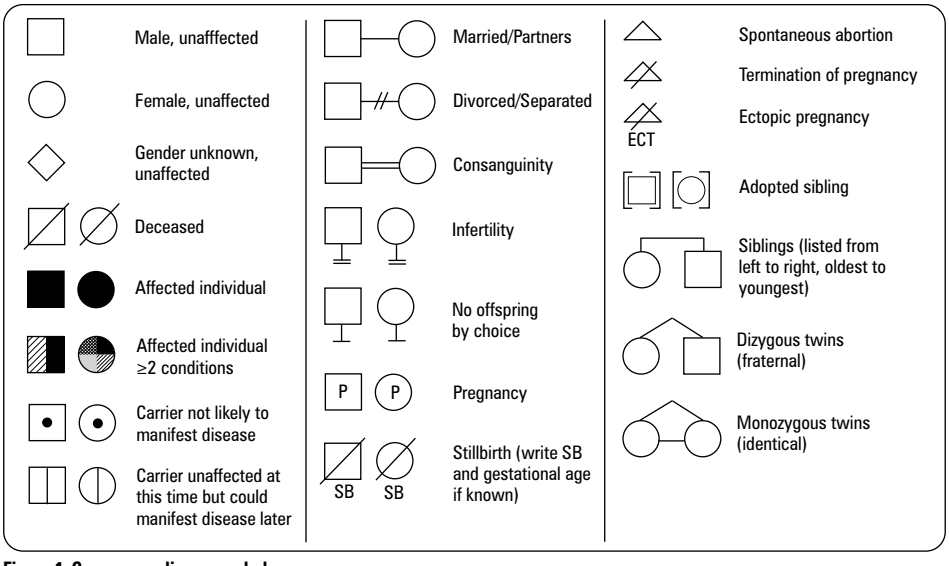

**Figure 1. Common pedigree symbols**

# Genetic Testing and Counselling

## Common Terms

- presymptomatic genetic testing: to determine whether individuals without current symptoms, but with a known family history of a genetic disease, carry the mutation associated with the disease
- linkage studies/indirect DNA studies: studies that look at markers (known DNA sequences) around the gene in question, due to an inability to study the gene itself
- newborn screening: performed within first few days of life to detect treatable, potentially fatal disorders before symptoms arise to allow for early therapy
- preconception genetic counselling: pre-pregnancy examination to assess risk of having a child with an inherited condition

**Table 1. Common Genetic Tests**

| Test | Karyotype | FISH | Microarray Analysis | Sanger Sequencing | NGS/WES |
|---|---|---|---|---|---|
| **Technique** | Microscopic analysis of chromosomes with a special stain that shows large changes in the number or structure of chromosomes; can detect large CNVs | A fluorescent-tagged DNA probe used to identify a gain, loss or rearrangement of chromosomal material | Array comparative genomic hybridization (CGH): a collection of DNA probes attached to a solid surface to which test DNA hybridizes in order to determine copy number of DNA regions | A method of DNA sequencing which is based on the selective incorporation of chain-terminating nucleotides during replication | High-throughput method to sequence multiple genes, or whole exome |
| **Uses/Indications** | Useful to identify major aneuploidies, structural chromosomal rearrangements, chromosomal changes related to hematological conditions, or other genetic diseases related to chromosome structure | Can confirm the presence or absence of specific DNA sequences, and localize them. May be used to detect aneuploidies or balanced rearrangements, in gene mapping or identification of oncogenes, and in identification of circulating tumour cells | Microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome Commonly indicated when there is developmental delay/ autism OR two or more congenital anomalies | The "gold-standard" method for identification of single nucletotide variants in the gene(s) known to cause suspected syndrome | NGS is useful for multi-gene test panels when multiple genes are associated to a given indication. WES is useful when genetic syndrome is suspected, but the diagnosis is unclear |

**Meta-analysis of the Diagnostic and Clinical Utility of Genome and Exome Sequencing and Chromosomal Microarray in Children**
Genomic Med 2018;3:16
**Objective**: To compare the diagnostic and clinical utility of genome and whole-exome sequencing to the chromosomal microarray.
**Methods**: A systematic review and meta-analysis of the literature.
**Results**: 37 studies were included (20, 068 children). Diagnostic utility of whole-genome sequencing (0.41, 95% CI 0.34-0.48) and whole-exome sequencing (0.36, 95% CI 0.33-0.40) were greater than chromosomal microarray (0.10, 95% CI 0.08-0.12). The clinical utility of whole-genome sequencing (0.27, 95% CI 0.17-0.40) and whole-exome sequencing (0.17, 95% 0.12-0.24) were higher than chromosomal microarray (0.06, 95% CI 0.05-0.07) and this difference was significant for whole genome sequencing vs chromosomal microarray ($p<0.0001$).
**Conclusion**: The diagnostic and clinical utility of whole genome and exome sequencing is greater than chromosomal microarray.

**Table 2. Prenatal and Newborn Screening Tests**

| Test | FTS | Enhanced FTS | IPS | NIPT | Fetal Anatomy Scan | Newborn Screening |
|---|---|---|---|---|---|---|
| **Technique/ Indications** | Biochemistry (β-hCG, PAPP-A) US estimate of gestational age and measurement of nuchal translucency | Biochemistry (β-hCG, PAPP-A, AFP, placental growth factor) also uses nuchal translucency measurement and maternal age | Use results from FTS and combine with additional biomarkers (inhibin A, unconjugated estradiol, AFP, 2nd trimester β-hCG) | Uses cell-free DNA from placenta that circulates in maternal blood<br><br>Consider if: advanced maternal age (≥40), abnormal FTS/IPS screen, previous trisomy, NT ≥3.5 mm | Ultrasound | Heel puncture to collect blood, many conditions tested by tandem-mass spectrometry<br><br>Performed on all newborns in Canada with varying conditions screened depending on provinces |
| **Gestational Age (GA)** | 11 and 14 wk GA | 11 and 13 wk GA | 15-21 wk GA | 9-10 wk GA | 18-20 wk GA | After birth |
| **Uses** | Screens for trisomy 21 and 18, sensitivity80-85% | Screens for trisomy 21 and 18, sensitivity 85-90% | Screens for ONTD, trisomy 21 and 18; improved sensitivity, reduced false positive rate compared to FTS (sensitivity for Down's syndrome 85-90%) | Screens for trisomy 21, 13 and 18, and sex chromosome aneuploidies; improved sensitivity and specificity compared to IPS/FTS | Screens for congenital anomalies and soft markers that may suggest a genetic syndrome | Screens for treatable disorders (e.g. CF, congenital hypothyroidism, congenital adrenal hyperplasia, SCID, hemoglobinopathies, metabolic diseases, (e.g. PKU), etc.) |

# Dysmorphisms

## Congenital Anomalies

### Minor and Major Anomalies
- minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
- major anomaly: anomaly that creates significant medical, surgical or cosmetic problems for the patient

### Mechanisms for Anomalies
- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. skeletal dysplasia)

### Multiple Anomalies
- association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not known to have a single etiology (e.g. VACTERL)
- sequence: related anomalies that originate from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence or Pierre-Robin sequence)
- syndrome: a pattern of anomalies that occur together and are known or thought to have a single cause (e.g. CHARGE syndrome)

**VACTERL Association**
- **V** **V**ertebral dysgenesis
- **A** **A**nal atresia (imperforate anus) ± fistula
- **C** **C**ardiac anomalies
- **T-E** **T**racheo**E**sophageal fistula ± esophageal atresia
- **R** **R**enal anomalies
- **L** **L**imb anomalies

## Approach to the Dysmorphic Child

- congenital abnormalities are the most common cause of infant death in developed countries

### General Approach to the Dysmorphic Child
- Are the anomalies major or minor?
- What is the mechanism underlying the anomaly?
- Do the anomalies fit as part of an association, sequence, or syndrome?

### History
- prenatal/obstetrical history (see Obstetrics, OB4) with particular attention to potential teratogenic exposures, developmental history (see Pediatrics, P23), and past medical history
- complete three generation family pedigree: health history, consanguinity, multiple miscarriages/ stillbirths, neonatal deaths, congenital defects, intellectual disability/autism, ethnicity

## Physical Exam

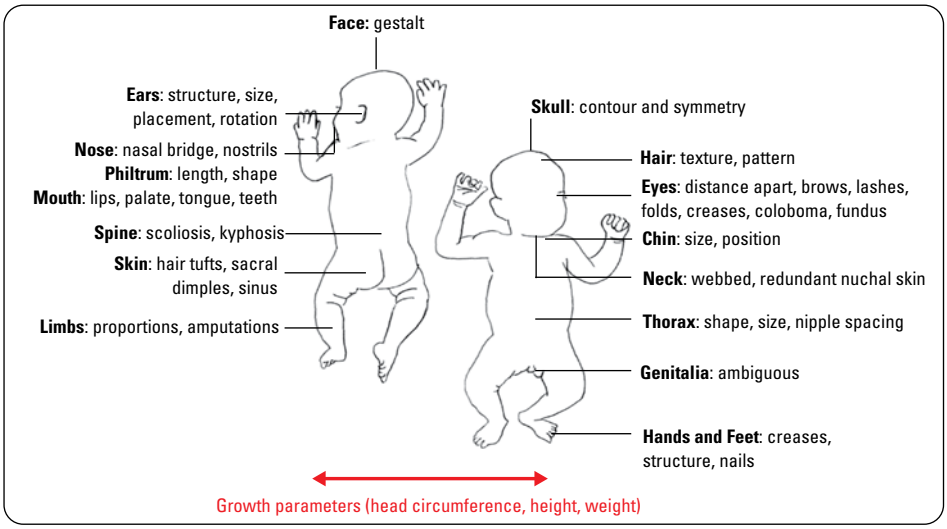

**Figure 2. Physical exam in genetic assessment of a child**

## Investigations

- screening for TORCH infections
- serial photographs if child is older
- x-rays for bony abnormalities
- abdominal ultrasound and echocardiography to rule out structural abnormalities of organs
- cytogenetic studies
  - chromosomal microarray analysis (array CGH) if developmental delay/autism OR two or more congenital anomalies
  - FISH if aneuploidy syndrome (e.g. trisomy 13, 18, or 21) suspected
  - karyotype to consider only if a known aneuploidy syndrome is recognized or if there is a family history of a chromosomal rearrangement such as a translocation
- biochemistry: various biochemical tests, specific enzyme assays (eg. for lysosomal storage diseases)
- single gene testing, multi-gene panel testing, WES

Check the umbilical cord for 2 arteries and 1 vein. The presence of a single umbilical artery may be associated with other congenital anomalies

## Management

- recurrence risk and prenatal counselling
- referral for specialized pediatric or genetic care for symptomatic management
- specific treatments are available for certain metabolic disorders and genetic syndromes
  - metabolic disorders: enzyme replacement therapy, substrate reduction therapy (e.g. low-protein diet in PKU patients)
  - genetic syndromes: e.g. mTOR inhibitors in tuberous sclerosis

# Syndromes and Diseases

### Table 3. Common Chromosomal Aneuploidy Syndromes

| | Trisomy 21 | Trisomy 18 | Trisomy 13 |
|---|---|---|---|
| **Disease** | Down syndrome | Edwards syndrome | Patau syndrome |
| **Incidence** | 1:600-800 births<br>Most common abnormality of autosomal chromosomes<br>Rises with advanced maternal age from 1:1500 at age 20 to 1:20 by age 45 | 1:6000 live births<br>F:M = 3:1 | 1:10,000 live births |
| **Cranium/Brain** | Mild microcephaly, flat occiput, third fontanelle, brachycephaly | Microcephaly, prominent occiput | Microcephaly, sloping forehead, scalp defect, holoprosencephaly |
| **Eyes** | Upslanting palpebral fissures, epicanthal folds, speckled iris (Brushfield spots), refractive errors (myopia), acquired cataracts, nystagmus, strabismus | Microphthalmia, hypotelorism, iris coloboma, retinal anomalies | Microphthalmia, corneal abnormalities |
| **Ears** | Low-set, small, overfolded upper helix, frequent acute otitis media, hearing loss | Low-set, malformed | Low-set, malformed |
| **Facial Features** | Protruding tongue, large cheeks, low flat nasal bridge, small nose | Cleft lip/palate<br>Small mouth, micrognathia | 60-80% cleft lip and palate |
| **Skeletal/MSK** | Short stature<br>Excess nuchal skin<br>Joint hyperflexibility (80%) including dysplastic hips, vertebral anomalies, atlantoaxial instability | Intrauterine growth restriction<br>Clenched fist with overlapping digits, hypoplastic nails, clinodactyly | Small head size<br>Polydactyly |
| **Cardiac Defect** | 50%, particularly atrioventricular septal defect | 60% (ventricular septal defect, patent ductus arteriosus, atrial septal defect) | 80% (ventricular septal defect, patent ductus arteriosus, atrial septal defect) |
| **GI** | Duodenal/esophageal/anal atresia, tracheoesophageal fistula, Hirschsprung's disease, chronic constipation | Hernia, tracheoesophageal fistula | |
| **GU** | Cryptorchidism, rarely fertile | Polycystic kidneys, cryptorchidism | Polycystic kidneys |
| **CNS** | Hypotonia at birth<br>Low IQ, developmental delay, hearing problems<br>Onset of Alzheimer's disease in 40s | Hypertonia | Hypo- or hypertonia<br>Seizures, deafness |
| **Other Features** | Single transverse palmar crease, clinodactyly and absent middle phalanx of the 5th finger<br>1% lifetime risk of leukemia<br>Polycythemia<br>Hypothyroidism | Small for gestational age<br>Rocker-bottom feet | Single umbilical artery<br>Midline anomalies: scalp, holoprocencephaly, palate, heart, umbilicus, anus |
| **Prognosis/ Management** | Long-term management per AAP Guidelines (Health Supervision of Children with Down Syndrome): CBC, Echo, yearly thyroid test, atlanto-occipital x-ray at 2 yr, sleep study, hearing test and ophthalmology assessment | 13% 1 year survival, 10% ten year survival<br>Profound intellectual disability in survivors | 20% 1 year survival, 13% ten year survival<br>Profound intellectual disability in survivors |

### Table 4. Common Genetic Disorders Involving the Sex Chromosomes

| | Fragile X Syndrome | Klinefelter Syndrome | Turner Syndrome |
|---|---|---|---|
| **Genotype** | CGG trinucleotide repeat expansion in *FMR1* gene on X chromosome | 47,XXY (most common)<br>48,XXXY, 49,XXXXY | 45,X (most common) |
| **Incidence** | 1:3600 males, 1:6000 females<br>Most common heritable cause of intellectual disability in boys | 1:1000 live male births<br>Increased risk with advanced maternal age | 1:4000 live female births<br>Risk not increased with advanced maternal age |
| **Phenotype** | Overgrowth: macrocephaly, prominent jaw, forehead, and nasal bridge with long and thin face, large protuberant ears, macroorchidism, hyperextensibility, and high arched palate<br>Complications: seizures, scoliosis, mitral valve prolapse<br>Premutation carriers (males more often than females) may demonstrate tremor/ataxia syndrome in later life | Tall, slim, underweight<br>No features pre-puberty<br>Post-puberty: variable learning/behavioural difficulties, long limbs, gynecomastia, lack of facial hair | Short stature, short webbed neck, low posterior hair line, wide carrying angle<br>Broad chest, widely spaced nipples<br>Lymphedema of hands and/or feet, cystic hygroma in newborn with polyhydramnios, lung hypoplasia<br>Coarctation of aorta, bicuspid aortic valve<br>Renal and cardiovascular abnormalities, increased risk of HTN<br>Less severe spectrum with mosaic |
| **IQ and Behaviour** | Mild to moderate intellectual disability, 20% of affected males have normal IQ<br>ADHD and/or autism<br>Females with full mutation may show milder intellectual impairment | Mild intellectual disability or learning difficulties<br>Behavioural or psychiatric disorders – anxiety, shyness, aggressive and impulsive behaviour acts | Typically normal intelligence |
| **Gonad and Reproductive Function** | Premutation carrier females at risk of developing premature ovarian failure | Infertility due to hypergonadotropic hypogonadism | Streak ovaries with deficient follicles, infertility, primary amenorrhea, impaired development of secondary sexual characteristics |
| **Diagnosis** | Molecular testing of FMR1 gene: PCR and/or Southern blot analysis of trinucleotide repeat length | Karyotype | Karyotype |

**Table 5. Examples of Other Genetic Syndromes**

| | 22q11.2 Deletion Syndrome | Prader-Willi Syndrome | Angelman Syndrome | Noonan Syndrome | CHARGE Syndrome | Marfan Syndrome |
|---|---|---|---|---|---|---|
| **Genotype** | Microdeletions of chromosome region 22q11.2 | Lack of expression of genes on paternal chromosome 15q11-13 due to deletion, maternal uniparental disomy of chromosome 15, or imprinting defect | Lack of expression of genes on maternal chromosome 15q11-13 due to deletion, paternal uniparental disomy of chromosome 15, or an imprinting defect<br>Rarely due to mutations in *UBE3A* | Autosomal dominant with variable expression, mutations in RAS/MPK pathway genes ("RASopathies") | 2/3 of children with CHARGE have been found to have a CHD7 mutation on chromosome 8 | Mutations in FBN1 gene |
| **Incidence** | 1:4000; second most common genetic diagnosis (next to Down syndrome) | 1:15,000 | 1:10,000 | 1:2000 | 1:10,000 | 1:3000-5000 |
| **Clinical Features** | **"CATCH 22"**<br>**C**yanotic CHD<br>**A**nomalies: craniofacial anomalies, micrognathia and low set ears<br>**T**hymic hypoplasia: immunodeficiency<br>**C**ognitive impairment<br>**H**ypoparathyroidism, hypocalcemia<br>**22**q11 microdeletions<br>High risk for schizophrenia and other psych disorders | **"$H_3O$": H**ypotonia and weakness, **H**ypogonadism, obsessive **H**yperphagia, **O**besity<br>Short stature, almond-shaped eyes, small hands and feet with tapering of fingers<br>Developmental delay (variable)<br>Hypopigmentation, type 2 DM | Ataxia with severe intellectual disability, seizures, tremulousness, midface hypoplasia, large mouth, fair hair, inappropriately happy demeanour/laughter | Short stature, webbed neck, hypertelorism, low set ears, epicanthal folds, ptosis, pectus excavatum<br>Right-sided CHD, pulmonary stenosis<br>Increased risk of hematological cancers, cardiomyopathy, moderate intellectual disability, delayed puberty | **"CHARGE"**<br>**C** **C**oloboma<br>**H** congenital **H**eart disease<br>**A** choanal **A**tresia<br>**R** mental **R**etardation<br>**G** **G**U anomalies<br>**E** **E**ar anomalies | Tall and slender build, disproportionately long limbs and digits, aortic dilatation, lens detachment, pneumothoraces |

**Table 6. Examples of Familial Cancer Syndromes**

| Syndrome | Gene | Associated Cancers | Screening and Monitoring |
|---|---|---|---|
| **Li-Fraumeni Syndrome** | *TP53* | Breast, osteosarcoma, leukemia, soft tissue carcinoma, and numerous other cancers | **Women:**<br>Age 20-29: annual breast MRI<br>Age 30-75: annual breast MRI and mammogram<br>**Men and Women:**<br>Age 18: annual dermatologic examination<br>Age 25: colonoscopy and upper endoscopy every 2-5 yr<br>*(Moderate recommendation)* |
| **Lynch Syndrome (HNPCC)** | *MSH2, MLH1, MSH6, PMS2, EPCAM* | Colorectal, endometrial, ovarian, renal, pancreatic, liver/biliary duct, stomach, brain, breast | Age 20-25 (or 2-5 yr younger than CRC in family): colonoscopy every 1-2 yr<br>Age 30 yr (MSH6) and 35 (PMS2): colonoscopy every 1-2 yr<br>*(Strong recommendation)* |
| **Familial Adenomatous Polyposis (FAP)** | *APC* | Colorectal, small intestine/stomach tumours | Age 10: sigmoidoscopy or colonoscopy every 1-2 yr, colonoscopy once polyps develop<br>*(Strong recommendation)* |
| **Hereditary Breast and Ovarian Cancer Syndrome** | *BRCA1, BRCA2* | Female: breast, ovarian, pancreatic<br>Male: prostate, breast, pancreatic | Age 25-65: annual breast MRI<br>Age 30: annual breast MRI and mammograms<br>*(Strong recommendation)* |
| **Von Hippel-Lindau Syndrome** | *VHL* | Kidney + tumours (e.g. pheochromocytoma) | Age 2: annual physical examination, annual ophthalmologic examination, consider annual catecholamine assessment<br>Consider baseline audiometry at age of school entry<br>Ages 12, 15, and 18: MRI of brain stem, spine, and abdomen, with abdominal ultrasound in alternating years<br>Age 20: MRI every 2 yr<br>*(Expert opinion)* |
| **Cowden Syndrome** | *PTEN* | Breast, thyroid, endometrial | **Women:**<br>Age 30 (or 5-10 yr before earliest breast cancer in the family): annual mammography<br>Age 30: consider random annual endometrial biopsy and/or ultrasound<br>**Men and Women:**<br>At diagnosis: annual thyroid ultrasound<br>Children: evaluation for neurodevelopmental disorders<br>Age 18: annual comprehensive physical exam<br>Age 30-35: colonoscopy every 5 yr<br>*(Moderate recommendation)* |
| **Neurofibromatosis (NF)** | | | |
| Type 1 | *NF1* | Astrocytoma, optic glioma, neurofibroma, leukemia | **Children**: evaluation for neurodevelopmental disorders<br>Annual physical exam including evaluation of growth, blood pressure, skin examination, bone examination, neurological examination, and vision screening<br>*(Expert opinion)* |
| Type 2 | *NF2* | Vestibular schwannoma, meningioma, ependymoma, astrocytoma | Annual physical exam including audiology assessment<br>Age 10: annual brain MRI, spinal MRI every 2-3 yr<br>*(Expert opinion)* |

# Other Single Gene Disorders

## CYSTIC FIBROSIS

- autosomal recessive disease caused by mutation of the CFTR gene which predominantly affects the lungs, but also the gastrointestinal tract
- see Respirology, R12 and Pediatrics, P82

## SICKLE CELL DISEASE

- autosomal recessive disease caused by mutation of the HBB gene resulting in the production of an abnormal version of beta-globin and subsequently distorted red blood cells
- see Hematology, H20

## DUCHENNE MUSCULAR DYSTROPHY

### Epidemiology

- 1:4000 males

### Etiology

- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) → muscle fibre fragility → fibre breakdown → necrosis and degeneration

### Clinical Feature

- proximal muscle weakness by age 3, positive Gower's sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

**Gower's Sign**
Child uses hands to "climb up" the legs to move from a sitting to a standing position

### Diagnosis

- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, EMG

### Management

- supportive (e.g. physiotherapy, wheelchairs, braces); prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

### Complications

- patient usually wheelchair-bound by age 12
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or congestive heart failure in second-third decade

# Metabolic Diseases

- individually rare but collectively occur in 1:1500 births
- inherited disorders of metabolism; most are autosomal recessive
- infants and older children may present with failure to thrive or developmental delay
- organelle disorders can present with dysmorphism
- universal newborn screening in Ontario includes some treatable metabolic disorders

Metabolic disease must be ruled out in any newborn who becomes acutely ill after a period of normal behaviour and development, or with a family history of early infant death even if the newborn screen is negative

**Table 7. Metabolic Disorders**

| | Organic and Amino Acid Disorders | Carbohydrate Disorders | Fatty Acid Disorders | Organelle Disorders |
|---|---|---|---|---|
| **Examples of Conditions** | PKU<br>Tyrosinemia<br>Homocystinuria<br>MSUD<br>Alkaptonuria<br>Urea cycle defects | Galactosemia<br>Glycogen storage diseases: von Gierke's, Pompe's, Cori's, Andersen, McArdle | MCAD deficiency<br>VLCAD deficiency<br>LCHAD deficiency | Congenital disorders of glycosylation<br>Lysosomal storage diseases: Hunter's, Hurler's, Niemann-Pick, Tay-Sachs, Gaucher, Fabry, Krabbe<br>Peroxisomal defects: Zellweger syndrome, X linked adrenoleukodystropnhy |
| **Clinical Manifestations** | Coma, Irritability, lethargy, poor feeding<br>Seizures<br>Intellectual disability<br>Vomiting and acidosis after feeding initiation<br>Sweet-smelling urine (MSUD) | Hypoglycemia, Hepatomegaly, liver failure, cardiomyopathy<br>Growth retardation, failure to thrive | Lethargy, poor feeding<br>Seizures, coma<br>Symptoms triggered by fasting<br>Liver dysfunction<br>Sudden infant death | Progressive neurological problems<br>Developmental regression<br>Chronic encephalopathy<br>Developmental delay<br>Bone crises (Gaucher)<br>Deafness, blindness |
| **Laboratory Findings** | Hyperammonemia with normal anion gap (urea cycle defects), hyperammonemia with high anion gap (organic acidemia) | Elevated liver enzymes (Galactosemia)<br>Hypoglycemia, lactic acidosis, hyperlipidemia (GSD) | Hypoketotic hypoglycemia<br>Elevated free fatty acids<br>Elevated creatine phosphokinase | Elevated urine oligosaccharides, (oligosaccharidoses) and glycosaminoglycans (mucopolysaccharidoses), abnormal transferrin isoelectric focusing (congenital disorders of glycosylation), abnormal very long chain fatty acids (peroxisomal defects) |
| **Physical Exam** | Hypotonia/hypertonia<br>Microcephaly, musty odour, eczema, hypopigmentation (PKU)<br>Dark urine, pigmented sclerae, arthralgias (alkaptonuria)<br>Lens subluxation, marfanoid appearance (homocystinuria) | Infantile cataracts (galactosemia)<br>Hepatomegaly<br>Muscle weakness/ cramping | Hepatomegaly<br>Hypotonia | Dysmorphic facial features<br>Macrocephaly (Lysosomal storage diseases)<br>Hepatosplenomegaly (Niemann-Pick type A/B/C, not Tay-Sachs)<br>Cherry-red spot on macula (Niemann-Pick type A/B, Tay-Sachs, Gaucher)<br>Corneal clouding (Hurler)<br>Infantile cataract (Fabry)<br>Peripheral neuropathy (Fabry, Krabbe)<br>Spasticity |

## Initial Investigations for a Child with Acute Problems thought to be Due to an Inborn Error of Metabolism

- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, ABGs (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)
- lactate, ammonium (hyperammonemia with urea cycle defects or organic acidemias), plasma $Ca^{2+}$ and $Mg^{2+}$, plasma amino acid screen
- routine urinalysis: ketonuria must be investigated, urinary organic acids
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, cerebrospinal fluid glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)

## Treatment

- varies according to inborn error of metabolism but includes dietary restrictions, enzyme replacement etc.
- in the presentation of acute decompensation potentially caused by an inborn error of metabolism, discontinue feeding to prevent further build up of toxic metabolites

**Table 8. Presentation and Management of Select Metabolic Disorders**

| | Phenylketonuria | Galactosemia | Maple Syrup Urine Disease | Glycogen Storage Disease Type 1 (Von Gierke Disease) |
|---|---|---|---|---|
| **Epidemiology** | 1:10,000; autosomal recessive disease (mutations in PAH) | 1:60,000; autosomal recessive disease | 1:185,000; autosomal recessive disease (mutations in BCKDHA, BCKDHB, and DBT genes), 1:25,000 Ashkenazi Jewish, 1:400 Mennonites | 1:100,000; autosomal recessive disease, 1:20,000 in Ashkenazi Jewish |
| **Etiology** | Deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build-up of phenylalanine and its toxic metabolites<br>Mothers who have PKU may have infants with multiple congenital abnormalities | Most commonly due to deficiency of galactose-1-phosphate uridyltransferase leading to an inability to process lactose/galactose | Reduction or elimination of protein complex needed for amino acid leucine, isoleucine, and valine breakdown, leading to toxic build-up | Mutations in G6PC (cause of GSD1a) and SLC37A4 (cause of GSD1b) prevent effective conversion of glucose-6-phosphate to glucose. Glucose-6-phosphate is converted to glycogen and fat which subsequently accumulates in cells, especially in the liver and kidneys |
| **Clinical Feature** | Baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors and mental retardation<br>Hypopigmentation due to low tyrosine levels (fair hair, blue eyes) | Signs of liver and renal failure, jaundice, failure to thrive, and cataracts with ingestion of lactose/galactose<br><br>Complications:<br>Increased risk of sepsis, especially *E. coli*<br>If the diagnosis is not made at birth, liver and brain damage may become irreversible | Feeding intolerance, failure to thrive, vomiting, lethargy, and maple syrup odour in urine and cerumen<br><br>May progress to irreversible mental retardation, hyperactivity, severe failure to thrive, seizures, coma, cerebral edema, and death if inadequately treated | Typically presents between 3-6 mo of age with hepatomegaly, hypoglycemia, poor fasting tolerance, growth failure and "doll-like" facies (full cheeks with thin extremities)<br><br>Complications:<br>Lactic acidosis, hyperuricemia, hyperlipidemia, delayed puberty, renal disease, hypoglycemic seizures, hepatic adenomas, ostoeporosis |
| **Diagnosis and Management** | PKU screening at birth<br>Dietary restriction of phenylalanine starting within the first 10 d of life; especially important during pregnancy to maintain normal phenylalanine levels to prevent maternal PKU effects on fetus<br>Large neutral amino acid (tyrosine) replacement, BH4 enzyme treatment, phenylalanine lyase treatment are other options | Screened for in many newborn screening programs<br>Elimination of galactose from the diet (e.g. dairy, breast milk)<br>Most infants are fed a soy-based diet | MSUD is screened in most newborn screening programs.<br>Serum amino acid evaluation (leucine, isoleucine, alloleucine, valine) and urine organic acid analysis<br>Protein-restricted, high-carbohydrate diet to limit branched amino acid intake<br>A trial of thiamine therapy in addition may be recommended for some infants | Evaluate hypoglycemia, lactic acidemia, hypertriglyceridemia and hepatomegaly<br><br>Treat with nutrition therapy (small frequent feedings, avoid fructose/sucrose/galactose), continuous overnight feedings, raw cornstarch (for slow, sustained glucose release), vitamin supplementation, frequent blood glucose monitoring |

# Imaging Modalities

## X-Ray Imaging

- x-rays are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (a process known as "attenuation") and/or scattered
- the density of a structure determines its ability to attenuate or "weaken" the x-ray beam
  - air < fat < water < bone < metal
- structures that have high attenuation (e.g. bone) appear white on the resulting images

### Plain Films

- x-rays pass through the patient and interact with a detection device (film) to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available, portable, reproducible, fast, easily read
- disadvantages: radiation exposure (minimal), generally poor at distinguishing soft tissues

### Fluoroscopy

- continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image, black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear bright
- advantages: real-time visualization of structures
- disadvantages: increased radiation dose; however, the use of pulsed fluoroscopy reduces fluoroscopy time by 76% and radiation dose by 64% as compared with continuous fluoroscopy

### Computed Tomography

- x-ray beam opposite a detector moves in a continuous 360° arc as patient is advanced through the scanner
  - anatomical structures are then reconstructed
- attenuation is quantified in Hounsfield units:
  - windowing and leveling: adjusting the "window width" (range of Hounsfield units displayed) and "window level" (midpoint value of the window width) to maximally visualize certain anatomical structures (e.g. CT chest can be viewed using "lung", "soft tissue", and "bone" settings)
- contraindications: pregnancy (relative), adverse reactions to contrast agents (e.g. allergy, renal failure)
- advantages: delineates soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, spiral/helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA non invasive compared to conventional angiography
- disadvantages: high radiation exposure, soft tissue characterization is not as good in comparison with MRI, IV contrast injection, anxiety of patient when going through scanner, higher cost, less available than plain film, typically requires expertise/radiologist interpretation

**Typical Effective Doses from Diagnostic Medical Exposures (in adults)***

| Diagnostic Procedure Type | Equivalent Number of Chest X-Rays | Approximate Equivalent Period of Natural Background Radiation** (~3 mSv/yr) |
|---|---|---|
| **X-Ray** | | |
| Skull | 5 | 12 d |
| Cervical spine | 10 | 3 wk |
| Thoracic spine | 50 | 4 mo |
| Lumbar spine | 75 | 6 mo |
| Chest (single PA film) | 1 | 2 d |
| Shoulder | 0.5 | 1 d |
| Mammography | 20 | 7 wk |
| Abdomen | 35 | 3 mo |
| Hip | 35 | 3 mo |
| Pelvis | 30 | 10 wk |
| Knee | 0.25 | <1 d |
| IVU | 150 | 1 yr |
| Dual-energy x-ray absorptiometry (without/with CT) | 0.5/2 | <1 d/4 d |
| Upper GI series | 300 | 2 yr |
| Small bowel series | 250 | 20 mo |
| Barium enema | 400 | 2.7 yr |
| **CT** | | |
| Head | 100 | 8 mo |
| Neck | 150 | 1 yr |
| Spine | 300 | 2 yr |
| Chest | 350 | 2.3 yr |
| Chest (pulmonary embolism) | 750 | 5 yr |
| Coronary angiography | 800 | 5.3 yr |
| Abdomen | 400 | 2.7 yr |
| Pelvis | 300 | 2 yr |
| **Radionuclide** | | |
| Brain (18FDG) | 705 | 4.7 yr |
| Bone ($^{99m}$Tc) | 315 | 2.1 yr |
| Thyroid ($^{99m}$Tc) | 240 | 1.6 yr |
| Thyroid (123I) | 95 | 8 mo |
| Cardiac rest-stress test ($^{99m}$Tc 1-d) | 470 | 3 yr |
| ($^{99m}$Tc 2-d) | 640 | 4 yr |
| Lung ventilation (133Xe) | 25 | 2 mo |
| Lung perfusion ($^{99m}$Tc) | 100 | 8 mo |
| Renal ($^{99m}$Tc) | 90-165 | 7-13 mo |
| Liver-spleen ($^{99m}$Tc) | 105 | 8.4 yr |
| Biliary tract ($^{99m}$Tc) | 155 | 1 yr |

# Ultrasound

- high-frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or "echo") occurs when the sound waves reflect off tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves not reflected back but pass through)
- a gel is used on the skin surface for impendence matching between the skin and transducer
- higher U/S frequencies result in greater resolution, however, deeper structures are more difficult to visualize due to weaker penetration
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. air) or absorbs (e.g. bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- Duplex scan: grey-scale imaging that utilizes the Doppler effect (sound reflecting off a moving target) to visualize the velocity of blood moving past the transducer
- Colour Doppler: assigns a colour based on the direction of blood flow (i.e. red = toward transducer, blue = away)
- advantages: relatively low cost, non-invasive, no radiation, portable, real-time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), differentiates cystic vs. solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation, low field-of-view

**Attenuation**
Bone (= bright) > grey matter > white matter ("fatty" myelin) > CSF > air (= dark)

# Magnetic Resonance Imaging

- imaging technique that does not use ionizing radiation and can produce images in virtually any plane
- patient is placed in a magnetic field generated by electric current; protons. typically from water molecules, align themselves along the plane of magnetization due to their intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on and deflects all the protons off their aligned axes. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by software to generate MR images
- the MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Remember that water is "**w**hite" on **T2** as "**W**orld **W**ar **II**"

**Methods to Reduce the Risk of Contrast-Induced Nephropathy**
- Optimal: 0.9% NaCl at 1 ml/kg/h for 12 h pre-procedure and 12 h post-contrast administration
- For same-day procedure: 0.9% NaCl or $NaHCO_3$ at 3 ml/kg/h for 1-3 h pre-procedure and for 6 h post-contrast administration

**Table 1. Differences Between Diffusion, T1- and T2-Weighted MR Imaging**

| Imaging Techniques | Contrast Enhancements | Main Application | Advantages |
|---|---|---|---|
| **Diffusion-Weighted Imaging** | Contrast dependent on the molecular motion of water<br>Decreased diffusion is hyperintense (bright), whereas increased diffusion is hypointense (dark) | Neuroradiology | Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies<br>Acute infarction and abscess collections appear hyperintense due to restricted diffusion |
| **T1-Weighted** | Fluid is hypointense (dark) and fat is hyperintense (bright) | Body soft tissues | Often considered an anatomic scan since they provide a reference for functional imaging |
| **T2-Weighted** | Fluid is hyperintense (bright) and fat is hypointense (dark) | Body soft tissues | Often considered a pathologic scan since they will highlight edematous areas associated with certain pathologies |

# Positron Emission Tomography Scans

- nuclear tracers are employed to prodce images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotopes, such as 18F, are chemically incorporated into a metabolically active molecule (e.g. glucose). These are then injected into the patient, where they travel to and accumulate in the tissues of interest. As the radioactive substance decays, γ rays are produced, and are detected by the PET scanner
- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic); in oncology, allows for diagnosis, staging, and restaging; has predictive and prognostic value; can evaluate cardiac viability
- disadvantages: cost, ionizing radiation, availability

**Contraindications to IV Contrast**

**MADD Failure**
**M**ultiple myeloma
**A**dverse reaction previously
**DM**
**D**ehydration
**F**ailure (renal, severe heart)

# Contrast Enhancement

**Table 2. Contrast Agents**

| Imaging Modality | Types | Advantages | Disadvantages | Contraindications |
|---|---|---|---|---|
| **X-Ray/CT** | 1. Barium (oral or rectal) | Radio-opaque substance that helps to delineate intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects | | Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation |
| | 2. Iodine (IV injection) | Delineates intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ | | Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure and dehydration eGFR <60 may require preventative measures and follow-up |
| **MRI** | Gadolinium-Chelates (IV injection) | Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; gadolinium has some effect on T2-relaxation time; highlights highly vascular structures (e.g. tumours) | Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease | Previous adverse reaction to contrast or end-stage renal disease (relative contraindication) |
| **U/S** | Microbubbles (IV injection) | Since gas is highly echogenic, the microbubbles allow for echo-enhancement of a tissue | | Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions |

# Chest Imaging

## Chest X-Ray

### Standard Views

- PA: anterior chest against film plate to minimize magnification of the heart size
- lateral: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
  - helps localize lesions when combined with PA view
- AP: for bedridden patients (generally a lower quality film than PA because of enlarged cardiac silhouette)
- lateral decubitus: to assess for pleural effusion and pneumothorax in bedridden patients; however, point of care ultrasound (POCUS) can also be utilized for both of these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

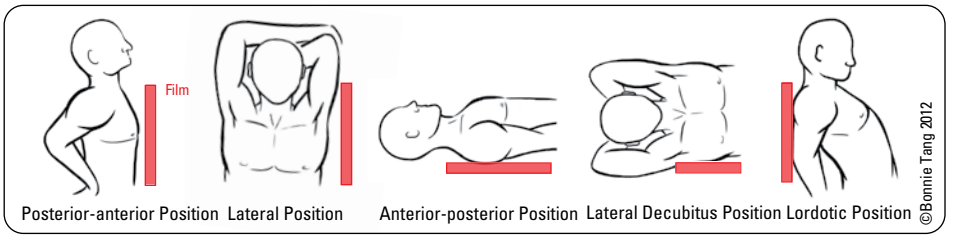

**Figure 1. CXR views**

### Approach to CXR

### Basics

- ID: patient name, MRN, sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)

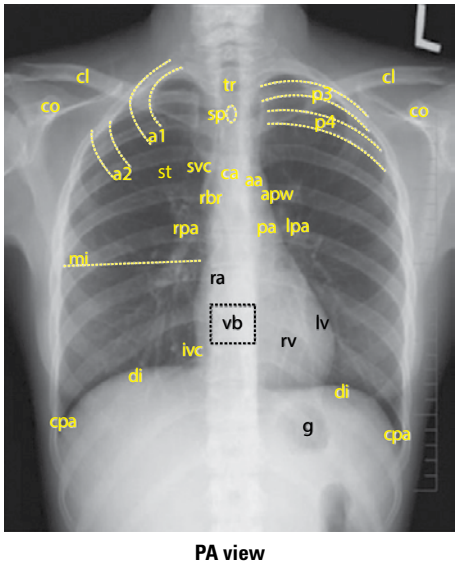
## Analysis

- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see *Abdominal Imaging*, MI10)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowel
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: parenchyma, pleura, diaphragm
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
- please refer to Toronto Notes website for supplementary material on how to approach a CXR

**Chest X-Ray Interpretation**

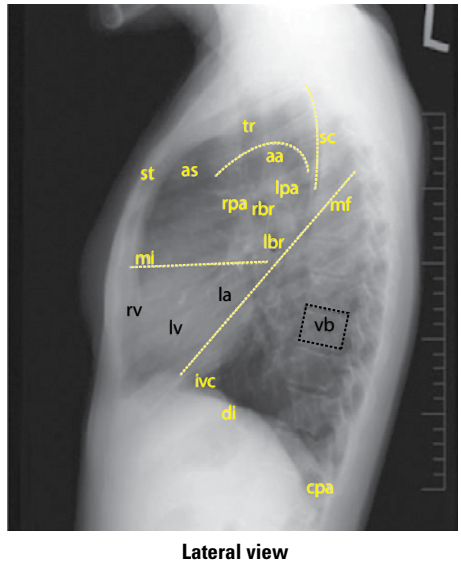
**Basics ABCDEF**
**A**P, **P**A or other view
**B**ody position/rotation
**C**onfirm name
**D**ate
**E**xposure/quality
**F**ilms for comparison

**Analysis ABCDEF**
**A**irways and hilar **A**denopathy
**B**ones and **B**reast shadows
**C**ardiac silhouette and **C**ostophrenic angle
**D**iaphragm and **D**igestive tract
**E**dges of pleura
**F**ields (lung fields)



## Anatomy

## Localizing Lesions for Parenchymal Lung Disease



- silhouette sign: when two objects of the same radiolucency contact each other, they become indistinguishable on imaging and result in the loss of normal interfaces (i.e. the silhouette expected at an anatomical border disappears). The silhouette sign can be used to identify lung pathology (consolidation, atelectasis, mass) and localize disease to specific lung segments. This sign is not only used in the chest, but can also be an aid to interpreting imaging studies throughout the body
- spine sign: on lateral films, vertebral bodies should appear progressively radiolucent (dark) as one moves down the thoracic vertebral column; if they appear more radio-opaque, it is an indication of pathology (e.g. consolidation in overlying lower lobe)
- air bronchogram: branching pattern of air-filled bronchi on a background of opacification/fluid-filled airspaces

**Table 3. Localization Using the Silhouette Sign**

| Interface Lost | Location of Lung Pathology |
|---|---|
| SVC/right superior mediastinum | RUL |
| Right heart border | RML |
| Right hemidiaphragm | RLL |
| Aortic knob/left superior mediastinum | LUL |
| Left heart border | Lingula |
| Left hemidiaphragm | LLL |

# Computed Tomography Chest

## Approach to CT Chest

- soft tissue window
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary
- bone window
  - vertebrae, sternum, ribs: fractures, lytic lesions, sclerosis
- lung window
  - trachea: patency, secretions
  - bronchi: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma:, nodules, fibrosis,interstitial changes,consolidation
  - pleural space: effusions
- please refer to Toronto Notes website for supplementary material on how to approach a CT chest

**Table 4. Types of CT Chest**

| | Advantage | Disadvantage | Contrast | Indication |
|---|---|---|---|---|
| **Standard** | Scans full lung very quickly (<1 min)<br>± high resolution reconstructions | Radiation | ± | CXR abnormality<br>Pleural and mediastinal abnormality<br>Lung cancer staging<br>Cancer follow-up<br>Empyema vs. abscess |
| **Low Dose** | 1/5th the radiation | Decreased detail | No | Lung cancer screening<br>Follow-up infections, lung transplant, metastases |
| **CTA** | Iodinated contrast highlights vasculature (Scan timed for maximum opacification of vessel being studied) | Contrast can cause severe allergic reaction and is nephrotoxic | Yes | PE<br>Aortic aneurysms<br>Aortic dissection |

# Lung Abnormalities

## Atelectasis

- pathogenesis: collapse of lung tissue due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
- post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
  - compressive
  - tumour, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
- hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space
- pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax) to rule out a bronchogenic carcinoma

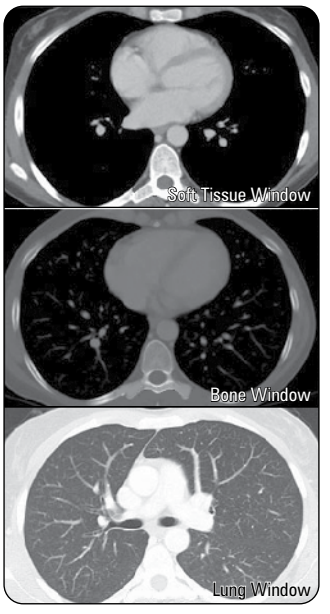

**Figure 4. CT thorax windows**

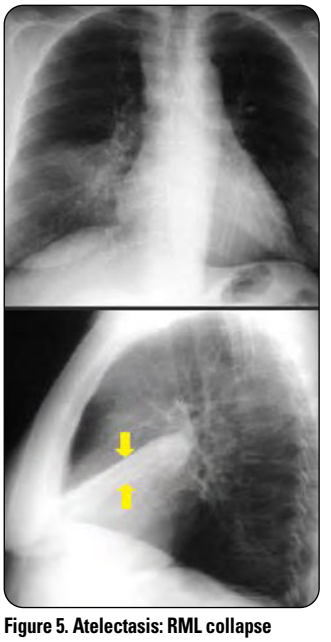

**Figure 5. Atelectasis: RML collapse**

**DDx of Airspace Disease**

- Pus (e.g. infections such as pneumonia)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)

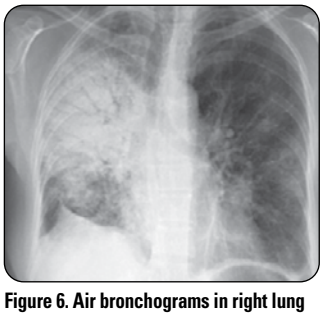

**Figure 6. Air bronchograms in right lung**

## Consolidation

- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumour in alveoli
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign
- differential diagnosis
  - fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, COP (cryptogenic organizing pneumonia), allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: bronchoalveolar carcinoma, lymphoma
- management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

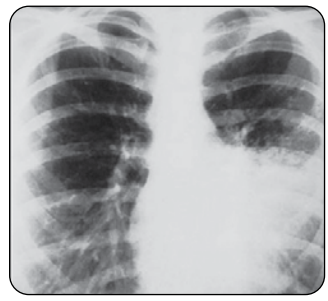

**Figure 7. Consolidation: bacterial pneumonia**

## Interstitial Disease

- pathogenesis: pathological process involving the interlobular connective tissue (i.e. "scaffolding of the lung")
- findings
  - septal thickening: fine lines caused by thickened connective tissue septae (most commonly due to pulmonary edema or lymphangitis carcinomatosis)
  - these manifest on Chest X-ray as:
    - Kerley A: long thin lines in upper lobes
    - Kerley B: short horizontal lines extending from lateral lung margin
    - Kerley C: diffuse linear pattern throughout lung
  - nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
    - seen in malignancy, pneumoconiosis, and granulomatous disease (e.g. sarcoidosis, miliary TB)
  - reticular: fine curvilinear opacities
    - seen in interstitial lung diseases (pulmonary fibrosis)
    - watch for pneumothorax as a complication
  - reticulonodular: combination of reticular and nodular patterns
  - may also see signs of airspace disease (atelectasis, consolidation)
- differential diagnosis
  - occupational/environmental exposure
    - inorganic: asbestosis, coal miner's pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    - organic: hypersensitivity pneumonitis, bird fancier's lung, farmer's lung (mouldy hay), and other organic dust
  - autoimmune: connective tissue diseases. (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
  - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), heroin, cocaine, methadone
  - infections: non-tuberculous mycobacteria, certain fungal infections
  - idiopathic: hypersensitivity pneumonitis, IPF
  - for Causes of *Interstitial Lung Disease* Classified by Distribution, see Respirology, R13
  - management: high-resolution CT thorax and ± biopsy

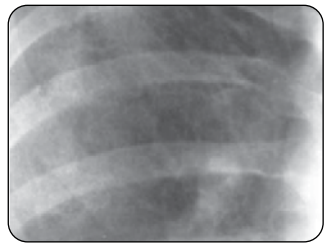

**Figure 8. Interstitial disease: fine reticular pattern**

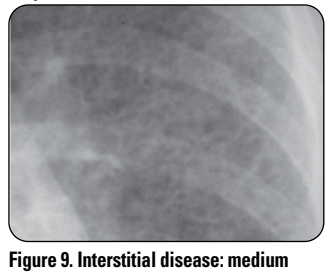

**Figure 9. Interstitial disease: medium reticular pattern**

## Pulmonary Nodule

- findings
  - round opacity ± silhouette sign
  - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- differential diagnosis
  - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  - solitary nodule
- tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
- inflammation: histoplasmoma, tuberculoma, coccidioidomycosis
- vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
  - multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, GPA)
- management: clinical information and CT appearance determine level of suspicion of malignancy
  - if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/transthoracic biopsy) is indicated
  - if low probability of malignancy, follow-up imaging as per Fleischner guidelines 2017

**DDx of Interstitial Lung Disease**

**FASSTEN (upper lung disease)**
**F**armer's lung (hypersensitivity pneumonitis)
**A**nkylosing spondylitis
**S**arcoidosis
**S**ilicosis

**D**evelopmental cysts (sequestration)
**H**istiocytosis
**O**ncological
**L**ymphangioleiomyomatosis
**E**nvironmental, occupational
**S**arcoidosis

**Table 5. Characteristics of Benign and Malignant Pulmonary Nodules**

| | Malignant | Benign |
|---|---|---|
| **Margin** | Ill-defined/spiculated ("corona radiata") | Well-defined |
| **Contour** | Lobulated | Smooth |
| **Calcification** | Eccentric or stippled | Diffuse, central, popcorn, concentric |
| **Doubling Time** | 20-460 d | <20 d or >460 d |
| **Other Features** | Cavitation, collapse, adenopathy, pleural effusion, lytic bone lesions, smoking history | |
| **Size** | >3 cm | <3 cm |
| **Cavitation** | Yes, especially with wall thickness >15 mm, eccentric cavity, and shaggy internal margins | No |
| **Satellite Lesions** | No | Yes |

**Figure 10. Pulmonary nodule: bronchogenic carcinoma**

# Pulmonary Vascular Abnormalities

## Pulmonary Edema

- pathogenesis: fluid accumulation in the airspaces of the lungs
- findings
  - vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
  - fluid initially collects in interstitium
- loss of definition of pulmonary vasculature
- peribronchial cuffing
- Kerley B lines
- reticulonodular pattern
- thickening of interlobar fissures
  - as pulmonary edema progresses, fluid collects in alveoli and causes diffuse airspace disease, often in a "bat wing" or "butterfly" pattern in perihilar regions (outermost lung fields tend to be spared)
- differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

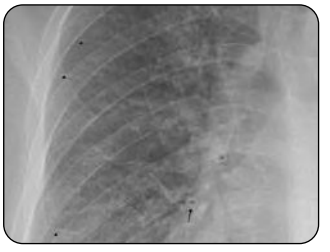

**Figure 11. Peribronchial cuffing**

## Pulmonary Embolism

- pathogenesis: arterial blockage in the pulmonary arteries due to emboli from pelvic or leg veins, rarely from PICC lines, ports, air, fat, or amniotic fluid
- findings
  - generally not possible to definitively diagnose on plain film. Diagnosis made by CT pulmonary angiogram or Ventilation/perfusion scinticraphy. (VQ scan)
  - CXR: Westermark sign (localized pulmonary oligemia), Hampton's hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
  - definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries
  - VQ scan: Can be used in patients with impaired renal function or in pregnancy

# Pleural Abnormalities

## Pleural Effusion

**Table 6. Sensitivity of Plain Film Views for Pleural Effusion**

| X-Ray Projection | Minimum Volume to Visualize |
|---|---|
| **Lateral decubitus** | 25 mL: most sensitive |
| **Upright lateral** | 50 mL: meniscus seen in the posterior costophrenic sulcus |
| **PA** | 200 mL |
| **Supine** | Diffuse haziness |

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis; POCUS is now standard of care in acute situations

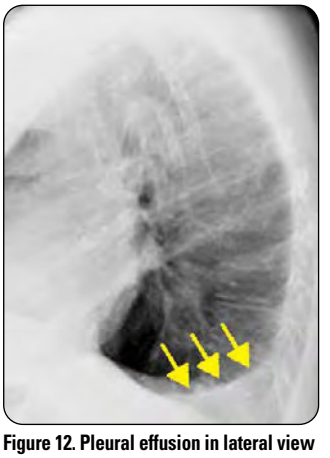

**Figure 12. Pleural effusion in lateral view**

### Pneumothorax

- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- findings
  - upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air. Occasional tracheal deviation to side of pneumothorax, except in tension pneumothorax
  - more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  - more difficult to detect on supine film; look for the "deep (costophrenic) sulcus" sign, "double diaphragm" sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  - mediastinal shift may occur in tension pneumothorax
- differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, central venous catheter insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
- management: needle decompression in 2nd ICS midclavicular line or chest tube insertion in 5th ICS anterior axillary line, repeat CXR to ensure resolution

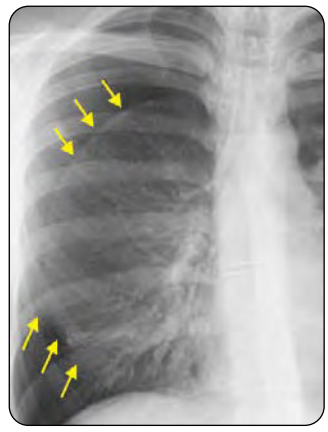

**Figure 13. Pneumothorax**

### Asbestos

- asbestos exposure may cause various pleural abnormalities including benign plaques (most common; these may calcify), diffuse pleural fibrosis, effusion, and malignant mesothelioma

## Mediastinal Abnormalities

### Mediastinal Mass

- the mediastinum is divided into four compartments; this provides an approach to the differential diagnosis of a mediastinal mass
- anterior border formed by the sternum and posterior border by the heart and great vessels
  - 4 Ts: thyroid, thymic neoplasm, teratoma, terrible lymphoma
  - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
- middle border (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
  - esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
- posterior border (posterior to the middle line described above)
- neurogenic tumour (e.g. neurofibroma, schwannoma), neurenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
- superior boundaries (superiorly by thoracic inlet, inferiorly by plane of the sternal angle, anteriorly by manubrium, posteriorly by T1-T4, laterally by pleura)
- in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, or hematoma

**Elevated Hemidiaphragm Suggests**
**PAL DIP**
**P**regnancy
**A**telectasis
**L**ung resection
**D**iaphragmatic paralysis
**I**ntra-abdominal process
**P**neumonectomy
**P**leural effusion also may result in apparent elevation

**Depressed Hemidiaphragm Suggests**
**TALC**
**T**umour
**A**sthma
**L**arge pleural effusion
**C**OPD

**DDx Anterior Mediastinal Mass**
**4 Ts**
**T**hyroid
**T**hymic neoplasm
**T**eratoma
**T**errible lymphoma

### Enlarged Cardiac Silhouette

- heart borders
  - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
- cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
  - using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
  - differential of ratio >0.5
    - cardiomegaly (myocardial dilatation or hypertrophy)
    - pericardial effusion
    - poor inspiratory effort/low lung volumes
    - pectus excavatum
- ratio <0.5 does not exclude enlargement
- pericardial effusion: globular heart with loss of indentations on left mediastinal border
- RA enlargement: increase in curvature of right heart border and enlargement of SVC
- LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and "double" heart border >7 cm, splayed carina (late sign)
- RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
- LV enlargement: rounding of the cardiac apex; displacement of left cardiac boarder leftward, inferiorly, and posteriorly

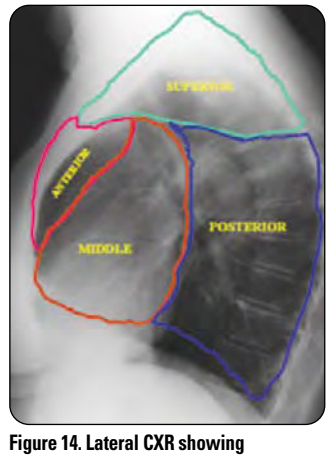

**Figure 14. Lateral CXR showing four mediastinal compartments**

# Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

### Central Venous Catheter
- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- Ideally located at the SVC/Atrial junction to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- course should parallel that of the SVC; if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

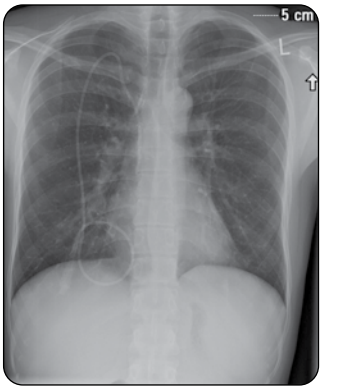

**Figure 15. CXR showing well-positioned central venous catheter**

### Endotracheal Tube
- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 2-4 cm above tracheal carina (avoids bronchus intubation and vocal cord irritation)
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture; ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

### Nasogastric Tube
- tip and side port should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), pneumothorax

### Swan-Ganz Catheter
- to monitor pulmonary capillary wedge pressure and estimate diastolic filling of left heart
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture/aneurysm
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

### Chest Tube
- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: bleeding, infection, lung laceration

# Abdominal Imaging

## Abdominal X-Ray

**3 Views of AXR**
- Erect/Upright
- Supine
- Left lateral decubitus

### Indications
- acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
- chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
- not useful in: GI bleeds, chronic anemia, vague GI symptoms

### Anatomy
- abdomen divided into 2 cavities:
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

**Table 7. Differentiating Small and Large Bowel**

| Property | Small Bowel | Large Bowel |
|---|---|---|
| **Mucosal Folds** | Uninterrupted valvulae conniventes (or plicae circularis) | Interrupted haustra extend only partway across lumen |
| **Location** | Central | Peripheral (picture frame) |
| **Maximum Diameter** | 3 cm | 6 cm (9 cm at cecum) |
| **Maximum Fold Thickness** | 3 mm | 5 mm |
| **Other** | Rarely contains solid fecal material | Commonly contains solid fecal material |

**3-6-9 Rule of Dilation**
Small bowel (>3 cm)
Large bowel (>6 cm)
Cecum (>9 cm)

# Approach to Abdominal X-Ray

- mnemonic: "Free ABDO"
- "Free": free air and fluid
  - free fluid
    - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
    - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph, and therefore, cannot be differentiated
    - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon), penetrating trauma, or recent (<7 d) surgery
- "A": air in the bowel (can be normal, ileus, or obstruction)
  - volvulus – twisting of the bowel upon itself; from most to least common:
    - **sigmoid**: "coffee bean" sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal dilation
    - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
    - gastric: rare
    - transverse colon: rare (usually young individuals)
    - small bowel: "corkscrew sign" (rarely diagnosed on plain films, seen best on CT)
  - toxic megacolon
    - manifestation of fulminant colitis
    - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps), loss of normal haustral pattern
- "B": bowel wall thickening
  - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall ("thumb-printing"), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
  - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
- "D": densities
  - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
  - abnormal calcifications: approach by location
    - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
    - RLQ: ureteral stone, appendicolith, gallstone ileus
    - LUQ: renal stone, adrenal calcification, tail of pancreas
    - LLQ: ureteral stone
    - central: aorta/aortic aneurysm, pancreas, lymph nodes
    - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
- "O": organs
  - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
  - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

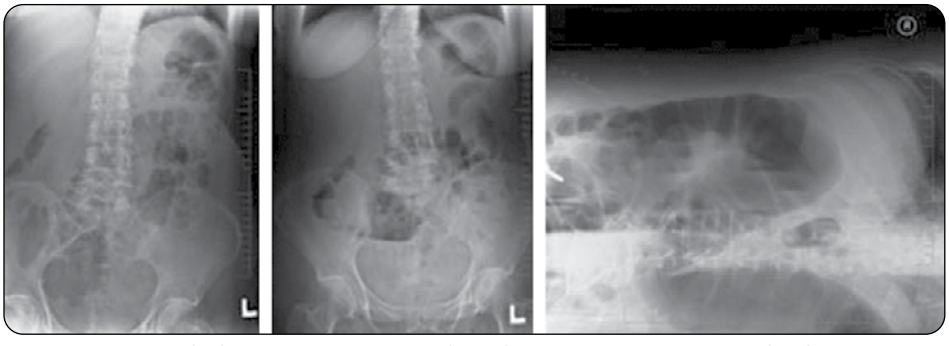

**Figure 16. Normal AXRs: (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR**

**Biliary vs. Portal Venous Air**
"Go with the flow": air follows the flow of bile or portal venous blood
Biliary air is most prominent centrally over the liver
Portal venous air is most prominent peripherally

**Table 8. Abnormal Air on Abdominal X-Ray**

| Air | Appearance | Common Etiologies |
|---|---|---|
| **Extraluminal**<br>Intraperitoneal (pneumoperitoneum) | Upright film: air under diaphragm<br>Left lateral decubitus film: air between liver and abdominal wall<br>Supine film: gas outlines of structures not normally seen:<br>Inner and outer bowel wall (Rigler's sign)<br>Falciform ligament<br>Peritoneal cavity ("football" sign) | Perforated viscus<br>Post-operative (up to 10 d to be resorbed) |
| Retroperitoneal | Gas outlining retroperitoneal structures allowing increased visualization:<br>Psoas shadows<br>Renal shadows | Perforation of retroperitoneal segments of bowel: duodenal ulcer, post-colonoscopy |
| **Intramural** (pneumatosis intestinalis) | Lucent air streaks in bowel wall, 2 types:<br>1. Linear<br>2. Rounded (cystoides type) | 1. Linear: ischemia, necrotizing enterocolitis<br>2. Rounded/cystoides (generally benign): primary (idiopathic), secondary to COPD |
| **Intraluminal** | Dilated loops of bowel, air-fluid levels | Adynamic (paralytic) ileus, mechanical bowel obstruction |
| **Loculated** | Mottled, localized in abnormal position without normal bowel features | Abscess (evaluate with CT) |
| **Biliary** | Air centrally over liver | Sphincterotomy, gallstone ileus, erosive peptic ulcer, cholangitis, emphysematous cholecystitis |
| **Portal Venous** | Air peripherally over liver in branching pattern | Bowel ischemia/infarction |

**Table 9. Adynamic Ileus vs. Mechanical Obstruction**

| Feature | Adynamic Ileus | Mechanical Obstruction |
|---|---|---|
| **Calibre of Bowel Loops** | Normal or dilated | Usually dilated |
| **Air-Fluid Levels** (erect and left lateral decubitus films only) | Same level in the same single loop | Multiple air fluid levels giving "step ladder" appearance, dynamic (indicating peristalsis present), "string of pearls" (row of small gas accumulations in the dilated valvulae conniventes) |
| **Distribution of Bowel Gas** | Air throughout GI tract is generalized or localized<br>In a localized ileus (e.g. pancreatitis, appendicitis), dilated "sentinel loop" remains in the same location on serial films, usually adjacent to the area of inflammation | Dilated bowel up to the point of obstruction (i.e. transition point)<br>No air distal to obstructed segment<br>"Hairpin" (180°) turns in bowel |

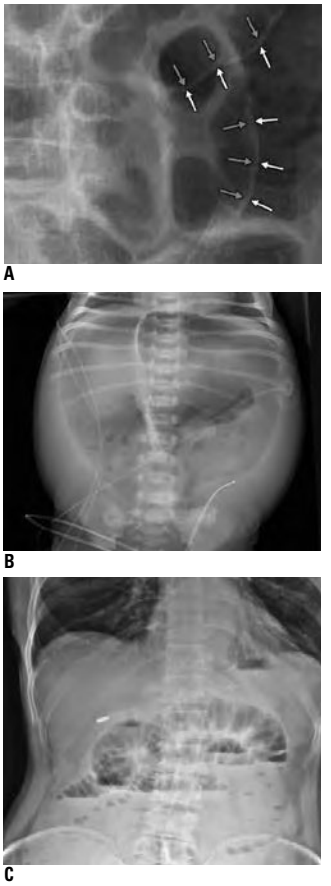

**Figure 17. (A) Rigler's sign (B) "football" sign (C) string of pearls sign**

Rigler's sign courtesy of Dr Jeremy Jones, Radiopaedia.org, rID: 8041. Prof Frank Gaillard https://radiopaedia.org/cases/8041

Football sign courtesy of Dr Maxime St-Amant, Radiopaedia.org, rID: 18597. https://radiopaedia.org/cases/18597

String of pearls courtesy of Dr Maulik S Patel, Radiopaedia.org, rID: 14006. https://radiopaedia.org/cases/14006

# Abdominal Computed Tomography

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast:
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
- portal venous phase: indicated for majority of cases
- biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
- caution: contrast allergy (may pre-medicate with steroids and antihistamine)
- contraindication: impaired renal function (based on eGFR)
  - oral contrast: barium or water-soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions

# Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ or structure individually, from top to bottom, evaluating the size and shape of each area of increased or decreased density
- evaluate the following:
  - soft tissue window
    - liver, gallbladder, spleen, and pancreas
    - adrenals, kidneys, ureters, and bladder
    - stomach, duodenum, small bowel mesentery, and colon/appendix
    - retroperitoneum (aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels)
    - peritoneal cavity for fluid or masses
    - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebrae, spinal cord, and bony pelvis

**Figure 18. Sigmoid volvulus on plain film, "coffee bean sign"**

Courtesy of Dr Henry Knipe, Radiopaedia.org, rID: 28620. https://radiopaedia.org/cases/28620

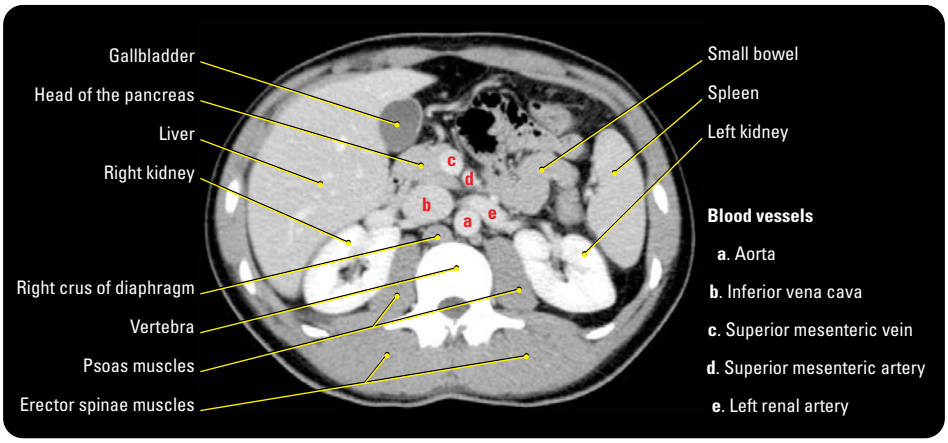

**Figure 19. Axial abdominal computed tomography**

### CT and Bowel Obstruction

- cause of bowel obstruction is rarely found on plain films; CT is the best imaging modality
- the "3,6,9" rule is a very useful guide for determining when the bowel is dilated; the maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel, and 9 cm for cecum; this can also be useful to distinguish small and large bowel, and to assess for 'impending' cecal perforation (e.g. post-untreated Ogilvie's syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

### CT Colonography (virtual colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, or staging of obstructing colonic lesions

**Colorectal Cancer: CT Colonography and Colonoscopy for Detection-Systematic Review and Meta-Analysis**
Radiology 2011;259:393-405
**Purpose**: To assess the sensitivity of computed tomography (CT) colonography and optical colonoscopy (OC) for colorectal cancer (CRC) detection.
**Methods**: Systematic review and meta-analysis of diagnostic studies evaluating CT colonography detection of CRC based on a priori eligibility criteria, in particular requiring both OC and histological confirmation of disease. Studies that also assessed true-positive and false-negative diagnoses with OC were used to calculate OC sensitivity. Sensitivity of CTC and OC for CRC was the main outcome.
**Results**: 49 studies on 11,151 patients undergoing diagnostic study for detection of CRC were included. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.
**Conclusion**: CTC is highly sensitive for the detection of CRC and may be a better modality for the initial investigation of suspected CRC, assuming reasonable specificity.

## Contrast Studies

**Table 10. Types of Contrast Studies**

| Study | Organ | Procedure Description | Assessment | Findings |
|---|---|---|---|---|
| **Cine Esophagogram** | Cervical esophagus | Contrast agent swallowed Recorded for later playback and analysis | Dysphagia, swallowing incoordination, recurrent aspiration, post-operative cleft palate repair | Aspiration, webs (partial occlusion), Zenker's diverticulum, cricopharyngeal bar, laryngeal tumour |
| **Barium Swallow** | Thoracic esophagus | Contrast agent swallowed under fluoroscopy, selective images captured | Dysphagia, rule out GERD, post-esophageal surgery | Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear |
| **Upper GI Series** | Thoracic esophagus, stomach, and duodenum | Double contrast study:<br>1. Barium to coat mucosa<br>2. Gas pills for distention<br>Patient NPO after midnight | Dyspepsia, investigate possible upper GI bleed, weight loss/ anemia, post-gastric surgery | Ulcers, neoplasms, filling defects |
| **Enterography and Enteroclysis (MRI or CT)** | Entire small bowel | Enterography: patient drinks 1-2 L of sorbitol, psyllium, or barium solution to distend small bowel<br>Enteroclysis: NJ tube used to pump barium, psyllium, or sorbitol contrast media directly into small bowel | IBD, malabsorption, weight loss/anemia, Meckel's diverticulum | Neoplasms, IBD, malabsorption, infection |

# Specific Visceral Organ Imaging

- for the management of urgent and emergent peritoneal masses, see, General Surgery, GS20

## Liver

- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumours, liver metastases, other parenchymal conditions, and is particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- elastography: measures shear wave velocity by U/S (Fibroscan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings:
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - portal HTN: increased portal vein diameter, collateral veins, splenomegaly (≥12 cm), portal vein thrombosis, recanalization of the umbilical vein
  - porto-systemic shunts: caput medusae, esophageal varices, spontaneous spleno-renal shunt
  - U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
  - CT: fatty infiltration appears hypodense
- in order to be visualized, some masses require contrast
- upon identifying a liver lesion on imaging (e.g. U/S), the follow-up imaging modality should be CT or MR. CT would be four-phase non-contrast, arterial, venous, and delayed to distinguish the common benign liver lesion hemangioma from other tumours

Normal liver appears more dense than spleen on CT. If less dense, suspect fatty infiltration

**Liver Mass DDx**

**5 Hs**
**H**CC
**H**ydatid cyst
**H**emangioma
**H**epatic adenoma
**H**yperplasia (focal nodular)

**Table 11. Imaging of Liver Masses**

| Mass | U/S | CT |
|---|---|---|
| **Benign** | | |
| **Hepatic Adenoma** | Well-defined mass with hyperechoic areas due to hemorrhage | Well-defined hypervascular lesion with enlarged central vessel becoming slightly isoattenuating in venous phase |
| **Hemangioma** | Homogeneous hyperechoic mass | Peripheral globular enhancement in arterial phase scans; central filling and persistent enhancement on delayed scans |
| **Focal Nodular Hyperplasia** | Well-defined mass, central scar seen in 50% of cases | Hypervascular mass in arterial phase and isoattenuation to liver in portal venous phase |
| **Abscess** | Ill-defined, irregular margin, hypoechoic contents | Low attenuation lesion with an irregular enhancing wall |
| **Hydatid Cyst** | Simple/multiloculated cyst | Low attenuation simple or multiloculated cyst; calcification |
| **Malignant** | | |
| **HCC** | Single/multiple masses, or diffuse infiltration | Hypervascular; enhances in arterial and washes out in venous phase with portal venous tumour thrombus |
| **Metastases** | Multiple masses of variable echotexture | Usually low attenuation on contrast-enhanced scan |

**Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease**
Arch Intern Med 1998;154:2573-2581
**Purpose**: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including ultrasonography (U/S), oral cholecystography, radionucleotide scanning with Technetium, magnetic resonance imaging (MRI) or computed tomography (CT).
**Methods**: Meta-analysis of studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease. Main outcomes were sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.
**Results**: Thirty studies were included. For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI 0.95-0.99) and specificity (0.95, 0.88-1.00) and adjusted (for verification bias) sensitivity (0.84; 0.76-0.92) and specificity (0.99; 95% CI 0.97-1.00). For evaluating acute cholecystitis, radionucleotide scanning has the best sensitivity (0.97; 0.96-0.98) and specificity (0.90; 0.86-0.95).
**Conclusion**: U/S is the test of choice for diagnosing cholelithiasis and radionucleotide scanning is the superior test for diagnosing acute cholecystitis.

## Spleen

- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

## Pancreas

- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
  - MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
  - ERCP: endoscope to inject dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval)
    - acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

## Biliary Tree

- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

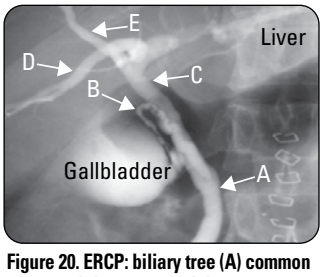

**Figure 20. ERCP: biliary tree (A) common bile duct (B) cystic duct (C) common hepatic duct (D) right hepatic duct (E) left hepatic duct**

# "itis" Imaging

## Acute Cholecystitis

- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct, or in the case of acalculous cholechystitis, due to gallbladder ischemia or cholestasis (see General Surgery, GS52)
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: most sensitive findings are presence of gallstones and positive sonographic Murphy's sign (tenderness from pressure of U/S probe over visualized gallbladder). Secondary findings include thickened gallbladder wall (>3 mm), dilated gallbladder, and pericholecystic fluid
- management: admit, NPO, IVF, analgesia, cefazolin, and early laparoscopic cholecystectomy

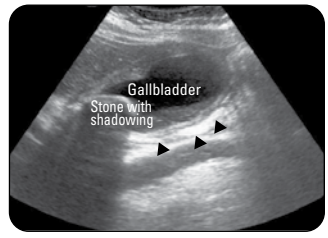

**Figure 21. Ultrasound: Longitudinal view of an inflamed Gallbladder. Arrow heads show thickened walls and pericholecystic fluid**

## Acute Appendicitis

- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see General Surgery, GS32)
- best imaging modality: U/S or CT
- findings
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: admit, NPO, IVF, analgesia, cefazolin + metronidazole, and appendectomy

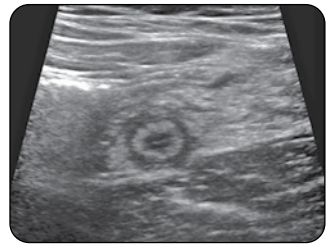

**Figure 22. Ultrasound: inflamed appendix**

## Acute Diverticulitis

- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see General Surgery, GS36)
- best imaging modality: CT, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel
- findings:
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (send abscess fluid for cytology and follow-up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

**Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents**
Ann Intern Med 2004;141:537-546
**Purpose**: To review the diagnostic accuracy of computed tomography (CT) and ultrasonography (U/S) in the diagnosis of acute appendicitis.
**Methods**: Meta-analysis of prospective studies evaluating the use of CT or U/S, followed by surgical or clinical follow-up in patients with suspected appendicitis. Patients aged ≥14 yr with a clinical suspicion of appendicitis were eligible. Sensitivity and specificity using surgery or clinical follow-up as the gold standard were the main outcomes studied.
**Results**: Twenty-two studies were included. CT (12 studies) had an overall sensitivity of 0.94 (95% CI 0.91-0.95) and a specificity of 0.95 (0.93-0.96). U/S (14 studies) had an overall sensitivity of 0.86 (0.83-0.88) and a specificity of 0.81 (0.78-0.84).
**Conclusion**: CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

## Acute Pancreatitis

- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see Gastroenterology, G46); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings:
  - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, fat stranding with indistinct fat planes, mesenteric and Gerota's fascia (renal fascia) thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
  - CT-guided needle aspiration and/or drainage of abscess when clinically indicated
  - pseudocyst may be followed by CT and drained if symptomatic

## Chronic Pancreatitis

- pathogenesis: (see Gastroenterology, G48)
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland

# Angiography of Gastrointestinal Tract

- anatomy of the arterial branches of the GI tract
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
- flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

**Angiography requires active blood loss**
1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding

# Genitourinary System and Adrenal

## Urological Imaging

### KUB (Kidney, Ureter, and Bladder X-ray)

- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones types except for uric acid and indinavir), indwelling ureteric stents/catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows better visualization of the urinary tract, but has been largely replaced by CT urography

**Imaging Modality Based on Presentation**
- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloating = Plain film/CT (if abnormal)
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = HSG, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram

### Abdominal CT

### Renal Masses

- Bosniak classification for cystic renal masses
- class I-II: benign and can be disregarded
- class IIF: should be followed
- class III-IV: suspicious for malignancy, requiring additional workup

**Table 12. Bozniak Classification for Cystic Renal Masses**

| Classes | Definition |
|---|---|
| **Simple Renal Cysts** | |
| **Class I** | Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hair thin wall |
| **Class II** | Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (<3 cm) that do not enhance with contrast<br>*Class IIF: multiple hairline-thin septa with minimal thickening, no enhancing soft tissue components, completely intrarenal non-enhancing high-attenuating renal lesions >3 cm |
| **Complex Renal Cysts** | |
| **Class III** | Thick irregular walls ± calcifications ± septated, enhancing walls or septa with contrast |
| **Renal Cell Carcinoma** | |
| **Class IV** | Same as class III + soft tissue enhancement with contrast (defined as >10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis |

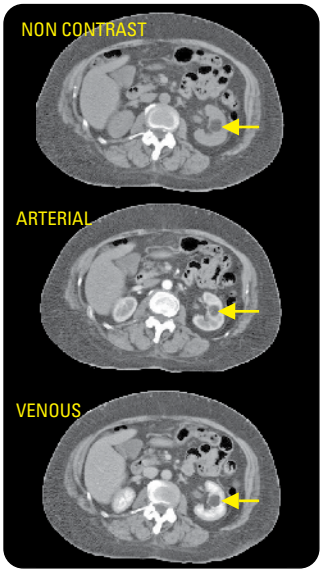

**Figure 23. Triphasic CT of an angiomyolipoma**: showing fat density with non-contrast scan, mildly enhancing with contrast

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location) and potential sequalae (infection and obstruction), and hydronephrosis prior to urological treatment
- CT urography indications: investigation of cause of hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
- renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses, especially in differentiating renal cell carcinoma from more benign masses, and pre-operative staging
  - phases: unenhanced, arterial and venous (nephrographic), excretory

### Ultrasound

- **indications**: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic masses, simple vs. complicated cysts); modality of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation to patient, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- **findings**: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

### Retrograde Pyelography
- indications: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiograph or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction or allergy to IV contrast)
- findings: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

### Voiding Cystourethrogram
- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time X-ray) to visualize bladder during voiding
- indications: males or young females with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction, suspected bladder trauma or vesicoureteral reflux
- findings: evaluation of bladder contractility and evidence of vesicoureteral reflux

### Retrograde Urethrogram
- a small Foley catheter placed into penile urethral opening, followed by instillation of contrast and radiographic imaging
- indications: used mainly to study strictures or trauma to the male urethra; first-line study if trauma with blood present at urethral meatus, scrotal hematoma present or high-riding prostate (signs of urethral injury)

### MRI
- advantages: better contrast resolution and tissue discrimination, lack of exposure to ionizing radiation, safer contrast, ability to obtain imaging directly from multiple planes (coronal, sagittal, oblique)
- indications: indicated over CT for depiction of renal masses in patients with previous nephron-sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

### Renal Nuclear Scan

**Table 13. Renal Scan Tests**

| Type of Test | Uses | Radionuclide |
|---|---|---|
| **Renogram** | Assess renal function and collecting system: evaluation of renal failure, workup of urinary tract obstruction and renovascular HTN, investigation of renal transplant | IV $^{99m}$Tc-pentetate (DTPA) or mertiatide (MAG3), and imaged at 1-3 s intervals with a gamma camera over the first 60 s to assess perfusion |
| **Morphological** | Assess renal anatomy: investigation of pyelonephritis and cortical scars | $^{99m}$Tc-DMSA<br>$^{99m}$Tc-glucoheptonate |

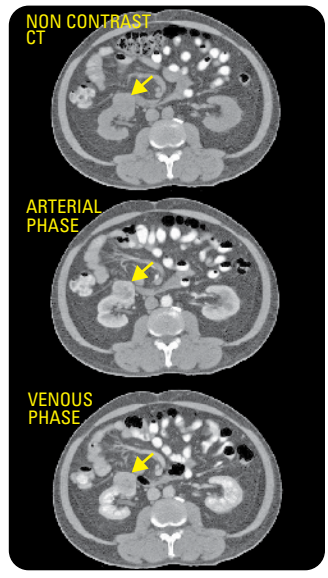

**Figure 24. Triphasic CT of a renal cell carcinoma:** showing arterial enhancing right renal lesion with venous washout (shunting)

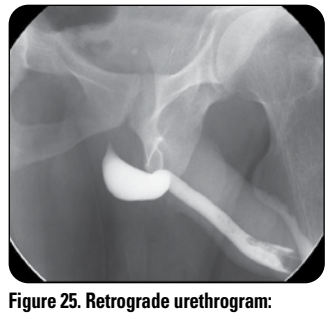

**Figure 25. Retrograde urethrogram: demonstrating stricture in the membranous urethra**

## Gynecological Imaging

### Ultrasound
- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air-containing loops of bowel
  - indications: good initial investigation for suspected pelvic pathology
- TVUS provides a panoramic pelvic view and enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves due to reduced distances
  - indications: improved assessment of ovaries, first trimester development, and ectopic pregnancy

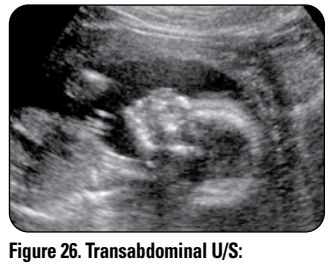

**Figure 26. Transabdominal U/S: pregnancy, 18 wk fetus**

Pregnancy should always be ruled out by β-hCG before CT of a female pelvis (or any organ system) is performed

### Hysterosalpingogram
- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- indications: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

### CT/MRI
- indications: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies and detecting recurrence

### Sonohysterogram
- transcervical saline introduction into uterine cavity to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

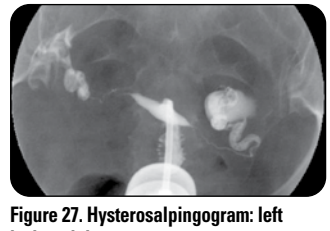

**Figure 27. Hysterosalpingogram: left hydrosalpinx**

**Table 14. Typical and Atypical Findings on a Sonohysterogram**

| Finding | Typical | Atypical |
|---|---|---|
| **Polyps** | A well-defined, homogeneous, polypoid lesion isoechoic to the endometrium with preservation of the endometrial-myometrial interface | Cystic components, multiple polyps, broad base, hypoechogenicity or heterogeneity |
| **Leiomyoma** | Well-defined, broad-based, hypoechoic, solid masses with shadowing. Overlying layer of endometrium is echogenic and distorts the endometrial-myometrial interface | Pedunculation or multilobulated surface |
| **Hyperplasia and Cancer** | Diffuse echogenic endometrial thickening without focal abnormality, although focal lesions can occur. Endometrial cancer is typically a diffuse process, but early cases can be focal and appear as a polypoid mass | |
| **Adhesions** | Mobile, thin, echogenic bands that cut across the endometrial cavity | Thick, broad-based bands that can completely obliterate the endometrial cavity, as in Asherman's syndrome |

# Adrenal Mass

- imaging modality: most often identified on CT scan as 'incidentaloma,' can also use CT/MRI to distinguish benign from malignant masses

**Table 15. Adrenal Mass Findings on CT and MRI**

| Factors | Adrenocortical Adenoma | Adrenocortical Carcinoma | Pheochromocytoma | Metastasis |
|---|---|---|---|---|
| **Diameter (CT)** | Usually ≤3 cm | Usually ≥4 cm | Usually >3 cm | Variable around <3 cm |
| **Shape (CT)** | Smooth margins and round/oval | Irregular with unclear margins | Round/oval with clear margins | Oval/irregular with unclear margins |
| **Texture (CT)** | Homogeneous | Heterogeneous with mixed densities | Heterogeneous with cystic areas | Heterogeneous with mixed densities |
| **Vascularity (CT)** | Not highly vascular | Usually vascular | Usually vascular | Usually vascular |
| **Washout of Contrast Medium on CT** | ≥50% at 10 min | <50% at 10 min | <50% at 10 min | <50% at 10 min |
| **Growth** | Stable or very slow (<1 cm/yr) | Usually rapid (>2 cm/yr) | Slow (0.5-1 cm/yr) | Variable |
| **Other Findings** | Usually low density due to intracellular fat | Necrosis, calcifications, and hemorrhage | Hemorrhage | Occasionally hemorrhage |
| **MRI on T2 Weighted Imaging** | Isointense in relation to liver | Hyperintense in relation to liver | Markedly hyperintense in relation to liver | Hyperintense in relation to liver |

# Neuroradiology

## Modalities

- CT is the modality of choice for most neuropathology; even under circumstances where MRI is preferred
- CT is frequently the initial study performed because of its speed, availability, and lower cost
  - acute craniofacial trauma: CT is best for visualizing "bone and blood"; MRI is used only when CT fails to detect an abnormality despite strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - acute headache with focal neurologic signs
  - suspected subarachnoid or intracranial hemorrhage
  - suspected hydrocephalus
  - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
  - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumours, respectively

### Skull Films

- rarely performed, generally not indicated for non-penetrating head trauma
- indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys, multiple myeloma

### CT

- indications: excellent study for evaluation of bony and intracranial abnormalities
- often done first without and then with IV contrast to show vascular structures or anomalies

**Modality Based on Neuropathology Presentation**

- Cognitive decline = CT
- Cord compression = MRI
- Decreased level of consciousness = CT
- Fish bone/other swallowed foreign body = CT
- Low back pain, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- Rule out bleed = CT
- Rule out aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

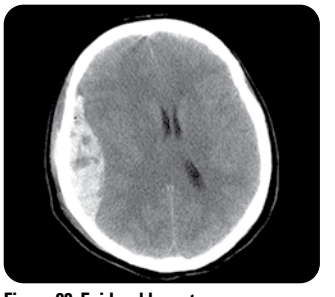

**Figure 28. Epidural hematoma**

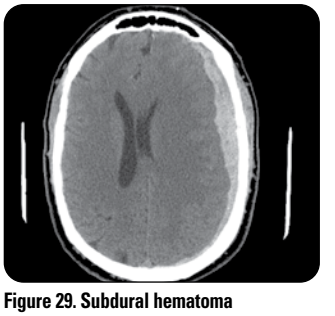

**Figure 29. Subdural hematoma**

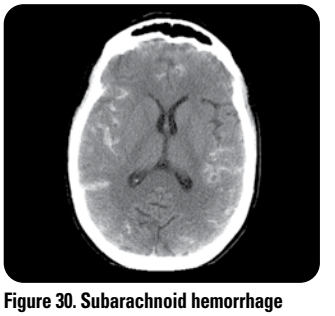

**Figure 30. Subarachnoid hemorrhage**

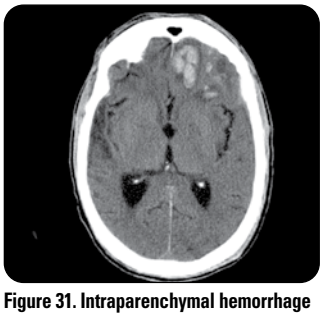

**Figure 31. Intraparenchymal hemorrhage**

- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or bright/show enhancement) with contrast injection
  - when in doubt, look for Circle of Willis or confluence of sinuses to determine presence of contrast enhancement
- posterior fossa can be obscured by extensive bony-related streak artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space-occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with current generation of multidetector CT scanners

### Myelography
- introduction of water-soluble, low-osmotic contrast media into subarachnoid space via lumbar puncture followed by x-ray
- largely replaced by MRI or CT myelogram
- indications: excellent study for disc herniation, traumatic nerve root avulsion, patients with contraindication to MRI

### MRI
- indications: finer neuroanatomic definition, better grey-white matter differentiation (especially T1-weighted series), better evaluation of edema extent (better tumour detection), allows evaluation of structures obscured by bony artifacts on CT (posterior fossa structures), multiplanar imaging helpful in pre-operative assessment

### Cerebral Angiography/CT Angiography/MR Angiography
- indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissections
- conventional digital subtraction angiography remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation confers risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without risk to intracranial or neck vessels
- MRA and CTA are often used first as 'screening tests' for the assessment of subarachnoid hemorrhage, vasospasm, or aneurysms

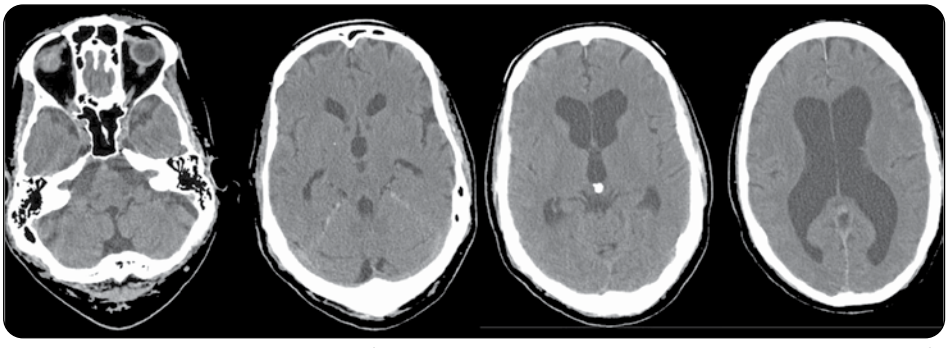

**Figure 32. Hydrocephalus: ventricular dilatation (may see periventricular low attenuation due to transependymal CSF flow)**

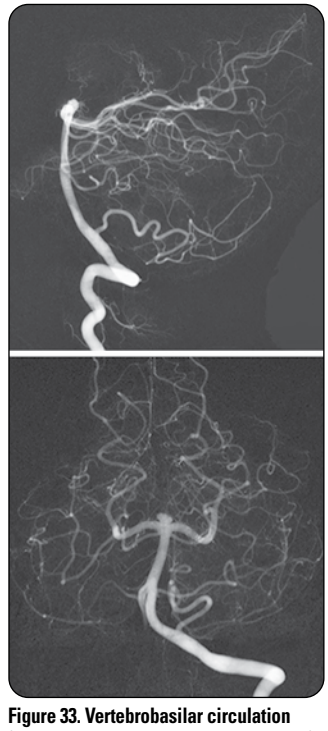

**Figure 33. Vertebrobasilar circulation**
(note the incidental basilar tip aneurysm)

**Table 16. Two Types of Hydrocephalus**

| Type | Cause |
|---|---|
| **Communicating/Extra-Ventricular** | Impaired CSF reabsorption with unobstructed flow in ventricular system; imaging shows all ventricles dilated |
| **Non-Communicating** | Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction |

### Nuclear Medicine
- SPECT imaging using $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) assesses cerebral blood flow, as radionuclides diffuse rapidly across the blood brain barrier and become trapped within neurons at a magnitude proportional to cerebral blood flow
- $^{18}$FDG PET imaging assesses cerebral metabolic activity
- indications: differentiation of residual tumour vs. radiation necrosis; localizing of epileptic seizure foci; evaluation of atypical dementia

## Approach to CT Head

- think anatomically, work from superficial to deep
- scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
- skin/soft tissue: examine the soft tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid gland, muscles of mastication (masseter, temporalis, pterygoids), visualize pharynx

**Approach to the CT Head**
**Some** = **S**can
**Sore** = **S**kin/**S**oft Tissue
**Brains** = **B**one/Airspace
**Demonstrate** = **D**ura/Subdural space
**Pushed** = **P**arenchyma
**Ventricles** = **V**entricles/Sulci/Cisterns

Transient ischemic attacks are not associated with radiological findings

- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for fractures or opacity that may suggest fluid, pus, blood, or tumour; status of the orbital floor in cases of facial trauma (coronal series best)
- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between grey and white matter suggests possible infarction, tumour, edema, infection, or contusion; hyperdensity in the parenchyma suggests enchancing lesions, intracerebral hemorrhage, or calcification; central grey matter nuclei (e.g. globus pallidus, putamen, internal capsule) should be visible, otherwise, suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour
- please refer to Toronto Notes website for supplementary material on how to approach a head CT

**Figure 34. Insular ribbon sign (left side)** Hypodensity of insular cortex representing early sign of infarction

# Selected Pathology

- see Neurosurgery, NS4 for intracranial mass lesions
- see Neurosurgery, NS31 for head trauma and Plastic Surgery, PL31 for craniofacial injuries
- see Emergency Medicine, ER9 for spinal trauma
- see Neurosurgery, NS24 and Orthopedic Surgery, OR23 for degenerative spinal abnormalities

## Cerebrovascular Disease (Neurosurgery, NS18)

- pathogenesis of stroke: see Neurosurgery, NS18
- best imaging modality: infarcts best detected by MRI > CT

**DDx for Ring Enhancing Cerebral Lesion**

**MAGIC DR**
**M**etastasis
**A**bscess
**G**lioblastoma multiforme
**I**nfarction (subacute/chronic)
**C**ontusion/hematoma
**D**emyelinating disease (e.g. MS)
**R**adiation necrosis

**Table 17. Temporal Findings of Infarction with CT and MRI**

| Time from Stroke Onset | CT | MRI |
|---|---|---|
| **Hyperacute (0-24 h)** | Usually normal within 6 h<br>Edema (loss of grey-white matter differentiation – "insular ribbon sign", effacement of sulci, mass effect)<br>Hyperattenuating artery "hyperdense MCA sign" repre-senting intravascular thrombus/emboli may be seen in ischemic stroke<br>Hyperattenuating acute blood surrounded by edema may be seen in hemorrhagic stroke | Hyperintensity on DWI within minutes of arterial occlusion due to restriction of water movement indicative of cytotoxic edema<br>Hypointensity on ADC within minutes<br>Hyperintensity on T2/FLAIR approximately 6 h after onset due to edema (loss of grey-white matter differentiation, effacement of sulci, mass effect) |
| **Acute (24 h-1 wk)** | Increasing edema (seen as hypoattenuation) may result in significant positive mass effect | Continued hyperintensity on DWI<br>Hypointensity on ADC reaches nadir at 3-5 d and begins to increase<br>Continued hyperintensity on T2/FLAIR |
| **Subacute (1-3 wk)** | Resolution of edema leads to increased attenuation of infarcted area that may regain near-normal density and mask stroke "fogging phenomenon" | Continued hyperintensity on DWI due to "T2 shine through"<br>Intensity on ADC continues to rise, pseudo-normalizes at 10-15 d, and then surpasses that of surrounding normal tissue<br>Continued hyperintensity on T2/FLAIR |
| **Chronic (>3 wk)** | Encephalomalacia (parenchymal volume loss) appears as hypoattenuation with negative mass effect | Hyperintensity on DWI/T2/FLAIR progressively decreases<br>ADC intensity remains elevated |

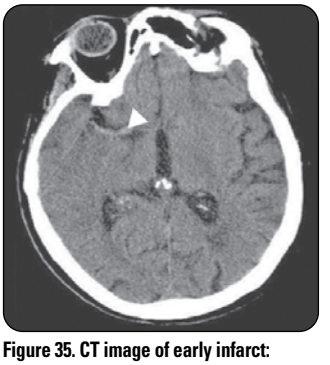

**Figure 35. CT image of early infarct: hyperdense artery**

- carotid artery disease
  - best imaging modality: Duplex (Doppler U/S)
  - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

## Multiple Sclerosis (see Neurology, N52)

- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
  - characteristic lesion on MRI is cerebral or spinal plaque
  - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum), centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  - "Dawson's fingers" refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be of use
  - perivascular and interstitial edema may be prominent

**Figure 36. DWI of patient with right frontotemporal infarct**

- spinal cord lesions typical of MS
  - little or no cord swelling
  - unequivocal hyperintensity on T2-weighted sequences
  - size at least 3 mm but less than 2 vertebral segments in length
  - occupy only part of the cord in cross-section
  - focal (i.e. clearly delineated and circumscribed on T2-weighted sequences)

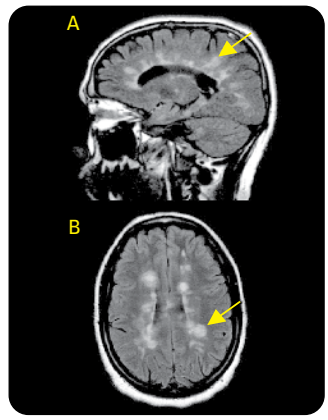

**Figure 37. T2-weighted FLAIR: (A) sagittal (B) axial images of multiple sclerosis with periventricular "Dawson's Fingers"**

### CNS Infections

- **meningitis**
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: *S. pneumoniae, H. influenzae, N. meningitidis, L. monocytogenes*
    - best imaging modality: MRI (T2-weighted/FLAIR)
    - findings
      - meningeal enhancement (following the gyri/sulci and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
  - a normal MRI does not rule out leptomeningitis
- **herpes simplex encephalitis** (see Infectious Diseases, ID17)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2-weighted)
  - findings
    - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
    - DDx: infarct, tumour, status epilepticus, limbic encephalitis
    - CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
    - long-term may show parenchymal loss to affected areas
- **cerebritis/cerebral abscess**
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: S. aureus (often in IV drug users, nosocomial), Streptococcus, Gram negative bacteria, Bacteroides
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2

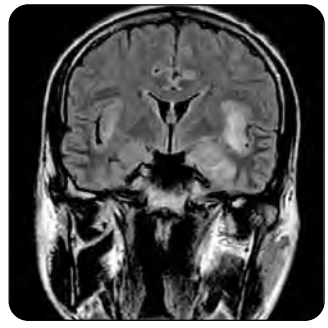

**Figure 38. T2-weighted (FLAIR) coronal image of herpes simplex virus encephalitis affecting temporal lobes**

# Musculoskeletal System

## Modalities

- see *Imaging Modalities*, MI2 for advantages and disadvantages of the following:

### Plain Film/X-Ray

- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malunion or nonunion, orthopedic hardware, and bone lesions (initial)
- minimum of two orthogonal views (usually AP and lateral) to rule out a fracture
- image proximal and distal joints, particularly important with paired bones (e.g. radius/ulna)
- minimally effective in evaluating soft tissue injury

### CT

- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular, or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification

### MRI

- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses, infection of bone (osteomyelitis)

### Ultrasound
- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, U/S-guided biopsy and injections, bone/joint evaluation pre-ossification (e.g. DDH in early months)
- Doppler determines vascularity of structures

### Nuclear Medicine (Bone Scintigraphy)
- determine the location and extent of bony lesions
- $^{99m}$Tc-methylene diphosphonate localizes to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget's), sites of reactive bone formation, and periostitis
- advantages: very sensitive, capable of imaging entire body with relatively low dose radiation
- disadvantages: low specificity, not widely available due to special requirements (e.g. gamma camera, radiopharmaceuticals)

## Approach to Bone X-Rays

- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges, or borders of any lesions

**Figure 39. X-ray findings of first carpometacarpal joint:** normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

## Trauma

### Fracture/Dislocation
- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR5

## Arthritis

### Radiographic Hallmarks of Osteoarthritis
- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

### Radiographic Hallmarks of Rheumatoid Arthritis
- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

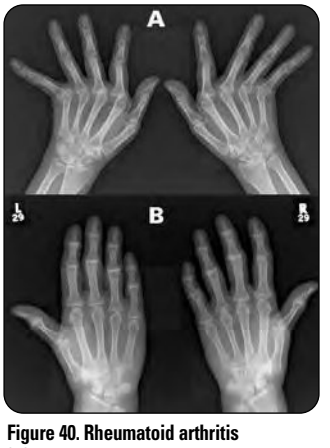

**Figure 40. Rheumatoid arthritis (A) compared with osteoarthritis (B) X-ray findings**

## Bone Tumour

### Approach
- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 yr
  - diagnosis usually requires a biopsy if primary not located
  - few benign tumours/lesions have potential for malignant transformation
  - MRI is good for tissue delineation and pre-operative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
  - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

### Considerations and Tumour Characteristics
- for specific bone tumours, see Orthopedic Surgery, OR46
- age: most common tumours by age group
  - <1 yr of age: metastatic neuroblastoma
  - 1-20 yr of age: Ewing's sarcoma in tubular bones
  - 10-30 yr of age: osteosarcoma and Ewing's tumour in flat bones
  - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
  - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
  - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
  - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumours, eosinophilic granuloma, Ewing's sarcoma

- expansile
  - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
- matrix mineralization
  - chondroid (popcorn calcification) or osseous
- margin/zone of transition: area between lesion and normal bone
- cortex: intact, disturbed
- periosteal reaction: onion-skinning, sunburst, Codman's triangle, periosteal neocortex
- soft tissue mass

**Benign Lesions which may have Aggressive Features**
- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

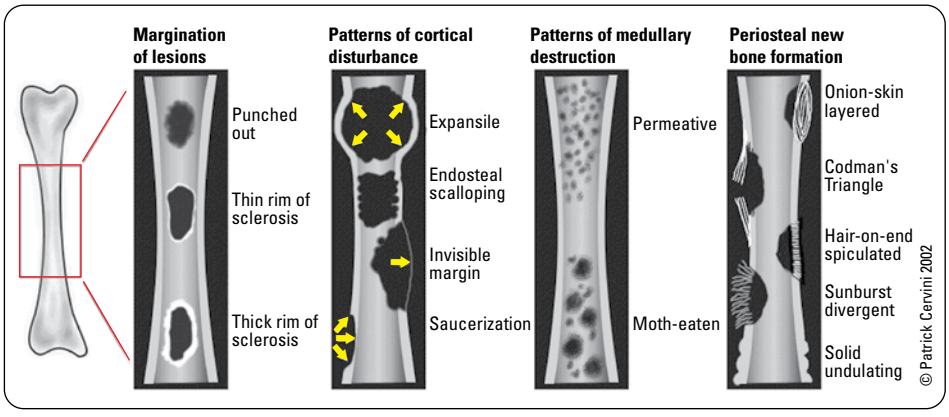

**Figure 41. Radiographic appearance of bone remodelling and destruction processes**

**Periosteal Reaction**
- "Onion skinning" = Ewing's sarcoma
- "Sunburst", "hair on end" = osteosarcoma
- "Codman's triangle" = osteosarcoma, Ewing's sarcoma, subperiosteal abscess

**Table 18. Characteristics of Benign and Malignant Bone Lesions**

| Benign | Malignant |
|---|---|
| Thin sclerotic margin/sharp delineation of lesion | Poor delineation of lesion – wide zone of transition |
| Overlying cortex intact | Loss of overlying cortex/bony destruction |
| No or simple periosteal reaction | Periosteal reaction |
| No invasion of surrounding soft tissue | Invasion of surrounding soft tissue |

## Metastatic Bone Tumours

Lytic = decreased density
Sclerotic = increased density

- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumours
- metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial workup
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- most common metastatic bone tumours: breast, prostate, lung, see Orthopedic Surgery, OR46

**"KLM flies to periphery"**

**K**idney
**L**ung
**M**elanoma

**Table 19. Characteristic Bone Metastases of Common Cancers**

| Lytic | Sclerotic | Expansile | Peripheral |
|---|---|---|---|
| Breast | Prostate | Thyroid | Kidney |
| Lung | Breast | Renal | Lung |
| Thyroid | Lymphoma | | Melanoma |
| Kidney | Lung | | (KLM: flies to the periphery) |
| Multiple myeloma | Bowel | | |
| | Medulloblastoma | | |
| | Treated tumours | | |

# Infection

## Osteomyelitis

- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- $^{99m}$Tc, followed by $^{111}$In-labeled white cell scan or gallium radioisotope scan
- plain film changes visible 8-10 d after process has begun
  - soft tissue swelling
  - local periosteal reaction
  - pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fasciitis
  - mottled and nonhomogeneous with a classic "moth-eaten" appearance
  - endosteal scalloping
  - cortical destruction
  - peripheral sclerosis (late sign)

### Bone Abscess
- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie's abscess (rare form of osteomyelitis on bone metaphyses)
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone
- best imaging modality: MRI for bone, bone marrow, and soft tissue abnormalities; CT for sequestra and cortical erosions

## Metabolic Bone Disease

### Osteoporosis
- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- DEXA: gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: –2.5< T-score <–1
    - osteoporosis: T-score ≤–2.5
  - Z-score: the number of standard deviations from the age-matched mean, helpful in diagnosing secondary osteoporosis
  - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
  - diagnostic sensitivity of DEXA highest when bone mineral density measured at lumbar spine and proximal femur
- appearance on plain film (not sensitive; changes detectible only after large reduction in bone mineral density)
  - osteopenia: reduced bone density on plain films
    - may also be seen with osteomalacia, hyperparathyroidism, and disuse
  - compression of vertebral bodies
  - "codfish vertebra" (biconcave vertebral bodies), "picture frame vertebra" (cortical loss), "ghost vertebra" (trabecular loss)
  - long bones have appearance of thinned cortex and increased medullary cavity
    - look for complications of osteoporosis (e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami)
- see Endocrinology, E43

**Osteoporosis**
Reduced amount of bone

**OsteoMalacia**
Normal amount of bone, but reduced **M**ineralization of normal osteoid

### Osteomalacia/Rickets
- reduction in bone mineral density; normal amount of bone, but reduced mineralization of normal osteoid
- usually due to vitamin D deficiency, resulting in softening and bowing of long bones
- similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
- "fuzzy", ill-defined trabeculae
- insufficiency fractures
- Looser's zones (pseudofracture)
  - characteristic radiologic feature
  - fissures or clefts at right angles to long bones and extending through cortex
  - DDx: chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget's, osteodystrophy, X-linked hypophosphatemia

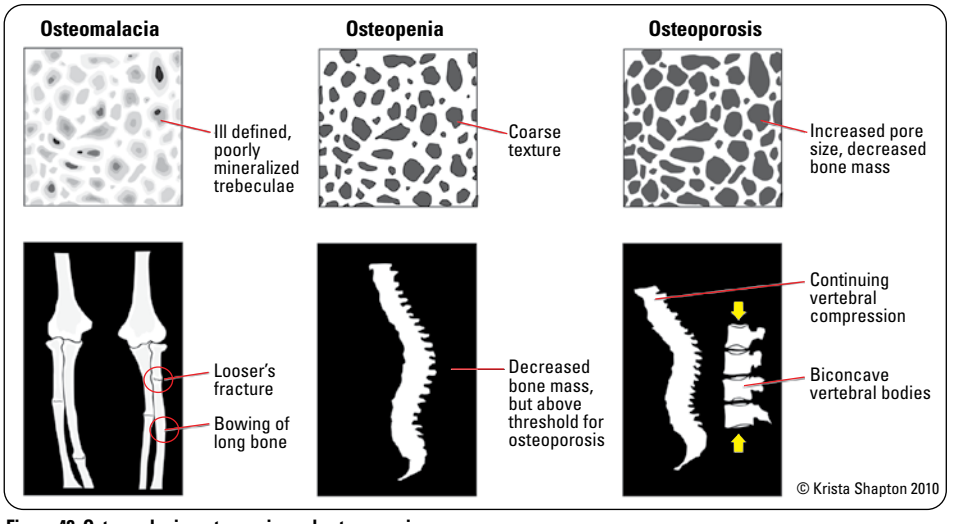

**Figure 42. Osteomalacia, osteopenia, and osteoporosis**

### Hyperparathyroidism
- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis is a common complication
- calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and peri-articular soft tissue)
- resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull ("salt and pepper" appearance), subligamentous resorption (ischial tuberosity, trochanters, and clavicle), osteoclastoma (brown tumours)
- "rugger jersey spine": band-like osteosclerosis at superior/inferior margins of vertebral bodies

### Paget's Disease
- abnormal remodelling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- coarsening of the trabeculae with bone expansion
- bone softening/bowing
- bone scan will reveal high activity
- thickened cortex
- see Endocrinology, E46

# Nuclear Medicine

## Brain

- $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism, taken up predominantly in grey matter
  - used for dementia, traumatic brain injury, and to a lesser extent vasculitis, neuropsychiatric disorders, and occasionally stroke
  - most commonly used tracers to confirm brain death (i.e. absent blood flow to the brain and absent uptake on delayed planar and SPECT images in brain and brainstem, assuming study is technically adequate)
  - either tracer can be used for seizure imaging to assess for the most likely location of epileptogenic focus, but usually must be made available for 24 h and the patient followed by a nurse who is competent to administer the activity at the time of seizure
- PET imaging assesses metabolic activity most commonly with $^{18}$FDG; used for dementia imaging, grading and staging of brain tumours, occasionally for seizure disorder imaging, and vasculitis; PET imaging with amyloid tracers for diagnosis of Alzheimer's disease is becoming more common
- CSF imaging, intrathecal administration of $^{111}$In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy
- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free $^{99m}$Tc (usually) or $^{111}$In-DTPA; small quantity of activity is injected into the reservoir under sterile conditions and should flow freely into the peritoneal cavity by 45 min; maneuvers such as pumping the shunt, sitting the patient upright or ambulating are acceptable to encourage flow during this time
- adrenergic imaging of the heart with MIBG has been used to differentiate dementias with autonomic dysfunction (i.e. Lewy Body and Parkinson's disease) from other forms of dementia (i.e. autonomic impairment associated with decreased MIBG activity in the heart)

## Thyroid

### Radioactive Iodine Uptake (see Endocrinology, E23)
- index of thyroid function (trapping and organification of iodine)
- radioactive $^{123}$I given PO to fasting patient (small quantity)
- measure percentage of administered iodine taken up by thyroid
- increased RAIU: toxic multinodular goitre, toxic adenoma, Graves' disease
- decreased RAIU: subacute thyroiditis, late Hashimoto's disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking a "thyroid vitamin")
- important – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism (exception is pediatrics)

### Thyroid Imaging (Scintiscan)
- $^{99m}$Tc-pertechnetate IV or radioactive iodine ($^{123}$I); most Canadian sites use pertechnetate to reduce cost
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer unlikely (<1%) – No FNA
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous; decision to biopsy should be based on clinical and sonographic features
- isointense i.e. "warm" lesions: cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

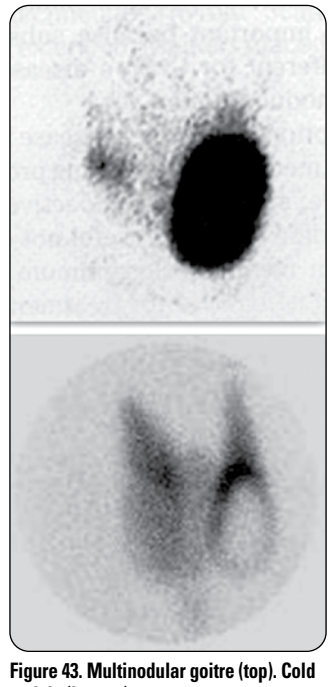

**Figure 43. Multinodular goitre (top). Cold nodule (bottom)**

### Radioiodine Ablation
- $^{131}I$ for Graves' disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient who has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

### Pediatric Hypothyroidism
- pertechnetate thyroid scan can differentiate thyroid agenesis, hemiagenesis, lingular thyroid, organification defect, however should not wait for a diagnosis to start thyroid hormone replacement in a neonate; start immediately

## Respiratory

### V/Q Scan
- evaluate areas of lung in which there is a ventilation/perfusion mismatch
- ventilation scan – assess air flow within lungs
  - patient breathes radioactive gas (nebulized $^{99m}Tc$-DTPA, $^{133}Xe$, or most commonly Technegas) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction
- perfusion scan – assess blood circulation within lungs
  - radiotracer injected IV ($^{99m}Tc$-MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
  - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, small child. In these cases fewer particles are usually given
- to rule out PE
  - indications: some institutions favour in pregnancy (lower radiation dose to breast than CT), or where CT contrast contraindicated (e.g. contrast allergy, renal failure)
  - areas of lung that are well-ventilated but not perfused (unmatched defect) are suspicious for acute infarction
  - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
  - often reported as high probability (>2 large i.e. segmental mismatched perfusion defects), intermediate, low, very low, or normal according to modified PIOPED II criteria, although are increasingly reported as PE present, indeterminate or normal
  - useful in finding clinically important emboli
  - decreased detection of incidentalomas commonly found on CT
- not valid for assessment of PE when patients have consolidation and the test can be limited by ventilatory problems (e.g. COPD), much like CT
- modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

**Ventilation Scan Defects Indicate…**
ABC Tumour
Airway obstruction
Bronchospasm
Chronic lung disease
Tumour mass obstruction

**Perfusion Scan Defects Indicate…**
Reduced blood flow due to PE
COPD
Asthma
Bronchogenic carcinoma
Inflammatory lung diseases (pneumonia, sarcoidosis)
Mediastinitis
Mucous plug
Vasculitis

**V/Q Scan**
For PE investigation: normal scan makes PE unlikely
Probability of PE: high 80-100%, intermediate 20-80%, low <20%, very low <10%

## Cardiac

### Myocardial Perfusion Scanning
- to investigate coronary artery disease (CAD), assess treatment of CAD, pre-op risk stratification, viability testing
- $^{99m}Tc$-sestamibi, or $^{99m}Tc$-tetrofosmin are used most commonly, thallium 201 was used previously but largely discontinued due to high radiation doses to patients and unfavourable imaging characteristics; today thallium still used for viability studies
- injected at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes), after persantine challenge (vasodilator), or after dobutamine infusion (chronotropic, again to 85% predicted heart rate); can be done as stress only protocol with optional rest or as stress and rest combined protocol (i.e. as 1 d or 2 d protocol)
- patients with left bundle branch block usually given pharmacologic stress because ECG is difficult to interpret for ST changes and avoids a characteristic artifact
- pharmacologic stress contraindicated if sBP is <90; persantine exacerbates asthma, so patients with asthma and wheeze who cannot exercise usually get dobutamine infusion; reverse persantine with aminophylline or caffeine
- persistent defect (present at rest and stress) suggests infarction or myocardial scar; reversible defect (only present during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- COURAGE trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see Cardiology and Cardiac Surgery, C13

### Radionuclide Ventriculography
- $^{99m}$Tc-tagged to red blood cells, tagged albumin is also acceptable
- first pass through RV → pulmonary circulation → LV; provides information about RV function, presence of shunts
- cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
- evaluation of LV function and regional wall motion, ejection fraction
- images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
- can assess diastolic dysfunction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion
- indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator workup

## Abdomen and Genitourinary System

### HIDA Scan (Cholescintigraphy)
- IV injection of $^{99m}$Tc-disofenin (DISIDA) or $^{99m}$Tc-mebrofenin which is bound to protein, taken up, and excreted by hepatocytes into biliary system
- can be performed in non-fasting state but prefer NPO after midnight
- indicated in workup of cholecystitis when abdominal ultrasound result is equivocal:
  - acute cholecystitis: no visualization of gallbladder at 4 h or 1 h after administration of morphine
  - chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- gallbladder visualized when cystic duct is patent (rules out acute cholecystitis with >99% certainty), usually seen by 30 min-1 h
- differential diagnosis of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
- also used to assess bile leaks post-operatively or in trauma
- gallbladder ejection fraction (>38% is normal) can be measured after a fatty meal or cholecystokinin to assess for biliary dyskinesia

### RBC Scan
- IV injection of radiotracer with sequential images of the abdomen ($^{99m}$Tc RBCs)
- GI bleed
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image, requires active bleeding to localize (more sensitive than angiography in detecting slower bleeding)
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific, better for localizing, both diagnostic and therapeutic)
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills in later (accumulation of tagged cells greater than surrounding liver parenchyma)

### Other Important Nuclear Medicine Abdominal Tests
- Meckel's Scan: uses $^{99m}$Tc pertechnetate; give patient ranitidine premedication; Meckel's diverticulum contains gastric mucosa which will light up at the same time as the stomach and get brighter with time like stomach
- $^{111}$In octreoscan: a somatostatin analog used for evaluation and staging of neuroendocrine tumours including carcinoid; gastrinoma and carcinoid tend to be more octreotide avid than insulinoma
- iodinated MIBG: a norepinephrine analogue, used for pheochromocytoma, neuroblastoma and medullary thyroid cancer most commonly; limited cardiac applications as above
- solid and liquid gastric emptying: a standardized solid or liquid meal is labelled, usually with $^{99m}$Tc sulfur colloid and gastric emptying studied over time. There are normal ranges for solids and liquids

### Urea Breath Test
- indication: diagnosis of gastric *H. pylori* infection
- patient administered 14C-labelled urea orally, urea metabolized by *H. pylori* to ammonia and $14CO_2$, 14C-labled $CO_2$ is measured via plastic filament detectors or liquid scintillation

### Functional Renal Imaging
- evaluation of renal function and anatomy using $^{99m}$Tc DTPA or $^{99m}$Tc MAG3
- frequently used to provide index of relative function between two kidneys
- frequently used in adults to assess for UPJ obstruction (by assessing the clearance half time with furosemide), and assess renal transplants or as a nuclear GFR study in patients wanting to donate kidneys
- in children, imaging with $^{99m}$Tc DMSA is used to assess for pyelonephritis
- in children, the injection of tracer into the bladder via foley catheter is often used to assess for reflux

# Bone

### Bone Scan
- isotopes, usually $^{99m}$Tc-diphosphonate
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone pain of unknown origin, staging or restaging of cancer with boney mets (or primary bone cancer), imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
- when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- differential diagnosis of positive bone scan: bone metastases (primary breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget's disease
- lytic lesions like multiple myeloma, renal cell cancer, eosinophilic granuloma: typically normal or cold (false negative); need a skeletal survey
- "superscan": increased bone uptake and poor renal uptake due to diffuse metastases (primary breast, prostate) or metabolic causes (e.g. renal osteodystrophy)

# Interventional Radiology

## Vascular Procedures

### Angiography
- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a "flush" or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- often used in the operating room to provide fluoroscopic guidance for exposure of diseased vessel
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see *Neuroradiology*, MI18

Advanced ischemia patients should receive surgery rather than thrombolysis

### Percutaneous Transluminal Angioplasty and Stents
- introduction and inflation of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5 yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty; also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
- complications: similar to angiography, but also includes vessel rupture

Chemoembolization delivers chemotherapy directly into the tumour through its feeding blood supply and traps the drug in place by embolization

### Thrombolytic Therapy
- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
- complications: bleeding, stroke, distal embolus, reperfusion injury in delayed intervention with myoglobinuria and renal failure if advanced ischemia present

**Thrombolytic Therapy for Pulmonary Embolism**
Cochrane Database Syst Rev 2015;9:CD004437
**Purpose**: To assess the effects of thrombolytic therapy in patients with acute pulmonary embolism (PE).
**Methods**: Systematic review of RCTs evaluating thrombolytic therapy followed by heparin versus heparin alone, heparin plus placebo or surgical intervention in patients with acute PE. Studies comparing two different thrombolytic agents or different doses of the same thrombolytic drug were not considered eligible. Main outcomes of interest were death, recurrence of PE, and major and minor hemorrhagic events.
**Results**: Eighteen trials with2197 participants were included. Thrombolytics plus heparin were associated with a reduction in odds of death relative to heparin alone or heparin plus (OR 0.57, 95% CI 0.37 to 0.87, P = 0.02) and recurrence of PE (OR 0.51; 0.29 to 0.89, P = 0.02). Incidence of major and minor hemorrhagic events was statistically significantly higher in the thrombolytics group than the control group (OR 2.90, 95% CI 1.95 to 4.31, P <0.001). Length of hospital stay (mean difference (MD) -1.35, -4.27 to 1.58) and quality of life were similar between groups. Based on one study, stroke occurred more often in the thrombolytics group (OR 12.10, 1.57 to 93.39).
**Conclusion**: Low-quality evidence suggests thrombolytics reduce death following acute PE compared with heparin and may be helpful in reducing PE recurrence, but may cause more major and minor hemorrhagic events and stroke events.

### Embolization
- injection of occluding material into vessels
- permanent agents: amplatzer plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

### Inferior Vena Cava Filter
- insertion of temporary or permanent metallic "umbrellas" to mechanically trap emboli and prevent PE
- inserted via femoral vein, jugular vein, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

**Figure 44. Retrievable IVC filter**

### Central Venous Access
- variety of devices available
- PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®)
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis, central venous stenosis, infection including sepsis, and pneumothorax

**Indications for Central Venous Access**

**FAT CAB**
**F**luids
**A**ntibiotics
**T**PN
**C**hemotherapy
**A**dministration of blood
**B**lood sampling

## Nonvascular Interventions

### Percutaneous Biopsy
- alternative to open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy, CT or MR guidance
- complications: false negative (sampling error or tissue necrosis), needle tract seeding, hemorrhage (particularly for splenic biopsies), pneumothorax in 30% of lung biopsies (chest tube required in ~5%), acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

### Abscess Drainage
- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening and nearby structures (e.g. bowel), bacteremia, sepsis, failure to access

### Percutaneous Biliary Drainage/Cholecystostomy
- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
  - cholecystostomy: acute cholecystitis
  - PBD: biliary obstruction secondary to stone or tumour, cholangitis, acute biliary pancreatitis
- complications
  - acute: sepsis, hemorrhage
  - long-term: tumour ingrowth and stent occlusion

**Figure 45. Femoral arteriogram: distal occlusion of superficial femoral artery**

### Percutaneous Nephrostomy
- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteremia and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

### Gastrostomy/Gastrojejunostomy
- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: inability to eat (most commonly CNS dysfunction, e.g. stroke), esophageal obstruction, or decompression in gastric outlet obstruction
- complications: gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

### Radiofrequency Ablation
- U/S- or CT-guided probe is inserted into tumour, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours
- complications: destruction of neighbouring tissues and structures, bleeding, periprocedural embolism

# Breast Imaging

## Modalities

### Mammography

#### Description

- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General Surgery, GS61)
- routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

#### Indications

- screening
  - begin screening from age 50 q2-3yr
  - no strong data to support screening >70 yr, but may continue screening if in good general health
  - if <50, screening is only recommended for those with high risk of breast cancer
  - screening detects 2-8 cancers/1000 women screened
- surveillance
  - follow-up of women with previous breast cancer
- diagnostic: includes mammography with special views and/or ultrasound
  - workup of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, overlying skin changes, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - suspected complications of breast implants

**Table 20. Breast Imaging Reporting and Data System (BI-RADS®) Mammography Categories**

| Assessment Categories | Imaging Findings | Follow-Up Recommendations |
|---|---|---|
| **BI-RADS 0** | Incomplete | Additional imaging<br>Comparison to prior films |
| **BI-RADS 1** | Negative | Routine screening |
| **BI-RADS 2** | Benign | Routine screening |
| **BI-RADS 3** | Probably benign<br>Likelihood of malignancy is <2% | Unilateral mammogram at 6 mo |
| **BI-RADS 4** | Suspicious abnormality | Biopsy |
| **BI-RADS 5** | Highly suspicious of malignancy<br>Likelihood of malignancy is 95% | Biopsy |
| **BI-RADS 6** | Malignancy confirmed by biopsy | Definitive therapy |

### Breast Ultrasound

#### Indications

- characterization of palpable abnormalities
  - ultrasound is 1st line in <30 yr – denser breast tissue makes mammograms less sensitive in young females
  - 1st line in lactating and pregnant women
  - >30 yr need mammogram first
- further characterization of mammographic findings
- guidance for interventional procedures

### Breast MRI

#### Description

- contrast-enhanced MRI of the breasts
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- for diagnosis, used only after mammography and U/S investigation
- use as a screening modality is limited to high-risk patients, in conjunction with mammography

#### Indications

- "problem-solving" of indeterminate findings following complete mammographic and ultrasound workup
- evaluation of occult primary in patients presenting with axillary metastases
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy

- high-risk screening
  - known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer, or untested first-degree relative of a carrier of such a gene mutation
  - family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
  - high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma *in situ*)
  - radiation therapy to chest (before age 30)

# Breast Interventional Procedures

### Description
- includes fine needle aspirate biopsy, core needle biopsy, stereotactic biopsy, MRI guided biopsy, abscess drainage, and cyst aspiration

### Indications
- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5)
- suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) – stereotactic biopsy
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical wire localization of a lesion

# Breast Findings

### Breast Masses
- **definition**: a space-occupying lesion seen in two different projections; if seen in only a single projection it should be called an "asymmetry" until its three-dimensionality is confirmed

**Table 21. Mammographic Features of Benign and Malignant Breast Masses**

| | Benign | Malignant |
|---|---|---|
| **Shape** | Oval, round, lobular | Irregular |
| **Margin** | Circumscribed, well-defined | Indistinct, microlobulated, spiculated |
| **Density** | Radiolucent (oil cyst, lipoma, fibrolipoma, galactocele, hamartoma) | Radiodense |
| **Calcifications (± mass)** | Popcorn (hyalinizing fibroadenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered | Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogeneous, regional, segmental, clustered |

### Other Findings
- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
- if focal compression shows mass-like character – or if the area can be palpated – biopsy generally recommended

| RPF | renal plasma flow |
| RPGN | rapidly progressive glomerulonephritis |
| RRT | renal replacement therapy |
| RTA | renal tubular acidosis |
| SIADH | syndrome of inappropriate antidiuretic hormone |
| SLE | systemic lupus erythematosis |
| TBW | total body water |
| TIN | tubulointerstitial nephritis |
| TTP | thrombotic thrombocytopenic purpura |
| UAG | urine anion gap |
| UTI | urinary tract infection |

# Basic Anatomy Review

## Embryology of the Kidney

- intermediate mesodermic origin
- pronephros (from nephrogenic cord growing caudally towards cloaca) develops at the end of week 3 and then degenerates along with adjacent pronephric duct
- mesonephros develops in 4th week, degenerates, and the remnants form the mesonephric (Wolffian) duct of the male reproductive system
- metanephros develops in the 5th week from the ureteric bud in the mesonephric duct into the metanephric (mesoderm-derived) mass
  - ureteric bud → ureters, renal pelvis, calyces, collecting ducts
  - metanephric mass → nephrons (from glomeruli to the DCT)
  - kidneys ascend from the pelvis into the retroperitoneum rotating medially while ascending, and gaining a blood supply from the renal arteries as they ascend

## Renal Structure and Function

### The Nephron

- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

**Table 1. Major Kidney Functions**

| Function | Mechanism | Affected Elements |
|---|---|---|
| **1. Waste Excretion** | Glomerular filtration | Excretion of nitrogenous products of protein metabolism (urea, Cr) |
| | Tubular secretion | Excretion of organic acids (urate) and organic bases (Cr) |
| | Tubular catabolism | Breakdown and excretion of drugs (antibiotics, diuretics) and peptide hormones (most pituitary hormones, insulin, glucagon) |
| **2. Electrolyte Balance and Osmoregulation** | Tubular NaCl and water reabsorption | Controls volume status and osmolar balance |
| | Tubular $K^+$ secretion | Controls potassium concentration |
| | Tubular $H^+$ secretion | Acid-base balance |
| | $HCO_3^-$ synthesis and reabsorption | Acid-base balance |
| | Tubular $Ca^{2+}$, $Mg^{2+}$, $PO_4^{3-}$ transport | Alters $Ca^{2+}$, $Mg^{2+}$, $PO_4^{3-}$ homeostasis |
| | Synthesize osmolytes | Increase osmolality of medullary cytoplasm to match medullary concentration gradient |
| **3. Hormonal Synthesis** | Erythropoietin production (cortex) | Red blood cell production |
| | Vitamin D activation: 25(OH)VitD converted to 1,25$(OH)_2$VitD (proximal tubule) | Calcium homeostasis |
| | Renin production (juxtaglomerular apparatus) | Alters vascular resistance and aldosterone secretion |
| **4. Blood Pressure Regulation** | $Na^+$ excretion | Alters ECF volume |
| | Renin production | Alters vascular resistance |
| **5. Glucose Homeostasis** | Gluconeogenesis (from lactate, pyruvate, and amino acids) | Glucose supply maintained in prolonged starvation |
| | Clearance and degradation of circulating insulin | Maintains glucose homeostasis |

## The Glomerulus

- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman's space
- there is a filtration barrier to albumin due to its size and negative charge. The negative charge of the GBM repels the negatively charged albumin
- consists of following cell types:
  1. Mesangial cells
     - structural cells that support the glomerular capillaries; also has contractile activity and can alter GFR
     - also secretory cells under physiological and pathophysiological conditions, secreting matrix components, pro- and anti-inflammatory cytokines and chemokines
  2. Capillary endothelial cells
     - one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their sinusoidal nature and glycocalyx; contribute to the production of the GBM
     - interface with blood – target for antibodies and contact site for neutrophils, lymphocytes
3. Visceral epithelium (podocytes)
   - one of the cells of the glomerular filtration barrier; helps form the plasma filtration apparatus due to their interdigitated foot process forming slit diaphragms; contribute to the production of extracellular matrix proteins (collagen and laminin) making up the GBM
  4. Parietal epithelium
     - lines the interior of Bowman's capsule and contains a podocyte progenitor population
  5. Juxtaglomerular cells
     - smooth muscle cells in lining of afferent arteriole; produce, store and secrete renin

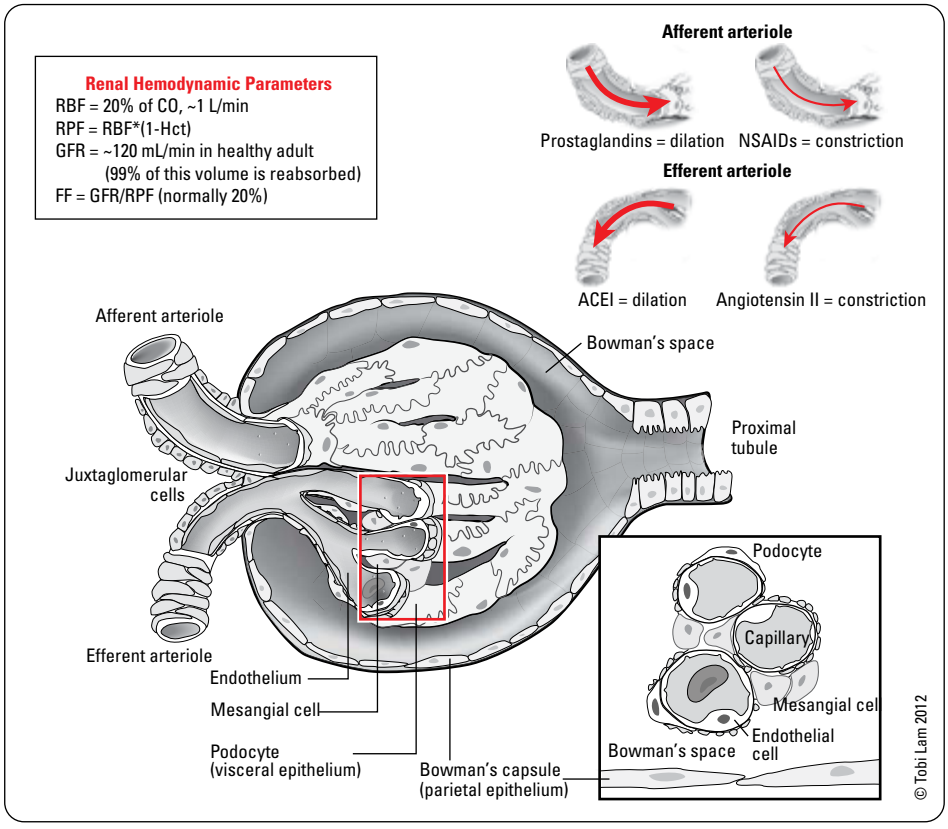

**Figure 1. The glomerulus**

## The Renal Tubules

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics

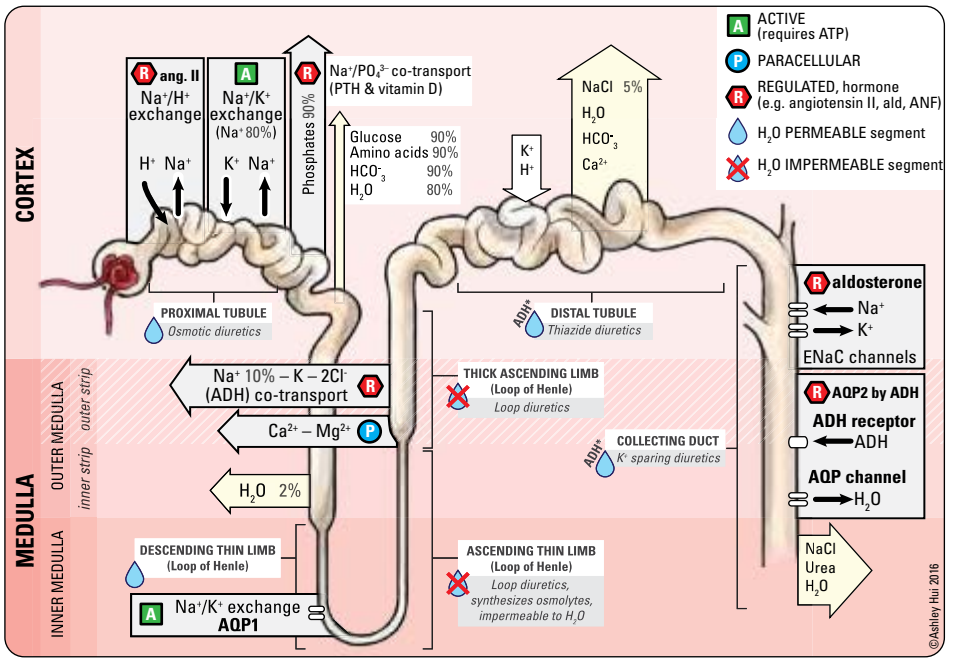

**Figure 2. Tubular segments of the nephron**

# Renal Hemodynamics

- GFR
  - GFR is the sum of the filtration across all nephrons
  - the rate of fluid transfer between glomerular capillaries and Bowman's space
  - average GFR of 180 L/d or 125mL/min/1.73m$^2$, of which 99% of the filtrate is reabsorbed
  - normal urine output is 0.5-2.0 mL/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter starting around age 40
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation to maintain GFR homeostasis
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. low GFR → decreased perfusion pressure → release of prostaglandin → afferent arteriolar dilation → increased GFR)
  - tubuloglomerular feedback: changes in $Na^+$ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. high GFR → increased $Na^+$ delivery → afferent constriction → decreased GFR)
- Filtration fraction
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
  - angiotensin II constricts renal efferent arterioles which increases FF, thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to decreased RPF and maintains sodium balance
  - renin is an important enzyme in the renin angiotensin aldosterone system, that converts angiotensinogen to angiotensin I

**Glomerular Filtration Rate**
GFR = Kf ($\Delta P - \Delta \Pi$)
Kf = ultrafiltration coefficient
$\Delta P$ = hydrostatic pressure difference between glomerular capillaries and Bowman's space
$\Delta \Pi$ = osmotic pressure difference between glomerular capillaries and Bowman's space
$\Delta P - \Delta \Pi$ = net outward pressure

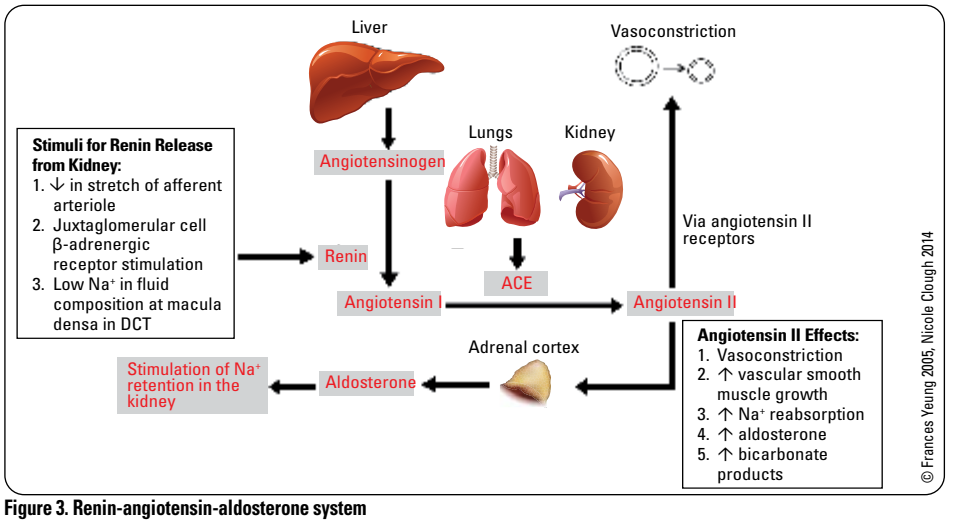

**Figure 3. Renin-angiotensin-aldosterone system**

# Assessment of Renal Function

## Measurement of Renal Function

- clinically, GFR is estimated using serum creatinine concentration, [Cr]
- inulin clearance and iothalamate radiotracer are the gold standard for measuring GFR, but very rarely used clinically
- most renal functions decline in parallel with a decrease in GFR
- Cr is a metabolite of creatine phosphate (intermediate in muscle metabolism), therefore increased muscle mass increases Cr production (thus the need to use body mass, ethnic origin, age, and gender in order to estimate GFR)
- Cr is freely filtered at the glomerulus with little tubular reabsorption
- tubular secretion of Cr varies based on level of renal function (10% to >50%)
- Cr filtered ≈ Cr excreted (at steady state)

### Ways to Estimate GFR Using Serum Creatinine Concentration

1. Estimate GFR using CKD-EPI equation
   - the best current equation
   - calculated using serum Cr, age, sex, and race
   - overestimate GFR
2. Estimate GFR using MDRD formula
   - most common way in which GFR is estimated (MDRD 7 equation)
   - complex formula incorporating age, gender, serum Cr, and race, but does not include weight
   - GFR is reported as mL/min/1.73 $m^2$ body surface area
   - underestimation of GFR at near normal values
3. Measure CrCl – 24 h urine collection
   - calculation provides reasonable estimate of GFR
   - GFR/d = (urine [Cr] x 24 h urine volume)/(plasma [Cr])
   - must use same units for urine [Cr] and plasma [Cr]
4. Estimate CrCl using Cockcroft-Gault formula
   - serum Cr used along with age, gender, and weight (kg) to estimate GFR (but does not include race)
   - overestimates GFR when renal function severely impaired
   - does not account for variations in body tissue composition

### Limitations of Using Serum Cr Measurements

1. must be in steady state
   - constant GFR and rate of production of Cr from muscles
   - sudden injury (e.g. AKI) may reduce GFR substantially, however, serum Cr will not immediately reflect sudden reduction in GFR until new Cr steady-state is reached
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
   - with progressive renal failure, remaining nephrons compensate with hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
   - lower production with smaller muscle mass (e.g. female, elderly, low weight)
     - for example, consider plasma [Cr] of 100 µmol/L in both of these patients
       - 20 yr old lean man who weighs 100 kg, GFR = 144 mL/min
       - 80 yr old woman who weighs 50 kg, GFR = 30.6 mL/min
   - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
   - serum Cr and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement
   - very high bilirubin level causes [Cr] to be falsely low
   - acetoacetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

### Measurement of Urea Concentration

- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes increase in urea level
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and µmol/L for Cr)

$Cr_{filtered} = Cr_{excreted}$

$[Cr]_{plasma} \times GFR = [Cr]_{urine} \times$ urine flow rate (mL/min)

$GFR = \frac{[Cr]_{urine} \times \text{urine flow rate}}{[Cr]_{plasma}}$

At steady state $[Cr]_{serum} \propto 1/CrCl$

**Cockcroft-Gault Formula**

$CrCl\ (mL/min) = \frac{(\text{weight in kg})\ (140-\text{age}) \times 1.23}{(\text{serum creatinine } (\mu mol/L)}$

Multiply above by 0.85 for females

**MDRD Equation**

$GFR\ (mL/min/1.73\ m^2) = 186 \times (CrS)^{-1.154} \times (Age)^{-0.203} \times (0.742 \text{ for females}) \times (1.212 \text{ if black})$

**CKD-EPI Equation**

$GFR\ (mL/min/1.73\ m^2) = 141 \times \min(SCr/\kappa, 1)^{\alpha} \times \max(SCr/\kappa, 1)^{-1.209} \times 0.993^{age} \times (1.018 \text{ if female}) \times (1.159 \text{ if black})$

$\kappa = 0.7$ for females and 0.9 for males

$\alpha = -0.329$ for females and -0.411 for males

min indicates the minimum of $SCr/\kappa$ or 1

max indicates the maximum of $SCr/\kappa$ or 1

**Cystatin C**

Cystatin C is a protease which is completely filtered by the glomerulus and is not affected by muscle mass; it is not currently used in clinical practice, but may be a more accurate way to measure renal function in the future, particularly in DM

**Clinical Settings in which Urea Level is Affected Independent of Renal Function**

**Disproportionately High Urea**

- Volume depletion (prerenal azotemia)
- GI hemorrhage
- High protein diet
- Sepsis
- Catabolic state with tissue breakdown
- Corticosteroid or cytotoxic agents

**Disproportionately Low Urea**

- Low protein diet
- Liver disease

# Urinalysis

- use dipstick in freshly voided urine specimen to assess the following:

### 1. Specific Gravity
- ratio of the mass of equal volumes of urine/$H_2O$
- range is 1.001-1.030
- values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
- value usually 1.010 (isosthenuria: same specific gravity as plasma) in ESRD

**Estimating Urine Osmolality**
Last 2 digits of the specific gravity x 30 = urine osmolality approximately
(e.g. specific gravity of 1.020 = 600 mOsm)

### 2. pH
- urine pH is normally between 4.5-7.0; if persistently alkaline, consider
  - RTA
  - UTI with urease-producing bacteria (e.g. *Proteus*)

**24 h Urine Collection**
- Discard first morning specimen
- Collect all subsequent urine for the next 24 h
- Refrigerate between voids
- Collect second morning specimen and take to lab immediately

### 3. Glucose
- freely filtered at glomerulus and reabsorbed in proximal tubule
- causes of glycosuria include:
  1. hyperglycemia >9-11.1 mmol/L leads to filtration that exceeds tubular resorption capacity
  2. increased GFR (e.g. pregnancy - the proximal convoluted tubule is unable to reabsorb the glucose and amino acids)
  3. proximal tubule dysfunction (e.g. Fanconi's syndrome)
  4. sodium-glucose cotransporter 2 (SGLT2) inhibitors (also known as -flozin drugs) which are prescribed for DM2; lower the threshold for glucosuria by preventing glucose reabsorption from the filtrate

### 4. Protein
- dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
- microalbuminuria (morning ACR of 2.0 - 20 mg/mmol) is not detected by standard dipstick; greater than these ranges would be macroalbuminuria
- gold standard: 24 h timed urine collection for total protein

Positive dipstick for leukocyte esterase and nitrites is highly specific for diagnosing a UTI

### 5. Leukocyte Esterase
- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation along the urinary tract including prostate, bladder, ureter, pelvis and interstitium (e.g. AIN)

**Nitrite Negative Bacteria**
- *Enterococci*
- *Staphylococci*

### 6. Nitrites
- endogenous nitrates in urine are converted to nitrites by some bacteria (most commonly *E. coli*)
- high specificity but low sensitivity for UTI

**Nitrite Positive Bacteria**
- *Enterobacteriacae* (e.g. *E. coli*)

### 7. Ketones
- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

### 8. Hemoglobin
- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

# Urine Microscopy

**Table 2. Comparison of Urinary Sediment Findings**

| | Active Sediment = Suggestive of Parenchymal Kidney Disease | Bland Sediment = Less Likely Parenchymal Kidney Disease |
|---|---|---|
| **Any one or more of the following seen on microscopy** | Red cell casts | Only hyaline casts |
| | White cell casts | Small quantities of crystals |
| | Muddy-brown granular or epithelial cell casts | Small amount of bacteria |
| | >2 red cells per HPF | <2 red cells per HPF |
| | >4 white cells per HPF | <4 white cells per HPF |

### 1. CELLS

### Erythrocytes
- hematuria = >2 RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
- isomorphic RBCs, no casts suggest extraglomerular bleeding (e.g. bladder cancer)

### Leukocytes
- pyuria = greater than upper limit of normal: >4 WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, allergic cystitis, interstitial cystitis, papillary necrosis, renal tuberculosis, viral infections, *N. gonorrhoeae, C. trachomatis* infection

### Eosinophils
- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

### Oval Fat Bodies
- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

### 2. CASTS
- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

**Table 3. Interpretation of Casts**

| Casts | Interpretation |
|---|---|
| **Hyaline casts** | Physiologic (concentrated urine, fever, exercise) |
| **RBC casts** | Glomerular bleeding (Proliferative GN, vasculitis) |
| **WBC casts** | Infection (pyelonephritis)<br>Inflammation (interstitial nephritis) |
| **Pigmented granular casts (heme granular casts, muddy brown)** | ATN<br>Acute proliferative GN |
| **Fatty casts** | Nephrotic syndrome (>3.5 g/d) |

### 3. CRYSTALS
- uric acid: consider acidic urine, hyperuricosuria, tumour lysis syndrome
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning, nephrolithiasis
- sulfur: sulfa-containing antibiotics

## Urine Biochemistry

- commonly measure: $Na^+$, $K^+$, $Cl^-$, osmolality, and pH
- spot urine more useful to assess renal physiology, 24 h urine collection more reflective of mineral balance
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:

1. ECF volume depletion: expect low urine $[Na^+]$ (kidneys should be retaining $Na^+$)
   - urine $[Na^+]$ >20 mmol/L suggests a renal problem or the action of a diuretic
   - urine $[Na^+]$ <20 mmol/L suggests a prerenal problem
2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
   - if higher than 20 mmol/d, suggests renal contribution to hypokalemia

- osmolality is useful to estimate the kidney's concentrating ability
- $FE_{Na}$ refers to the fractional excretion of $Na^+$ (Na excreted in urine/Na filtered through kidney)
  - $FE_{Na}$ <1% suggests the pathology is prerenal
- urine pH is useful to grossly assess renal acidification
  - low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA Type 1)

**Fractional Excretion of Sodium**

$$FE_{Na} = \frac{[Na^+]_{urine} \times [Cr]_{plasma}}{[Na^+]_{plasma} \times [Cr]_{urine}} \times 100$$

# Electrolyte Disorders

## Sodium Homeostasis

- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the ECF relative to $Na^+$ content
  - hypernatremia usually suggests too little water in the ECF relative to $Na^+$ content
- solutes (such as $Na^+$, $K^+$, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by $Na^+$ content rather than concentration
  - $Na^+$ deficiency leads to ECF volume contraction
  - $Na^+$ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially brain cells) shrinking (hypernatremia) or swelling (hyponatremia)

**Table 4. Clinical Assessment of ECF Volume* (Total Body $Na^+$)**

| Fluid Compartment | Hypovolemic | Hypervolemic |
|---|---|---|
| **Intravascular** | | |
| JVP | Decreased | Increased |
| Blood pressure | Orthostatic drop | Normal to increased |
| Auscultation of heart | Tachycardia | S3 |
| Auscultation of lungs | Normal | Inspiratory crackles |
| **Interstitial** | | |
| Skin turgor | Decreased | Normal/increased |
| Edema (dependent) | Absent | Present |
| **Other** | | |
| Urine output | Decreased** | Variable |
| Body weight | Decreased | Increased |
| Hematocrit, serum protein | Increased | Decreased |
| Urine sodium | Increased | Decreased |

*Refers to effective circulating volume (ECV), which is the ECF volume adequately perfusing tissues.
**If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia

# Hyponatremia

- hyponatremia: serum [$Na^+$] <135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is associated with "appropriate" (hypovolemia) vs. "inappropriate" (euvolemia) ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

If the urine osmolality is unknown, assume the urine is hypo-osmolar/dilute

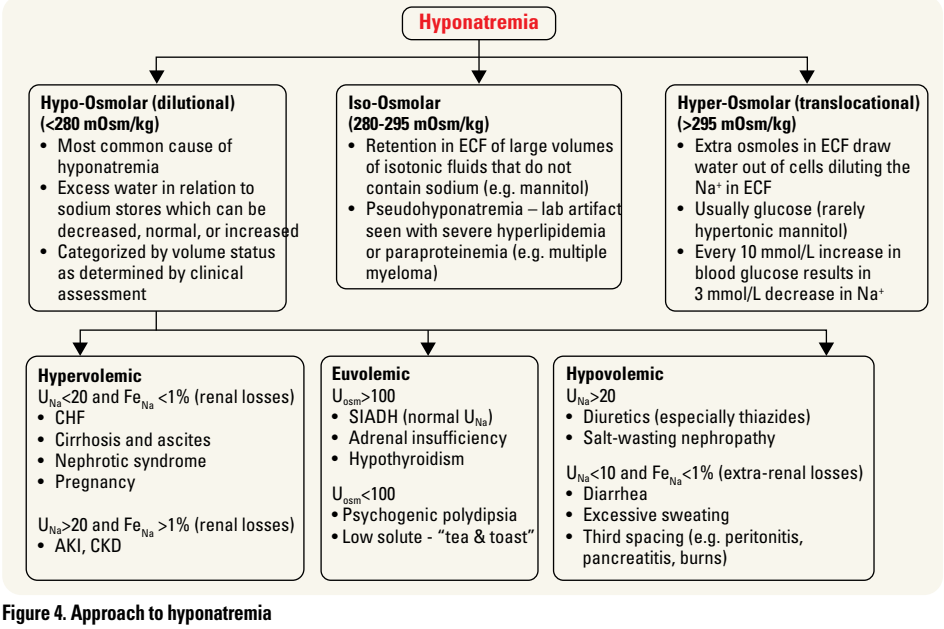

**Figure 4. Approach to hyponatremia**

## Signs and Symptoms

- depend on degree of hyponatremia and more importantly, velocity of progression from onset
- hyponatremia = swollen cells
- acute hyponatremia (<24-48 h) more likely to be symptomatic
- chronic hyponatremia (>24-48 h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

## Complications

- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis)
  - symptom onset may be delayed 2-6 d; begins as dysarthria, dysphagia, paresis, movement disorders → later on seizures, lethargy, confusion, disorientation, obtundation, coma

**Symptoms of Central Pontine Myelinolysis**
- Cranial nerve palsies
- Quadriplegia
- Decreased LOC

### Risk Factors for Osmotic Demyelination
- rise in serum [$Na^+$] with correction >8 mmol/L/24 h if chronic hyponatremia
- associated hypokalemia and/or malnutrition (e.g. low muscle mass)
- if patient with hyponatremia and hypovolemia is given large volume of isotonic fluid (ADH is stimulated by hypovolemia; when hypovolemia is corrected, the ADH level falls suddenly causing sudden brisk water diuresis, and therefore rapid rise in serum $Na^+$ level)
- patient with psychogenic polydipsia who is subsequently deprived of water

### Investigations
- ECF volume status assessment (see Table 4)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine Na+ (urine $Na^+$ <10-20 mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 5)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. paraneoplastic syndrome by small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH (i.e. subarachnoid hemorrhage)

### Treatment of Hyponatremia
- general measures for all patients
  1. treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
  2. restrict free water intake in SIADH (<1000 mL/d)
  3. promote free water loss
  4. carefully monitor serum Na+, urine volume, and urine tonicity
  5. monitor frequently that correction is not too rapid
- monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia as the stimulus for ADH is diminished with the correction of hypovolemia

**A. Known Acute (known to have developed over <24-48 h)**
- commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum [$Na^+$] = 125-130 mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on level of serum sodium
  - if serum [$Na^+$] >120 mmol/L, take general measures to identify and reverse cause of hyponatremia
  - if serum [$Na^+$] <120 mmol/L, treat as symptomatic
  - can consider giving 3% NaCl to prevent further deterioration in serum sodium
  - do not give 3% NaCl if hyponatremia is autocorrecting due to water diuresis

**B. Chronic or Unknown**
1. if severe symptoms (seizures or decreased LOC)
   - must partially correct acutely
   - aim for increase of $Na^+$ by 0.5-1 mmol/L/h for 4-6 h
   - limit total rise to 8 mmol/L in 24 h
   - IV 3% NaCl at 1-2 cc/kg/h
   - may need furosemide
2. if asymptomatic
   - water restrict to <1 L/d fluid intake
   - consider IV 0.9% NS + furosemide (reduces urine osmolality, augments excretion of $H_2O$)
   - consider NaCl tablet or Oxocubes® as a source of $Na^+$
3. refractory
   - furosemide and oral salt tablets
   - oral urea (osmotic aquaresis)
   - "vasopressin receptor 2 antagonists (e.g. tolvaptan)
4. always pay attention to patient's ECF volume status – if already volume-expanded, usually don`t give NaCl (tablet or IV); if already volume-depleted, almost never appropriate to give furosemide

**C. Options for Treatment of Overly-Rapid Correction**
- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2 µg IV)

### Impact of IV Solution on Serum [$Na^+$]
- formula to estimate the change in serum [$Na^+$] caused by retention of 1 L of any infusate

[TBW = (for men) 0.6 x weight(kg); (for women) 0.5 x weight(kg)]

$$\text{change in serum } [Na^+] = \frac{\text{infusate } [Na^+] - \text{serum } [Na^+]}{\text{TBW} + 1\text{ L}}$$

- formula assumes there are no losses of water or electrolytes

**Beware of Rapid Correction of Hyponatremia**
- Inadvertent rapid correction of hyponatremia can easily occur (e.g. patient with hyponatremia due to SIADH from nausea)
  - Anti-emetic given for relief of hyponatremia-induced nausea
  - ADH quickly turned off in the absence of nausea, the kidneys rapidly excrete the excess free water, and the serum [Na+] rises rapidly
- Patient at risk of osmotic demyelination
- High output dilute urine (>100 cc/h, <100 mOsm/L) in the setting of hyponatremia is usually the first sign of dangerously rapid correction of serum sodium

Correction of $Na^+$ in hyponatremia should not exceed 8 mmol/L/24 h unless definitely known to be <24-48 h duration; frequent monitoring of serum $Na^+$ and urine output is essential

**Concentration of [$Na^+$] in Common Infusates**
- [$Na^+$] in 0.45% NaCl = 77 mmol/L
- [$Na^+$] in 0.9% NaCl = 154 mmol/L
- [$Na^+$] in 3% NaCl = 513 mmol/L
- [$Na^+$] in 5% NaCl = 855 mmol/L
- [$Na^+$] in Ringer's lactate = 130 mmol/L
- [$Na^+$] in D5W = 0

## SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION

1. urine that is inappropriately concentrated for the serum osmolality
2. urine sodium >20-40 mmol/L – likely reflecting euvolemia
3. $FE_{Na}$ >1%

**Table 5. Disorders Associated with SIADH**

| Cancer | Pulmonary | CNS | Drugs | Miscellaneous |
|---|---|---|---|---|
| Small cell cancer<br>Bronchogenic carcinoma<br>Pancreatic adenocarcinoma<br>Hodgkin's lymphoma<br>Thymoma<br>Leukemia | Pneumonia<br>Lung abscess<br>Tuberculosis<br>Acute respiratory failure<br>Asthma<br>COPD<br>Positive pressure ventilation | Mass lesion<br>Encephalitis<br>Subarachnoid hemorrhage<br>Stroke<br>Head trauma<br>Acute psychosis<br>Acute intermittent porphyria | Antidepressants<br>TCAs<br>SSRIs<br>Antineoplastics<br>Vincristine<br>Cyclophosphamide<br>Anti-epileptics<br>Carbamazepine<br>Barbiturates<br>Chlorpropamide<br>ACEI<br>Other<br>DDAVP<br>Oxytocin<br>Nicotine | Post-operative state<br>Pain<br>Severe nausea<br>HIV |

# Hypernatremia

- hypernatremia: serum [$Na^+$] >145 mmol/L
- too little water relative to total body Na+; always a hyperosmolar state
- usually due to NET water loss or insufficient intake, rarely due to hypertonic $Na^+$ gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

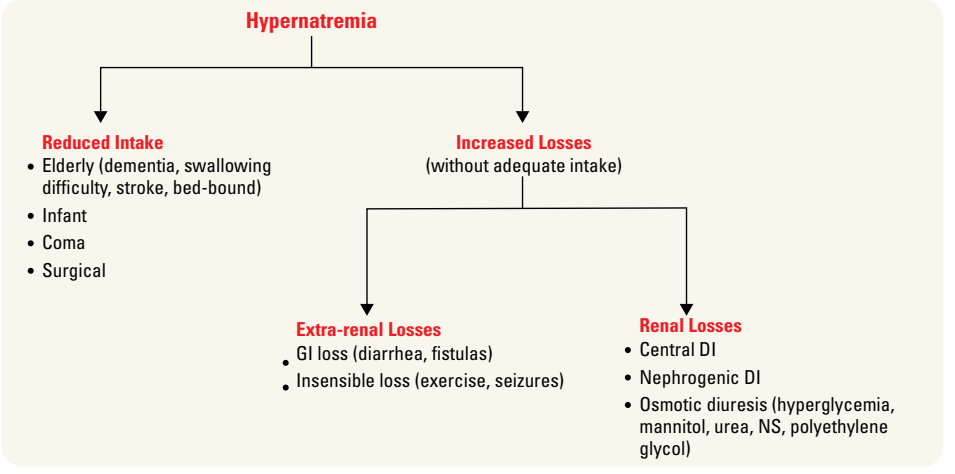

**Figure 5. Approach to hypernatremia**

### Signs and Symptoms

- hypernatremia = shrunken cells
  - acute hypernatremia (<24-48 h)
  - chronic hypernatremia (>24-48 h), cells will have achieved adaptive mechanism: can import and generate new osmotically active particles to normalize cell size
  - nearly all cases of hypernatremia will be due to chronic hypernatremia
  - acute hypernatremia primarily presents in patients with diabetes insipidus
  - symptoms due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

### Complications

- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema

### Treatment of Hypernatremia

- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum $Na^+$ frequently (q4h) to ensure correction is not occurring too rapidly

**$H_2O$ Deficit and TBW Equations**
TBW = 0.6 x wt (kg) men
TBW = 0.5 x wt (kg) women

$H_2O$ deficit = TBW x ([$Na^+$]plasma – 140) / 140

Correction of serum [$Na^+$] in hypernatremia should not exceed 12 mmol/L/24 h

1 L D5W approximately equals 1 L of free water
1 L 0.45% NS approximately equals 500 mL of free water

- if evidence of hemodynamic instability, then must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of $Na^+$, but a proportionately larger water loss
- encourage patient to drink pure water, as oral route is preferred for fluid administration
- if unable to replace PO or NG, correct $H_2O$ deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl ["2/3 and 1/3"])
- chronic hypernatremia – aim to lower serum sodium by 8-10 mEq/L in 24 h (often achieved by giving free water at 1.35 mL/kg/h)
- acute hypernatremia – use formula to calculate water deficit. Replace entire water deficit within 24 h (hourly infusion rate = water deficit in mL/24 h)
- infusion rate may need to be increased in order to account for ongoing losses in addition to initial deficit

# Diabetes Insipidus

- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

### Etiology
- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI
  - usually acquired – drugs (e.g. lithium), secondary to amyloidosis, sickle cell disease, Sjogren syndrome, polycystic kidney disease, electrolyte imbalances (i.e. hypercalcemia)
  - congenital/hereditary

### Diagnosis
- urine osmolality inappropriately low in patient with hypernatremia (Uosm <300 mOsm/kg)
- serum vasopressin concentration may be absent /low (central), or elevated (nephrogenic)
- dehydration test: $H_2O$ deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains <300 (fails to concentrate urine), most likely DI
- central DI: administer DDAVP (exogenous ADH) (10 μg intranasally or 2 μg SC or IV)
  - nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
- treat with water (IV D5W or PO water), thiazides may help as well (thiazides induce hypovolemia → stimulate proximal tubular reabsorption of sodium and water → less delivery of glomerular filtrate to the collecting duct → lower urine volume results)

# Potassium Homeostasis

- approximately 98% of total body $K^+$ stores are intracellular
- normal serum $K^+$ ranges from 3.5-5.0 mEq/L
- in response to $K^+$ rise, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia (K= >6.5 mEq/L)
- insulin, catecholamines, and acid-base status influence $K^+$ movement into cells
  - aldosterone has a minor effect
- potassium excretion is regulated at the distal tubule
  - $K^+$ excretion = urine flow rate x urine $[K^+]$

### Factors which Increase Renal $K^+$ Loss
- hyperkalemia
- increased distal tubular urine flow rate and $Na^+$ delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing $Na^+$ reabsorption and $K^+$ excretion
- metabolic alkalosis (increases $K^+$ secretion)
- hypomagnesemia
- increased non-reabsorbable anions in tubule lumen: $HCO_3^-$, penicillin, salicylate (increased tubular flow rate increases $K^+$ secretion)

# Hypokalemia

- serum $[K^+]$ <3.5 mEq/L

### Signs and Symptoms
- usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
- nausea/vomiting, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
- arrhythmias occur at variable levels of $K^+$; more likely if digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum $[K^+]$
  - U waves most important (low amplitude wave following a T wave)
  - flattened or inverted T waves
  - depressed ST segment
  - prolongation of Q-T interval
  - sinus bradycardia
  - with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity
  - common arrhythmias seen with hypokalemia: ventricular fibrillation, ventricular tachycardia

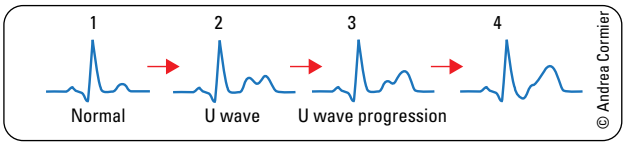

**Figure 6. ECG changes in hypokalemia**

## Approach to Hypokalemia

1. emergency measures if $K^+$ <2.5 mEq/L: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of $K^+$ as cause of hypokalemia
3. assess contribution of dietary $K^+$ intake
4. spot urine K:Cr (should be less than 1.5 mEq/mmol in setting of hypokalemia)
   - if <1.5 mEq/mmol consider GI loss
   - if >1.5 mEq/mmol consider a renal loss
5. consider 24 h $K^+$ excretion
6. if renal $K^+$ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum [$Mg^{2+}$]

- Hypokalemia often accompanied by metabolic alkalosis
- Potassium leaves cells, replaced by $H^+$
- Kidney tubular cells see high $H^+$, think acidosis, and increase ammonium synthesis and excretion
- Increase in bicarbonate generation

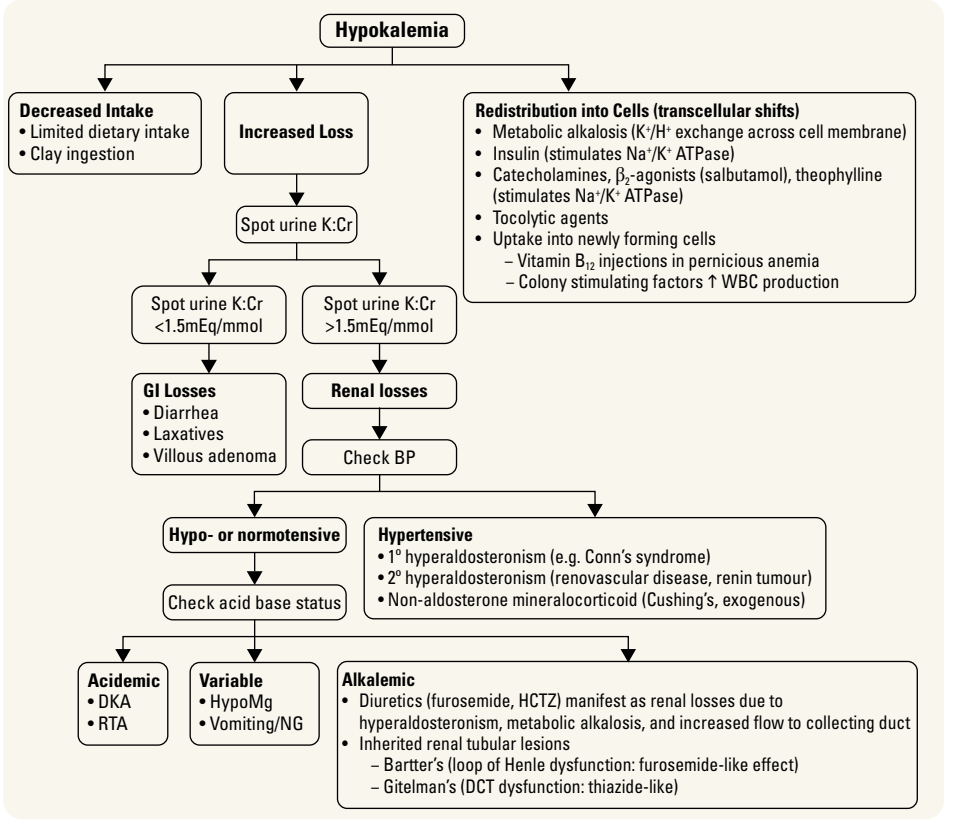

**Figure 7. Approach to hypokalemia**

## Treatment

- treat underlying cause
- if true $K^+$ deficit, potassium repletion
  - oral sources – food, tablets (K-Dur™), KCl liquid solutions (preferable route if the patient tolerates PO medications)
  - IV – usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
- max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
- $K^+$-sparing diuretics (triamterene, amiloride, spironolactone) can prevent renal $K^+$ loss
- restore $Mg^{2+}$ before correcting $K^+$
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- use ACE inhibitor or ARB for CHF (reduces angiotensin II action and therefore reduces aldosterone production)
- beware of excessive potassium repletion, especially if transcellular shift caused hypokalemia

# Hyperkalemia

- serum [$K^+$] >5.0 mEq/L

## Signs and Symptoms

- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and metabolic acidosis
- ECG changes and cardiotoxicity (do not correlate well with serum [$K^+$])
- peaked and narrow T waves
- decreased amplitude and eventual loss of P waves
- prolonged PR interval
- widening of QRS and eventual merging with T wave (sine-wave pattern)
- AV block
- ventricular fibrillation, asystole

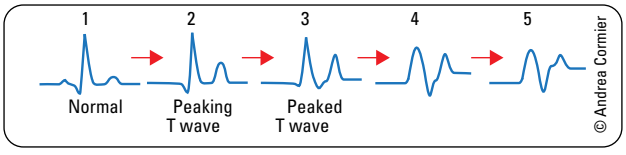

**Figure 8. ECG changes in hyperkalemia**

### Table 6. Causes of Hyperkalemia

| Factitious | Increased Intake | Transcellular Shift | Decreased Excretion |
|---|---|---|---|
| Sample hemolysis*<br>Sample taken from vein where IV KCl is running<br>Prolonged use of tourniquet<br>Leukocytosis (extreme)<br>Thrombocytosis** (extreme) | Diet<br>KCl tabs<br>IV KCl<br>Salt substitute | Intravascular hemolysis<br>Rhabdomyolysis<br>Tumour lysis syndrome<br>Insulin deficiency<br>Acidemia<br>Drugs<br>β-blockers<br>Digitalis overdose (blocks $Na^+/K^+$ ATPase)<br>Succinylcholine | Decreased GFR<br>Renal failure<br>Low effective circulating volume<br>NSAIDs in renal insufficiency<br>Normal GFR but hypoaldosteronism |

*Most common **Usually when blood specimen has been sitting out long before being analyzed

### Table 7. Causes of Hyperkalemia with Normal GFR

| Decreased Aldosterone Stimulus (low renin, low aldosterone) | Decreased Aldosterone Production (normal renin, low aldosterone) | Aldosterone Resistance (decreased tubular response) |
|---|---|---|
| Associated with diabetic nephropathy, NSAIDs, chronic interstitial nephritis, HIV | Adrenal insufficiency of any cause (e.g. Addison's disease, AIDS, metastatic cancer)<br>ACEI<br>Angiotensin II receptor blockers<br>Heparin<br>Congenital adrenal hyperplasia with 21-hydroxylase deficiency | $K^+$-sparing diuretics<br>Spironolactone<br>Amiloride<br>Triamterene<br>Renal tubulointerstitial disease |

## Approach to Hyperkalemia

1. emergency measures: obtain ECG, if life threatening begin treatment immediately
2. rule out factitious hyperkalemia; repeat blood test
3. hold exogenous $K^+$ (PO and IV) and any medications that are $K^+$ retaining (e.g. RAAS inhibitors (ACEI, ARBs), aldosterone antagonists, non-selective beta-blockers (propranolol/labetalol)) or affect $K^+$ excretion (i.e. NSAIDs)
4. assess potential causes of transcellular shift
5. estimate GFR (calculate CrCl using Cockcroft-Gault)

In patients with DM and increased [$K^+$] and hyperglycemia, often just giving insulin to restore euglycemia is sufficient to correct the hyperkalemia

## Treatment

- acute therapy is warranted if ECG changes are present or if patient is symptomatic regardless of [$K^+$]
- tailor therapy to severity of increase in [$K^+$] and ECG changes
  - [$K^+$] <6.5 and normal ECG
    - treat underlying cause, stop $K^+$ intake, increase the loss of $K^+$ via urine and/or GI tract
  - [$K^+$] between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - [$K^+$] >7.0 and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

**Treatment of Hyperkalemia**

**C BIG K DROP**
**C** – Calcium gluconate
**BIG** – β-agonist, Bicarbonate, Insulin, Glucose
**K** – Kayexalate®
**DROP** – Diuretics, Dialysis

### 1. Stabilize Myocardium

- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes the membrane action of hyperkalemia, protects cardiac conduction system, no effect on serum [$K^+$]
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)

**2. Shift $K^+$ into Cells**
- regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
  - onset of action 15-30 min, lasts 1-2 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat every 4-6 h
  - caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
- NaHCO3 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO3 in 1 L D5W)
  - onset of action 15-30 min, transient effect, drives $K^+$ into cells in exchange for H+
  - more effective if patient has metabolic acidosis
- β2-agonist (Ventolin®) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates $Na^+/K^+$ ATPase
  - caution if patient has heart disease as may result in tachycardia

**3. Enhance $K^+$ Removal from Body**
- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspecting aldosterone deficiency
- via GI (if renal function is severely impaired)
  - cation-exchange resins: calcium resonium or sodium polystyrene sulfonate (Kayexalate®) (which is prescribed in conjunction with sorbitol)
- Kayexalate® in combination with sorbitol should NOT be used as long-term therapy for chronic hyperkalemia as it is not very effective at lowering $K^+$ levels and may also lead to the development of colonic necrosis
- lactulose or sorbitol PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered - main benefit may be the diarrhea caused by lactulose)
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

**Management of Patients with Acute Hyperkalemia**
CMAJ 2010;182:1631-1635
**Purpose**: To review the evidence supporting different treatment options for acute hyperkalemia.
**Study**: Systematic review of updated research since 2005 Cochrane review, search 2003-2009 inclusive.
**Results**: Four new articles continued to support the acute usage of insulin and beta-agonists for shifting, and hemodialysis for elimination in severe and refractory hyperkalemia. One small randomized study comparing resins to laxatives was identified by the reviewers. It found no significant difference in serum potassium of the two groups in the 4 hours following administration. Study design was reportedly flawed; the resin group as a whole had lower initial serum concentration than the laxative control group.
**Conclusion**: Standard of care continues to include insulin, beta-agonists, and hemodialysis. There is no clear evidence supporting the use of resins, such as Kayexalate, for the acute management of hyperkalemia. Furthermore, prior studies have shown that resin usage can result in bowel obstruction and bowel necrosis.

# Hyperphosphatemia

## Definition
- serum phosphate >1.45 mmol/L
  - phosphate binds to serum calcium to create insoluble precipitates in soft tissues and blood vessels, thereby resulting in hypocalcemia
  - hypocalcemia subsequently triggers the development of secondary hyperparathyroidism in patients with advanced CKD on dialysis

## Etiology
- typically results from decreased renal excretion of phosphate

**Table 8. Etiology of Hyperphosphatemia**

| Increased Phosphate Load | Reduced Renal Clearance | Pseudohyperphosphatemia |
|---|---|---|
| GI intake (rectal enema, GI bleeding)<br>IV phosphate load (K-Phos®, blood transfusion)<br>Endogenous phosphate (tumour lysis syndrome, rhabdomyolysis, hemolysis, lactic and ketoacidosis) | Acute/chronic renal failure<br>Hypoparathyroidism<br>Acromegaly<br>Tumour calcinosis (ability of kidney to specifically clear phosphate is defective) | Hyperglobulinemia<br>Hyperlipidemia<br>Hyperbilirubinemia |

## Clinical Features
- non-specific, include ectopic calcification in soft tissues and vessels, renal osteodystrophy
  - symptoms consistent with hypocalcemia (e.g. tetany)

## Treatment
- acute: IV saline, hemodialysis if symptomatic;
- chronic: low $PO_4^{3-}$ diet, phosphate binders (e.g. $CaCO_3$ or lanthanum carbonate or sevelamer with meals)

# Hypophosphatemia

## Definition
- serum phosphate <0.80 mmol/L

## Etiology
- acute hypophosphatemia often caused by intracellular shifts of phosphate superimposed on chronic phosphate depletion
- chronic hypophosphatemia often caused by decreased renal phosphate reabsorption
- severe chronic hypophosphatemia often caused by chronic starvation or malabsorption (e.g. in patients with alcoholism) or chronic use of phosphate binders (e.g. patients with CKD)

Symptoms usually present when phosphate <0.32 mmol/L (1.0 mg/dL)
Treat asymptomatic patients if phosphate <0.32 mmol/L

Severe burns can cause hypophosphatemia due to $PO_4^{3-}$ losses through the skin

**Table 9. Etiology of Hypophosphatemia**

| Inadequate Intake | Renal Losses | Excessive Skeletal Mineralization | Shift into Intracellular Fluid |
|---|---|---|---|
| Starvation<br>Malabsorption (diarrhea, steatorrhea)<br>Antacid use<br>Alcoholism | Hyperparathyroidism<br>Diuretics<br>X-linked or autosomal dominant hypophosphatemic Rickets<br>Fanconi syndrome<br>Multiple myeloma<br>Early post-kidney transplant | Osteoblastic metastases<br>Post parathyroidectomy (referred to as 'hungry bone syndrome') | Recovery from metabolic acidosis<br>Respiratory alkalosis<br>Starvation refeeding (stimulated by insulin) |

### Clinical Features
- instability of cell membranes leading to hemolytic anemia or rhabdomyolysis
- MSK weakness, respiratory depression, low cardiac output/CHF from weakened cardiac muscles – symptoms arise due to low ATP production
- neurological symptoms: irritability, encephalopathy, seizures, coma
- hematologic symptoms: hemolytic anemia, decreased release of oxygen from hemoglobin, impaired leukocyte and platelet function (leading to worsening infections/defective clotting)

### Treatment
- initiate when serum [$PO_4^{3-}$] <0.64 mmol/L and symptomatic, or <0.32 mmol/L if asymptomatic
- treat underlying cause
  - Oral $PO_4^{3-}$: 2-4 g/d divided bid-qid (start at 1 g/d to minimize diarrhea), encourage $PO_4^{3-}$ rich diet
  - IV $PO_4^{3-}$: only for severely symptomatic patients or inability to tolerate oral therapy

## Hypermagnesemia

### Definition
- serum magnesium >1.05 mmol/L

### Etiology
- AKI/CRF
- $Mg^{2+}$-containing antacids or enemas
- IV administration of large doses of $MgSO_4$ (e.g. see Obstetrics, *Preeclampsia* OB24)

### Clinical Features
- rarely symptomatic
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest, hypotension

### Treatment
- discontinue $Mg^{2+}$-containing products
- 10% calcium gluconate 10-20 mL IV ($Mg^{2+}$-antagonist) for acute reversal of magnesium toxicity
- hemodialysis if renal failure, consider peritoneal dialysis in setting of hemodynamic compromise

## Hypomagnesemia

You will be unable to correct hypokalemia or hypocalcemia without first supplementing magnesium if patient is hypomagnesemic

### Definition
- serum magnesium <0.70 mmol/L

### Etiology

| GI losses | Excess renal loss |
|---|---|
| Starvation/malabsorption | 2° hyperaldosteronism due to cirrhosis and CHF |
| Vomiting/diarrhea | Hyperglycemia |
| Alcoholism | Hypokalemia |
| Acute pancreatitis | Hypercalcemia |
| | Loop and thiazide-type diuretics |
| | Nephrotoxic medications |
| | Proton-pump inhibitors |
| | Early post-renal transplant |

### Clinical Features
- tremors, nausea and vomiting, lethargy/weakness, seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de Pointes

### Treatment
- treat underlying cause
- encourage increased dietary intake e.g. fruits
- oral $Mg^{2+}$ salts unless patient has seizures or other severe symptoms
- $Mg^{2+}$ IM/IV; cellular uptake of $Mg^{2+}$ is slow, therefore repletion requires sustained correction
- discontinue diuretics
  - in patients requiring diuretics, use a $K^+$-sparing diuretic to minimize magnesuria

# Acid-Base Disorders

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, and CNS function
- see Respirology, R6 for more information on respiratory acidosis/alkalosis
- normal concentration of $HCO_3^-$ = 24 mEq/L (range: 22-30 mEq/L)
- normal $pCO_2$ = 40 mmHg (range: 36-44 mmHg)
- each acid-base disorder has an appropriate compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)

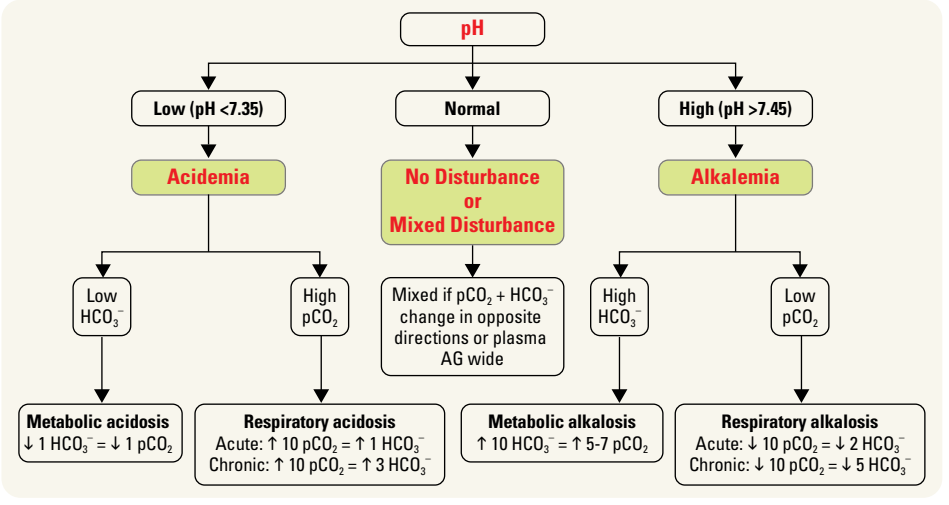

**Figure 9. Approach to acid-base disorders**

## Approach

**1. Identify the Primary Disturbance**
- respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

**2. Evaluate Compensation. If compensation is not appropriate, second acid-base disorder is likely present**
- compensation occurs in the same direction as the primary disturbance

**3. Calculate Plasma AG**
- AG = $[Na^+]$ – ($[HCO_3^-]$ + $[Cl^-]$)
- baseline = 12, normal range 10-14 mEq/L
- AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin] = 20 g/L, expect AG = 6 mEq/L)

**4. If AG elevated, compare increase in AG with decrease in $HCO_3^-$**
- if increase in AG < decrease in $HCO_3^-$, there is a coexisting non-AG metabolic acidosis
- if increase in AG > decrease in $HCO_3^-$, there is a coexisting metabolic alkalosis

**5. Calculate Osmolar Gap**
- osmolar gap = measured osmolality – calculated osmolality
  - calculated osmolality = (2 x $[Na^+]$) + [urea] + [glucose] (all units are in mmol/L)
  - normal osmolar gap <10
  - If OG >10, consider: methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

**Causes of Increased Osmolar Gap**
- Methanol
- Ethylene glycol
- Ethanol
- Polyethelene glycol
- Mannitol
- Sorbitol

**Useful Equations**
- AG = $[Na^+]$ - $[Cl^-]$ - $[HCO^{3-}]$ (normal range = 10-14 mEq/L)
- Osmolar Gap = measured serum osmolality – calculated osmolality (normal <10 mEq/L) – "Two Salts and a Sticky BUN"
- Calculated Osmolality = 2$[Na^+]$ + [Urea] + [Glucose] (+1.25[Ethanol])

# Metabolic Acidosis

## Etiology and Pathophysiology

**1. Increased AG Metabolic Acidosis (4 types)**

1. lactic acidosis (2 types)
   - L-lactic acid
     - type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
     - type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain anti-retrovirals, large tumours, mitochondrial myopathies
   - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
     - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility, and impaired D-lactate metabolism

**Causes of Increased AG Metabolic Acidosis**

**MUDPILES CAT**
**M**ethanol
**U**remia
**D**iabetic ketoacidosis
**P**araldehyde
**I**sopropyl alcohol/**I**ron/**I**buprofen/
**I**ndomethacin
**L**actic acidosis
**E**thylene glycol
**S**alicylates
**C**yanide and **C**arbon monoxide
**A**lcoholic ketoacidosis
**T**oluene

2. ketoacidosis
   - diabetic
   - starvation
   - alcoholic (decreased carbohydrate intake and vomiting)
3. toxins
   - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
   - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
   - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)
4. advanced renal failure (e.g. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)

**2. Normal AG Metabolic Acidosis (Hyperchloremic Acidosis) (involves increased bicarbonate excretion that is replaced with Cl)**
- diarrhea ($HCO_3^-$ loss from GI tract)
- RTA
  - type I RTA (distal): inability to secrete $H^+$ in collecting duct, leading to impaired excretion of ammonium into urine
  - type II RTA (proximal): impaired $HCO_3^-$ reabsorption
  - type III RTA: combination of Types I and II and is extremely rare
  - type IV RTA: defective ammoniagenesis due to decreased aldosterone, hyporesponsiveness to aldosterone, or hyperkalemia
- to help distinguish renal causes from non-renal causes, use Urine AG = $(Na^+ + K^+) - Cl^-$
- calculation establishes the presence or absence of unmeasured positive ions (e.g. $NH_4^+$) in urine
  - if UAG <0, suggests adequate $NH_4^+$ excretion in urine (likely nonrenal cause: diarrhea)
  - if UAG >0, suggests problem is lack of $NH_4^+$ in urine (e.g. distal RTA)

**Causes of Non-AG Metabolic Acidosis**
**HARDUP**
**H**yperalimentation
**A**cetazolamide
**R**TA*
**D**iarrhea*
**U**reteroenteric fistula
**P**ancreaticoduodenal fistula
*Most common

### Treatment of Metabolic Acidosis
1. treat underlying cause:
   - fluid resuscitation and insulin for DKA
   - restore tissue perfusion for Type A lactic acidosis
   - ethanol/fomepizole ± dialysis for methanol or ethylene glycol poisoning
   - alkaline diuresis ± dialysis if ASA overdose
2. correct coexisting disorders of $K^+$ (see *Hyperkalemia*, NP13)
3. consider treatment with exogenous alkali (e.g. $NaHCO_3$) if:
   - severe reduction in $[HCO_3^-]$ e.g. <8 mmol/L, especially with very low pH (<7)
   - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to $HCO_3^-$

- note: risks of sodium bicarbonate therapy
  - hypokalemia: causes $K^+$ to shift into cells (correct $K^+$ deficit first)
  - ECF volume overload: $Na^+$ load given with $NaHCO_3$, can exacerbate pulmonary edema
  - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to $HCO_3^-$, and persisting hyperventilation

**3 Clinical Scenarios that Produce a Mixed Disorder with Near Normal pH**
(e.g. increased AG metabolic acidosis + respiratory alkalosis)
- Cirrhosis
- ASA overdose
- Sepsis

# Metabolic Alkalosis

### Pathophysiology
- requires initiating event and maintenance factors
- precipitating factors
  - GI (vomiting, NG tube) or renal loss of $H^+$
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome
  - diuretics (contraction alkalosis): decreased excretion of $HCO_3^-$, decreased ECF volume, therefore increased $[HCO_3^-]$
  - post-hypercapnia: renal compensation for respiratory acidosis is $HCO_3^-$ retention, rapid correction of respiratory disorder results in transient excess of $HCO_3^-$
- maintenance factors
  - volume depletion: reduced GFR and increased proximal reabsorption of $NaHCO_3^-$ and increased aldosterone
  - hyperaldosteronism (1° or 2°): distal $Na^+$ reabsorption in exchange for $K^+$ and $H^+$ excretion leads to metabolic alkalosis; aldosterone also promotes hypokalemia
  - hypokalemia: transcellular $K^+/H^+$ exchange, stimulus for ammoniagenesis and $HCO_3^-$ generation

### Evaluate Compensation (identify co-existing respiratory acid-base disorders)
- hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

### Treatment
- treat underlying cause
- correct underlying disease, replenish $K^+$ and $Mg^{2+}$ deficits, and possibly $K^+$-sparing diuretic
- saline sensitive metabolic alkalosis (most common)
  - volume repletion ± carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of $HCO_3^-$ in urine
- saline resistant metabolic alkalosis
  - remove source of aldosterone or glucocorticoid ± spironolactone

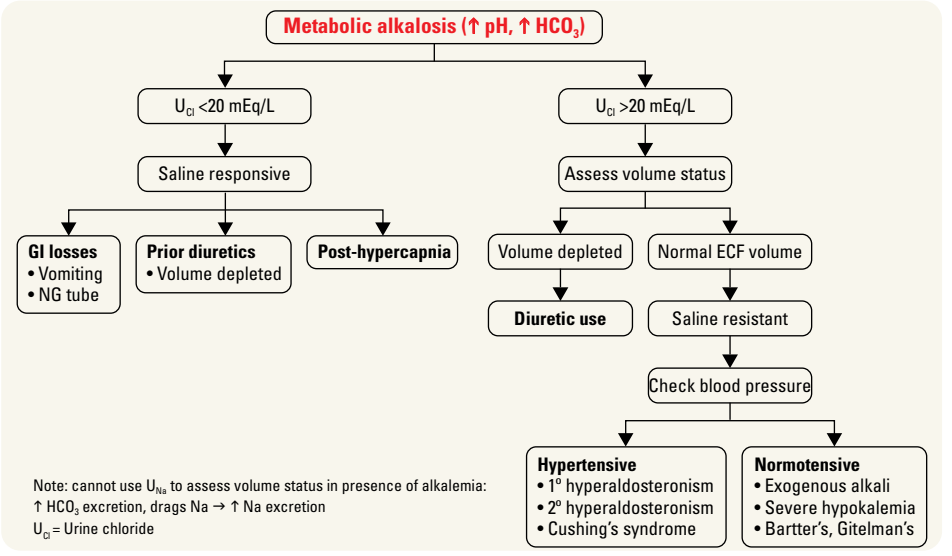

**Figure 10. Approach to metabolic alkalosis**

# Polyuria

## Definition
- output greater than 3 L/d. Distinguish from urinary frequency, where urination occurs multiple times per day but the total volume over 24 h is <3 L

## Etiology
- drugs (most commonly diuretics)
- excessive caffeine, alcohol intake
- increased water intake (psychogenic polydipsia, IV fluids)
- uncontrolled diabetes mellitus (osmotic diuresis)
- neurological: diabetes insipidus (central and peripheral), cerebral salt-wasting syndrome
- genitourinary: post-obstructive diuresis, cystitis/UTI

## Clinical Features
- must distinguish between true polyuria and urinary frequency
- look for sources of external fluid intake (IV fluids, tube feedings)
- assess for neurological changes (stroke, trauma, post-operative) (for central diabetes insipidus)
- assess for drugs that may cause nephrogenic diabetes insipidus (e.g. lithium)
- abrupt onset suggests central diabetes insipidus

## Investigation Findings
- hypernatremia suggests free water loss secondary to diabetes insipidus
  - hyponatremia suggests free water intake secondary to polydipsia
  - measure serum electrolyte/osmolality and urine osmolality after water deprivation test, see *Diabetes Insipidus*, NP11 for complete workup for diabetes insipidus

## Treatment
- addressed to etiology

# Acute Kidney Injury

## Definition
- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

The 2 most common causes of acute kidney injury in hospitalized patients are prerenal azotemia and ATN; remember that prerenal failure can lead to ATN

**Table 10. Classification of Acute Kidney Injury**

| CRITERIA | RIFLE | AKIN | KDIGO |
|---|---|---|---|
| **Serum Creatinine** | Increased 2-3 times baseline | Increase of ≥26.4 μmol/L or increase by >50%, within 48 h | Increase of ≥26.4 μmol/L within 48 h or increase by >50% within 7 d |
| **GFR** | Decreased >50% | N/A | N/A |
| **Urine Output** | <0.5 mL/kg/h for >12 h | <0.5 mL/kg/h for >6 h | <0.5 mL/kg/h for >6 h |

## Clinical Feature
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 ml/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

# Approach to AKI

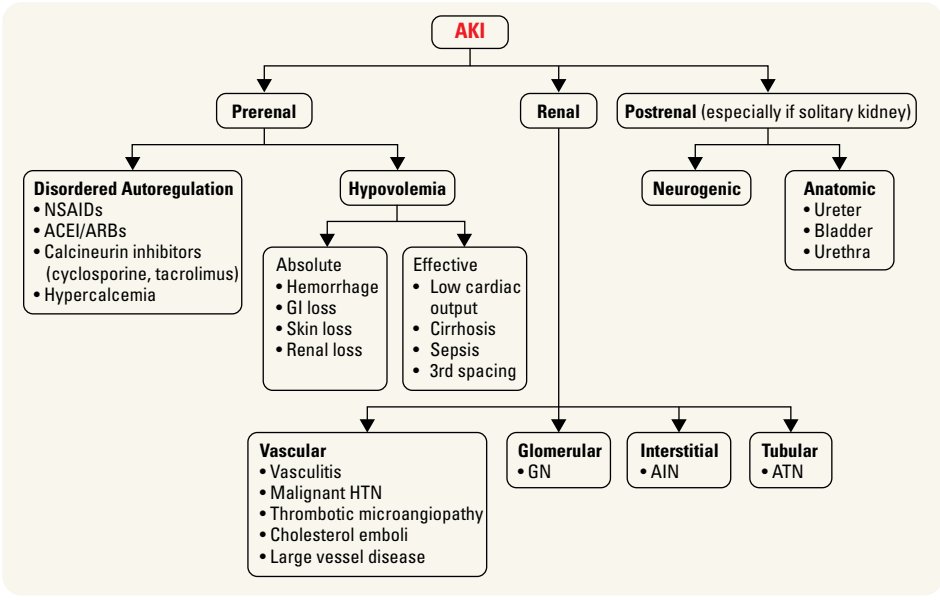

**Figure 11. Approach to AKI**

**Clues to Prerenal Etiology**
- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes
- Increased [urea] >> Increased [Cr]
- Urine [$Na^+$] <10-20 mmol/L
- Urine osmolality >500 mOsm/kg
- Fractional excretion of $Na^+$ <1%

**Clues to Renal Etiology**
- Appropriate clinical context
- Urinalysis positive for casts:
  Pigmented granular – ATN
  WBC – AIN
  RBC – GN
- Systemic features, anemia, thrombocytopenia, HTN, mild-moderate ECF volume overload

**Clues to Postrenal Etiology**
- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis

## Investigations
- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), $Ca^{2+}$, $PO_4^{3-}$
- urine dipstick: albumin, hemoglobin, WBC's, others: glucose, pH, urobilinogen, specific gravity
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- Foley catheterization (rule out bladder outlet obstruction)
- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >2-4 d
  - RPGN, signs of significant glomerular disease (proteinuria, RBC casts) despite normal kidney size/echogenicity

**Differentiating Prerenal from ATN**

| | Prerenal | ATN |
|---|---|---|
| Urinalysis | Normal | RBC, pigmented granular casts |
| Urine [$Na^+$] | <20 | >20 mEq/L |
| Urine[$Na^+$]/[Cr] | <20 | >20 |
| Urine osmolality | >500 | <350 mOsm/kg$H_2O$ |
| FeNa | <1% | >1% |

## Treatment
1. preliminary measures
   - prerenal
     - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF) and NSAIDs
   - renal
     - address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
     - correct ECF volume, supportive care, consider corticosteroid or immunosuppressive therapy
   - postrenal
     - consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
     - for obstruction to cause AKI, must have functional solitary kidney or obstruction affecting both kidneys
     - treat with Foley catheter insertion, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
   - fluid overload
     - NaCl restriction
     - high dose loop diuretics
     - hyperkalemia (see *Hyperkalemia*, NP13)
     - adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporin, tacrolimus, some antibiotics, and chemotherapeutic agents)
   - dialysis
3. definitive therapy depends on etiology

Avoid NSAIDs in patients with diarrhea, heart failure or renal failure

Renal transplant is not a therapy for AKI

**Drugs Implicated in Prerenal Azotemia**
- Diuretics
- NSAIDs
- ACEI/ARBs

## Prognosis
- high morbidity and mortality in patients with sustained AKI and multi-organ failure

# Parenchymal Kidney Diseases

## Glomerular Diseases

### HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

#### Extent of Changes

- histological term describing the number of glomeruli affected in a given condition:
  - diffuse: majority of glomeruli abnormal
  - focal: some glomeruli affected
- histological term describing the extent to which individual glomeruli are affected in a given condition
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

#### Types of Changes

- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
  - crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman's space
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane

### CLINICAL FEATURE OF GLOMERULAR DISEASE

#### Important Points to Remember

- glomerular diseases have diverse clinical features including hematuria, proteinuria, HTN, edema, and decreased GFR
  - each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
    1. asymptomatic urinary abnormalities
       - proteinuria
       - hematuria
    2. nephritic syndrome
       - acute GN
       - rapidly progressive GN
    3. nephrotic syndrome
    4. ESRD
- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

#### The Nephritic-Nephrotic Spectrum

- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes

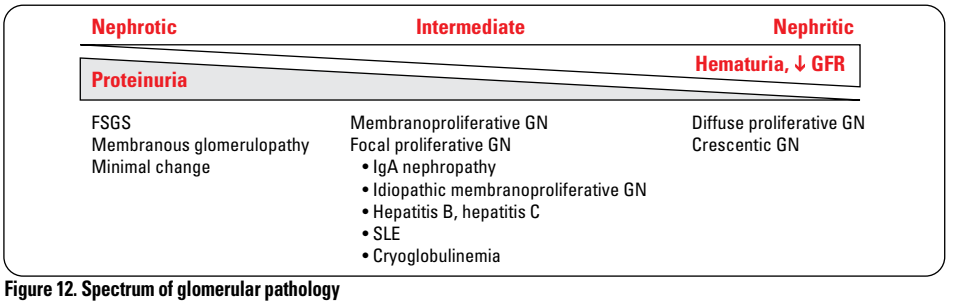

**Figure 12. Spectrum of glomerular pathology**

### PROTEINURIA

- hallmark of nephrotic syndromes
- composition of normal urine protein: albumin, lower molecular proteins (such as immunoglobulin light chain), or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)
- 24 h urine protein: gold standard to assess degree of proteinuria
- spot/random urine ACR: used to screen for diabetic nephropathy and proteinuric renal disease
- microalbuminuria: ACR ≥2.0 mg/mmol
  - marker of vascular endothelial function
  - an important prognostic marker for chronic kidney disease (see *Diabetes*, NP31)
  - microalbuminuria is the earliest sign of diabetic nephropathy
- composition of normal total urine protein
- upper limit of normal daily excretion of total protein is 150 mg/d
- upper limit of normal daily excretion of albumin is 30 mg/d
- the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin light chains or β-2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

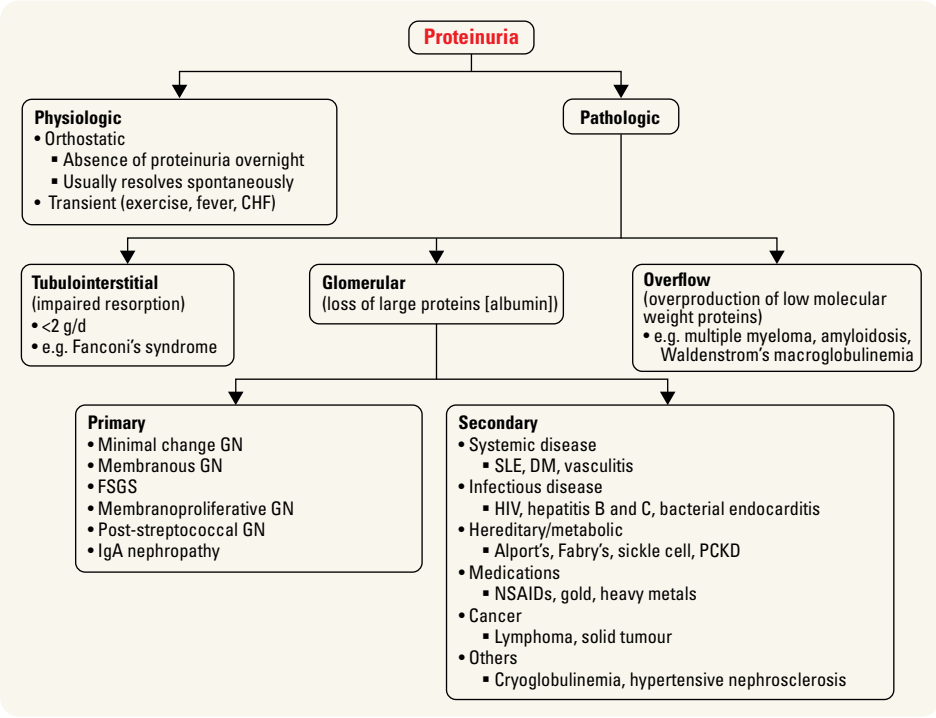

**Figure 13. Classification of proteinuria**

**Table 11. Daily Excretion of Protein**

| Daily Excretion | Stage of Nephropathy | ACR | PCR |
|---|---|---|---|
| <150 mg total protein (and <30 mg albumin) | Normal | <2.0 mg/mmol | <15 mg/mmol |
| 30-300 mg albumin | Microalbuminuria | >2.0 mg/mmol | |
| >3500 mg total protein/1.73m$^2$ body surface area | Nephrotic range proteinuria | >220 mg/mmol | >300 mg/mmol |
| Variable amount of proteinuria | Can be seen with glomerular disease | | |
| Up to 2000 mg per d | Possible tubular disease because of failure to reabsorb filtered proteins | | |

**Pathologic Proteinuria**

**Tubulointerstitial**
- Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
- Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins
- Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention

**Glomerular**
- Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus
- Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)

**Overflow**
- Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule
- Plasma cell dyscrasias produce light chain Ig (multiple myeloma, Waldenstrom's macroglobulinemia, monoclonal gammopathy of undetermined significance)

### Investigations
- urea, creatinine, ACR, PCR
- urine R&M, C&S
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  - CBC, glucose, electrolytes, 24 h urine protein, and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), C3, C4, Hep B, Hep C, HIV, ASOT
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age

# Glomerular Syndromes

## 1. ASYMPTOMATIC URINARY ABNORMALITIES

### Clinical/Lab Features
- often have rapid decline in GFR, anemia, elevated inflammatory markers, ECF volume replete or mildly overloaded
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  - isolated proteinuria
    - can be postural
    - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
  - hematuria with or without proteinuria
    - IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, frequently presents after viral upper respiratory tract infection
      - more common in Caucasian and Asian populations, and in the 2nd and 3rd decades of life
      - may be associated with cirrhosis, HIV infection, celiac disease
      - potential treatment includes: RAAS blockers if proteinuria, steroids, and steroid sparing agents (azathioprine, cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab)

- hereditary nephritis (Alport Syndrome – Type IV collagen mutation): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
- thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
- benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

## 2. NEPHRITIC SYNDROME

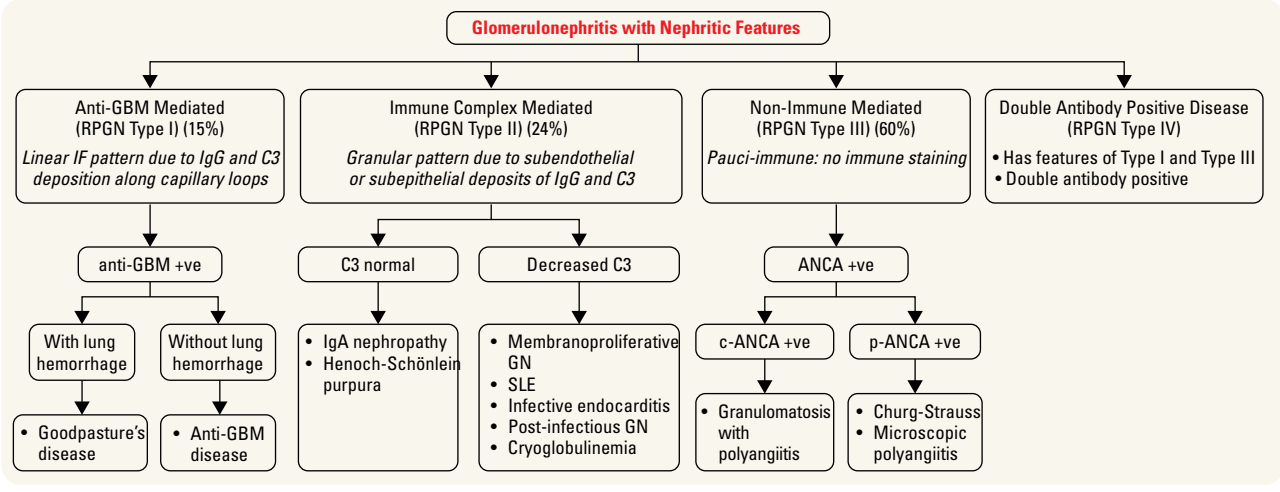

**Figure 14. Approach to nephritic syndrome**

### ACUTE NEPHRITIC SYNDROME

- a subset of nephritic syndrome in which the clinical course occurs over days
- etiology can be divided into low and normal complement levels
- frequently immune-mediated, with Ig and C3 deposits found in GBM; but may be pauci-immune and caused by an ANCA vasculitis

#### Clinical/Lab Features

- proteinuria (but <3.5 g/1.73 $m^2$/d)
- hematuria (microscopic or macroscopic)
- azotemia (increased Cr and urea)
- RBC casts and/or dysmorphic RBCs in urine
- HTN (due to salt and water retention)
- peripheral edema/puffy eyes

#### Treatment

- depends on etiology
- pulse steroid therapy and other immunosuppression (steroid sparing agents such as azathioprine and cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab), BP control (with RAAS agents, plasma exchange), monitoring for progression to end stage renal disease

**Interventions for Renal Vasculitis in Adults**
Cochrane DB Syst Rev 2015;CD003232
**Objective**: To assess benefits and harms of any intervention used for the treatment of renal vasculitis in adults.
**Methods**: RCTs in Cochrane Kidney and Transplant Specialized Register investigating any intervention for the treatment of renal vasculitis in adults.
**Conclusions**: Plasma exchange was effective in patients with severe AKI secondary to vasculitis. Pulse cyclophosphamide resulted in an increased risk of relapse (compared to continuous oral) but required reduced dose. Rituximab and mycophenolate mofetil were comparable in efficacy to cyclophosphamide. Azathioprine, methotrexate and leflunomide were effective as maintenance therapy.

### RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS

- a subset of nephritic syndrome in which the clinical course occurs over weeks to months
- clinical diagnosis, not histopathological
- any type of GN can present as RPGN (except minimal change disease)
- additional etiologies seen only as RPGN: anti-GBM disease and granulomatosis with polyangiitis (previously called Wegener's granulomatosis)
- crescentic GN (identified by pathology) is frequently seen in RPGN resulting from proliferation of parietal epithelial cells and is the most aggressive form of glomerular disease

#### Clinical/Lab Features

- fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- classified by immunofluorescence staining
- Type I: anti-GBM mediated (15% of cases)
- Type II: immune complex mediated (24% of cases)
- Type III: non-immune mediated (60% of cases)
- Type IV: double antibody positive

#### Treatment and Prognosis

- treatment: underlying cause for postinfectious; corticosteroids and cyclophosphamide or other cytotoxic agent and plasmapheresis in management of cases such as anti-GBM Ab
- prognosis: 50% recovery with early treatment, depends on underlying cause

## 3. NEPHROTIC SYNDROME

### Definition
- distinct constellation of clinical and laboratory features of renal disease defined by the presence of heavy proteinuria (protein excretion greater than 3.5 g/24 h), hypoalbuminemia (less than 3 g/dL), and peripheral edema

### Clinical/Lab Features
- heavy proteinuria (>3.5 g/1.73 $m^2$/d)
- hypoalbuminemia
- edema
- hyperlipidemia (elevated LDL cholesterol), lipiduria (fatty casts and oval fat bodies on microscopy)
- hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
- patient may report frothy urine
- glomerular pathology on renal biopsy (nephrotic syndrome is always caused by glomerular pathology)
- minimal change disease (or minimal lesion disease or nil disease) – e.g. glomeruli appear normal on light microscopy
  - membranous glomerulopathy
  - focal segmental glomerulosclerosis (FSGS)
  - membranoproliferative GN
  - nodular amyloidosis
- each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology; sirolimus rarely causes nephrotic syndrome)

**Table 12. Nephrotic Syndrome**

| | Minimal Change | Membranous Glomerulopathy | Focal Segmental Glomerulosclerosis | Membranoproliferative Glomerulonephritis | Nodular Glomerulosclerosis |
|---|---|---|---|---|---|
| **Secondary Causes** | Hodgkin's lymphoma | HBV, SLE, solid tumours (lung, breast, GI) | Reflux nephropathy, HIV, HBV, obesity, sickle cell disease | HCV, malaria, SLE, leukemia, lymphoma, shunt nephritis | DM, amyloidosis |
| **Drug Causes** | NSAIDs | Gold, penicillamine | Heroin | | |
| **Therapy** | Steroids | Reduce BP, ACEI, steroids | Steroids, ACEI/ARB for proteinuria | Aspirin®, ACEI, dipyridamole (Persantine®) – controversial | Treat underlying cause |

Note: the most common secondary causes are diabetes mellitus and amyloidosis

## INVESTIGATIONS FOR GLOMERULAR DISEASE
- blood work
  - first presentation: electrolytes, Cr, urea, albumin, fasting lipids, ACR
  - determining etiology: CBC, ESR, serum immunoelectrophoresis (for amyloidosis or multiple myeloma), C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV, anti-glomerular basement membrane antibodies (anti-GBM)
- urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- radiology
  - CXR (infiltrates, CHF, pleural effusion)
  - renal U/S
- renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- urine immunoelectrophoresis
  - for Bence-Jones protein if proteinuria present
- renal pathology (light microscopy, immunofluorescence, electron microscope)
- serum protein electrophoresis (SPEP)

## SECONDARY CAUSES OF GLOMERULAR DISEASE

### Amyloidosis
- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary
- secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy

### Lupus
- see Rheumatology, RH11
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement, ANA, anti-DNA levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

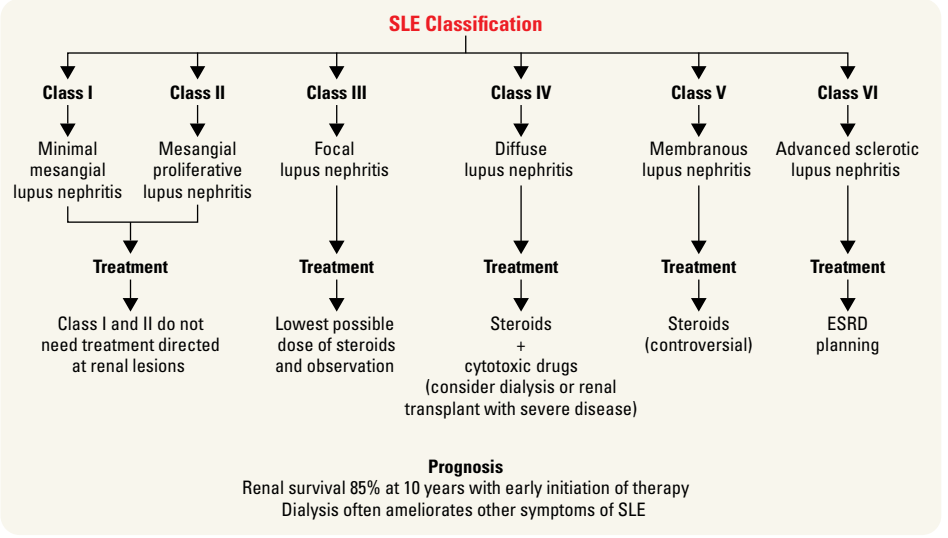

**Figure 15. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003**

## Henoch-Schönlein Purpura

- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

## ANCA-Associated Vasculitis

- c-ANCA most commonly associated with the clinical picture of granulomatosis with polyangiitis
- p-ANCA most commonly associated with the clinical picture of microscopic polyangiitis
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves cyclophosphamide and prednisone

## Cryoglobulinemia

- cryoglobulins: monoclonal IgM and polyclonal IgG which precipitate at reduced temperatures
- presents as purpura, fever, Raynaud's phenomenon, and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

## Shunt Nephritis

- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- commonly *S. epidermidis* is the cause
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
- treat by removing shunt and administering appropriate antibiotics; can consider a ventriculoperitoneal shunt

## HIV-Associated Renal Disease

1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
   - histology: focal and segmental glomerular collapse with mesangial sclerosis; "collapsing FSGS"
   - tubular cystic dilation and tubulo-reticular inclusions
   - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency (Apo-L-1 risk genotypes)
   - prognosis: kidney failure within 1 yr without treatment
   - therapy: short-term, high dose steroids, ACEI, HAART

**EULAR Recommendations for the Management of Systemic Lupus Erythematosus (SLE)**
Ann Rheum Dis 2008;67:195-205
**Lupus Nephritis Recommendations**
**Monitoring**: Renal biopsy, urine sediment analysis, proteinuria, and kidney function may have independent predictive ability for clinical outcome in therapy of lupus nephritis but need to be interpreted in conjunction. Changes in immunological tests (anti-dsDNA, serum C3) have limited ability to predict response to treatment and may be used only as supplemental information.
**Treatment**: In patients with proliferative lupus nephritis, glucocorticoids in combination with immunosuppressive agents are effective against progression to end-stage renal disease. Long-term efficacy has been demonstrated only for cyclophosphamide-based regimens, which are associated with considerable adverse effects. In short- and medium-term trials, mycophenolate mofetil has demonstrated at least similar efficacy compared with pulse cyclophosphamide and a more favourable toxicity profile. Failure to respond by 6 mo should evoke discussions for intensification of therapy. Flares following remission are not uncommon and require diligent follow-up.
**End-Stage Renal Disease**: Dialysis and transplantation in SLE have long-term patient and graft-survival rates comparable with those observed in non-diabetic non-SLE patients, with transplantation being the method of choice.

### Infective Endocarditis
- manifests as mild form of acute nephritic syndrome with decreased serum complement
- *S. aureus* is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

### Hepatitis B
- can result in membranous nephropathy, polyarteritis nodosa, membranoproliferative GN

### Hepatitis C
- can result in membranous nephropathy, cryoglobulinemia, and membranoproliferative GN

### Syphilis
- can result in membranous GN

### END STAGE RENAL DISEASE
- see *End Stage Renal Disease*, NP37

# Tubulointerstitial Disease

### TUBULOINTERSTITIAL NEPHRITIS

IgA nephropathy is the most common type of primary glomular disease worldwide

### Definition
- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

### Signs and Symptoms
- manifestation of disease depends on site of tubule affected

1. proximal tubule (e.g. multiple myeloma, heavy metals)
   - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hyperuricosuria
   - proximal RTA (decreased bicarbonate absorption): Type II RTA
2. distal tubule (e.g. amyloidosis, obstruction)
   - distal RTA (Type I RTA), usually hypokalemic
   - $Na^+$-wasting nephropathy
   - ± hyperkalemia leading to Type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
   - urinary concentrating defect leading to mild nephrogenic DI
   - polyuria

**Features of Nephritic Syndrome**

**PHAROH**
**P**roteinuria
**H**ematuria
**A**zotemia
**R**BC casts
**O**liguria
**H**TN

**Presentation of Nephrotic Syndrome**
**HELP**
**H**ypoalbuminemia
**E**dema
**L**ipid abnormalities
**P**roteinuria

### 1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

### Definition
- rapid (d to wk) decline in renal function
- 10-20% of all AKI

### Etiology
- hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins, fluoroquinolones
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
- infections
  - bacterial pyelonephritis, Streptococcus, brucellosis, Legionella, CMV, EBV, toxoplasmosis, leptospirosis, HIV, Mycoplasma
- immune
  - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
- idiopathic (renal-ocular syndrome – acute tubulointerstitial nephritis plus uveitis)

### Pathophysiology
- acute inflammatory cell infiltrates into renal interstitium

### Clinical Features
- AKI
- if hypersensitivity reaction (common with antibiotics): may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle (CVA) tenderness
- if drug reaction, AKI usually occurs 7-10 d after exposure
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon

### Findings
- urine
  - mild, non-nephrotic range proteinuria and microscopic hematuria
  - sterile pyuria, WBC casts
  - eosinophils if AIN
- blood work
  - increased Cr and urea
  - eosinophilia if drug reaction (high negative predictive value, common in β-lactam reactions)
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hypo- OR hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive – shows interstitial infiltrates and edema on biopsy

### Treatment
- treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

### Prognosis
- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely they will have a full renal recovery

## 2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

### Definition
- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

### Etiology
- persistence or progression of acute TIN
  - may also involve concurrent glomerular involvement
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
  - exogenous
    - analgesics: NSAIDs (common), acetaminophen
    - cisplatin, lithium, cyclosporine, tacrolimus
    - heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
    - Chinese herbs (aristolochic acid)
  - endogenous
    - hypercalcemia, hypokalemia, oxalate, uric acid
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, Sjögren's, cryoglobulinemia, anti-GBM disease, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

### Pathophysiology
- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

### Signs and Symptoms
- dependent on underlying etiology

### Findings
- normal AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi's syndrome
- progressive renal failure with azotemia and uremia
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours (differentiates acute from chronic etiology)

### Treatment
- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders ($Ca^{2+}$, $PO_4^{3-}$) and anemia

## 3. ACUTE TUBULAR NECROSIS

### Definition
- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

### Etiology

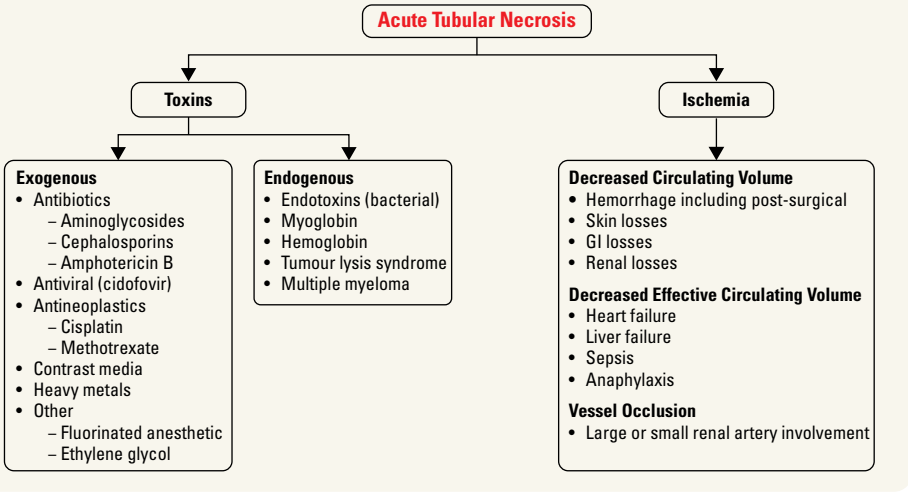

**Figure 16. Etiology of ATN**

**Effectiveness of Prevention Strategies for Contrast-Induced Nephropathy: A Systematic Review and Meta-Analysis**
Ann Intern Med 2016;164(6):406-16
**Objective**: To evaluate the comparative effectiveness of interventions to reduce contrast-induced nephropathy in adults receiving contrast media.
**Methods**: Meta-analysis of RCTs N-acetylcysteine, sodium bicarbonate, statins, or ascorbic acid that used IV or intra-arterial contrast media.
**Results**: Low dose N-acetylcysteine+IV saline vs. IV saline (RR 0.75, 95% CI 0.63-0.89). N-acetylcysteine+IV saline vs. IV saline (RR 0.69, 95% CI 0.58-0.84). Statins+N-acetylcysteine+IV saline vs. N-acetylcysteine+IV saline (RR 0.52, 95% CI 0.29-0.93). Clinically important, but not statistically significant, reductions were observed in sodium bicarbonate vs. IV saline, statins+IV saline vs. IV saline, and ascorbic acid vs. IV saline.
**Conclusions**: Greatest reduction in contrast-induced nephropathy was seen with N-acetylcysteine plus IV saline and statins plus N-acetylcysteine plus IV saline.

### Clinical Feature
- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
  - pre-renal AKI can eventually progress to ATN
  - usually asymptomatic, patient may experience oliguria in severe cases
- physical exam may show signs of true or effective ECF volume depletion
- most common cause of non-prerenal AKI in hospitalized patients
- urine: high $FE_{Na^+}$, pigmented-granular casts

### Risk Factors
- pre-existing chronic kidney disease, pre-existing cardiovascular disease, ECF volume depletion, multiple renal insults

### Complications
- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased $Ca^{2+}$, increased $PO_4^{3-}$, hypoalbuminemia

### Investigations
- blood work: CBC, electrolytes, Cr, urea, $Ca^{2+}$, $PO_4^{3-}$, blood gases
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
- ECG
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)
  - IV fluid challenge will not increase urine output or normalize serum creatinine in ATN, helps to differentiate ATN from pre-renal AKI
  - if diagnosis is uncertain, biopsy

### Treatment
- largely supportive once underlying problem is corrected
- consideration for early dialysis in severe/rapidly progressing cases to prevent uremic syndrome (the STARRT-AKI study addressing this is ongoing)

### Prevention
- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
  - isotonic saline
  - avoid giving diuretics, NSAIDS, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency
- use low dose non-ionic, iso- or low-osmolal contrast agents

# Vascular Diseases of the Kidney

## LARGE VESSEL DISEASE

**Table 13. Summary of Vascular Diseases**

| Large Vessel Disease | Medium Vessel Disease | Small Vessel Disease |
|---|---|---|
| Acute renal artery occlusion (infarct) | Kawasaki disease | Hypertensive nephrosclerosis |
| Renal artery stenosis (ischemia) | Polyarteritis nodosa | Atheroembolic renal disease |
| Renal vein thrombosis | | Thrombotic microangiopathy |
| | | Scleroderma |
| | | Calcineurin inhibitor nephropathy |
| | | Hemolytic Uremic Syndrome (HUS) |

## 1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)

- important, potentially reversible cause of renal failure

### Etiology

- abdominal trauma, surgery, embolism, vasculitis, extra-renal compression, hypercoagulable state, aortic dissection
- kidney transplant recipients more vulnerable

### Signs and Symptoms (depend on presence of collateral circulation)

- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

### Investigations

- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

### Treatment

- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

## 2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)

- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis
  - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
  - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
- when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
- most common cause of secondary HTN ("renovascular HTN"), 1-2% of all hypertensive patients
  - **etiology**
    - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
    - increased angiotensin raises blood pressure in two ways
      1. causes generalized arteriolar constriction
      2. release of aldosterone increases Na+ and water retention
  - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

### Risk Factors

- >50 yr
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

**Treatment of Hypertension in Association with Renovascular Disease**
Can J Cardiol 2017;33(5):557-76
**Guidelines:**
1. Recommend medical management as renal angioplasty and stenting offers no benefit over optimal medical therapy alone.
2. In patients with uncontrolled HTN resistant to maximally tolerated pharmacotherapy, progressive renal function loss and acute pulmonary edema, renal artery angioplasty and stenting for atherosclerotic hemodynamically significant stenosis could be considered.
Patients with confirmed renal fibromuscular dysplasia should be referred to HTN specialist and considered for revascularization.

### Signs and Symptoms
- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

### Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard)

### Treatment
- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late (e.g. kidney is already shrunken), however, therapy can be considered to save the opposite kidney if normal

## 3. RENAL VEIN THROMBOSIS

### Etiology
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical features determined by rapidity of occlusion and formation of collateral circulation

### Signs and Symptoms
- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

### Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

### Treatment
- thrombolytic therapy ± percutaneous thrombectomy for acute renal vein thrombosis
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

## MEDIUM VESSEL DISEASE

## 1. KAWASAKI DISEASE
- see Pediatrics, P88

## 2. POLYARTERITIS NODOSA
- see Rheumatology, RH20
- kidneys most commonly involved organ
- heterogenous impact on renal function
- pathologically can cause glomerular ischemia which manifests as mild proteinuria and hypertension

## SMALL VESSEL DISEASE

## 1. HYPERTENSIVE NEPHROSCLEROSIS
- see *Hypertension*, NP35

## 2. ATHEROEMBOLIC RENAL DISEASE
- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- **investigations**
  - eosinophilia, eosinophiluria, and hypocomplementemia
  - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels

**Stenting and Medical Therapy for Atherosclerotic Renal Artery Stenosis**
NEJM 2014;370:13-22
**Study**: Multicentre, unblinded RCT, median follow-up of 43 mo.
**Patients**: 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.
**Intervention**: Percutaneous revascularization (stenting) with medical therapy (statins, ARB, calcium channel blockers, HCTZ, and BP control) versus medical therapy alone.
**Outcomes**: Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.
**Results**: No significant difference in primary composite end point between participants who received stenting or those on medical therapy alone. No significant differences between the treatment groups in the rates of the individual components of the primary end point or in all-cause mortality.
**Conclusion**: Renal artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal artery stenosis and HTN or CKD.

- **treatment**
  - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- **prognosis**: poor overall, at least one third will develop ESRD

### 3. THROMBOTIC MICROANGIOPATHY
- see Hematology, H22
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia, drug-induced, complement mediated, metabolism-mediated, and coagulation-mediated
- the enzyme ADAMTS13 is reduced in TTP, and ADAMTS13 autoantibody are useful for diagnosing TTP
- events leading to HUS often begin with the ingestion of Shiga toxin-producing *E. coli*
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- **treatment**
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
- avoid platelet transfusions and ASA

### 4. CALCINEURIN INHIBITOR NEPHROPATHY
- secondary to the use of cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
  - prerenal azotemia
  - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

**Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation (ELITE-Symphony Trial)**
NEJM 2007;257:2562-2575
**Study**: Multicentre, RCT with 12 mo follow-up.
**Patients**: 1645 patients scheduled to receive a single organ kidney transplant.
Intervention: Mycophenolate mofetil, corticosteroids, and either: 1) standard dose cyclosporine; 2) low dose cyclosporine with daclizumab induction; 3) low dose tacrolimus with daclizumab induction; 4) low dose sirolimus with daclizumab induction.
**Primary Outcome**: Estimated Cockcroft-Gault GFR 12 mo after transplantation.
**Results**: The tacrolimus arm showed significantly higher eGFR at 12 mo compared to all other arms (65.4 mL/min vs. 57.1, 59.4, 56.7 for arms 1, 2, 4 respectively, $p \leq 0.001$). The tacrolimus arm also showed decreased rates of acute rejection at 6 mo and 12 mo vs. all arms ($p<0.001$), improved allograft survival against standard dose cyclosporine and sirolimus, and decreased treatment failure against all other arms. There was no difference in overall patient survival between groups. Sirolimus had the highest incidence of lymphoceles, delayed wound healing, and serious adverse events; tacrolimus had significantly higher rates of new-onset DM; and cyclosporine regimes had the lowest incidence of diarrhea but highest opportunistic infection rates.
**Conclusion**: Immunosuppression regiments using low dose tacrolimus and daclizumab induction decrease nephrotoxicity while maintaining therapeutic immunosuppression in renal transplant patients.

## Analgesic Nephropathies

### 1. Vasomotor AKI
- clinically: develop prerenal azotemia within a few days of starting NSAID
- normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
- NSAIDs act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
- more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
- treatment: discontinue NSAID, dialysis rarely needed

### 2. Acute Interstitial Nephritis
- fenoprofen (60%), ibuprofen, naproxen
- may be associated with minimal change glomerulopathy and nephrotic range proteinuria
- resolves eventually with discontinuation of NSAID, may require interval dialysis
- short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

### 3. Chronic Interstitial Nephritis
- due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
- seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
- papillary necrosis
  - gross hematuria, flank pain, declining renal function
  - calyceal filling defect seen with IVP – "ring sign"
- increased risk of transitional cell carcinoma of renal pelvis
- good prognosis if discontinue analgesics

### 4. Acute Tubular Necrosis
- can be caused by acetaminophen
  - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
- vascular endothelial damage can also occur
- both direct toxicity and ischemia contribute to the tubular damage
- renal function spontaneously returns to baseline within 1-4 wk
- dialysis may be required during the acute episode of ingestion

### 5. Other Effects of NSAIDs
- sodium retention (2° to reduced GFR)
- hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
- excess water retention (2° to loss of antagonistic effect of prostaglandins on ADH)

# Systemic Disease with Renal Manifestation

## Diabetes

- diabetic nephropathy: presence of microalbuminuria or overt nephropathy (e.g. macroalbuminuria, impaired GFR) in patients with DM who lack indicators of other renal diseases
- most common cause of end-stage renal failure in North America
- 50% of patients with diabetes will develop nephropathy
- greater burden in Indigenous communities
  - in Indigenous youth diagnosed with diabetes before age 20, risk of developing end-stage renal disease was 2.59 times higher compared to non-First Nations people with diabetes
  - 55.1% of First Nations individuals diagnosed with diabetes had chronic kidney disease
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
- indication of possible non-diabetic cause of renal disease in patients with DM
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of systemic disease
  - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
  - family history of non-diabetic renal disease (e.g. PCKD, Alport's)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD; the others are amyloidosis, HIV nephropathy, PCKD, and multiple myeloma

Abnormal Urine ACR Values from 2013 Canadian DM Association CPG
>2.0 mg/mmol in males and females

ACEI can cause hyperkalemia; therefore, be sure to watch serum $K^+$, especially if patient has DM and renal insufficiency

### DIABETIC RENAL COMPLICATIONS

#### 1. Progressive Glomerulosclerosis

- classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
- more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

**Table 14. Stages of Diabetic Progressive Glomerulosclerosis**

| | Stage 1 | Stage 2 | Stage 3 | Stage 4 |
|---|---|---|---|---|
| **Clinical** | ↑ GFR (120-150%) – compensatory hyperfiltration | Detectable microalbuminuria (0-300 mg/24 h)<br>(ACR) 2.0-20 mg/mmol (18-180 mg/d) | Macroalbuminuria (>300 mg/24 h)<br>ACR >20 mg/mmol, (>180 mg/d)<br>Proteinuria (positive urine dipstick)<br>Normal GFR | ↑ proteinuria (>500 mg/24 h)<br>↓ GFR |
| **Pathological** | ± slightly ↑ mesangial matrix | | ↑↑↑ mesangial matrix | Sclerosed glomeruli<br><20% glomerular filtration surface area present |

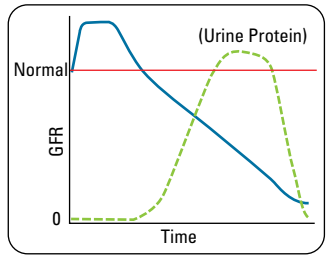

**Figure 17. GFR and urine protein over time in DM**

**Protein Restriction for Diabetic Renal Disease**
*Cochrane DB Syst Rev* 2007;4:CD002181
**Purpose**: To review the effects of dietary protein restriction on the progression of diabetic nephropathy.
**Study Selection**: RCTs and before and after studies of the effects of restricted protein diet on renal function in subjects with DM. 12 studies were reviewed.
**Results**: The risk of end-stage renal disease or death was lower in patients on low-protein diet. In patients with type 1 DM no effect on GFR was noted in the low-protein diet group.

#### 2. Accelerated Atherosclerosis

- common finding
- decreased GFR
- may increase angiotensin II production resulting in increased BP
- increased risk of ATN secondary to contrast media

#### 3. Autonomic Neuropathy

- causes atonic bladder, which leads to functional obstruction and urinary retention
- residual urine promotes infection
- obstructive nephropathy

#### 4. Papillary Necrosis

- type 1 DM susceptible to ischemic necrosis of medullary papillae
- sloughed papillae may obstruct ureter
- can present as renal colic or with obstructive features ± hydronephrosis

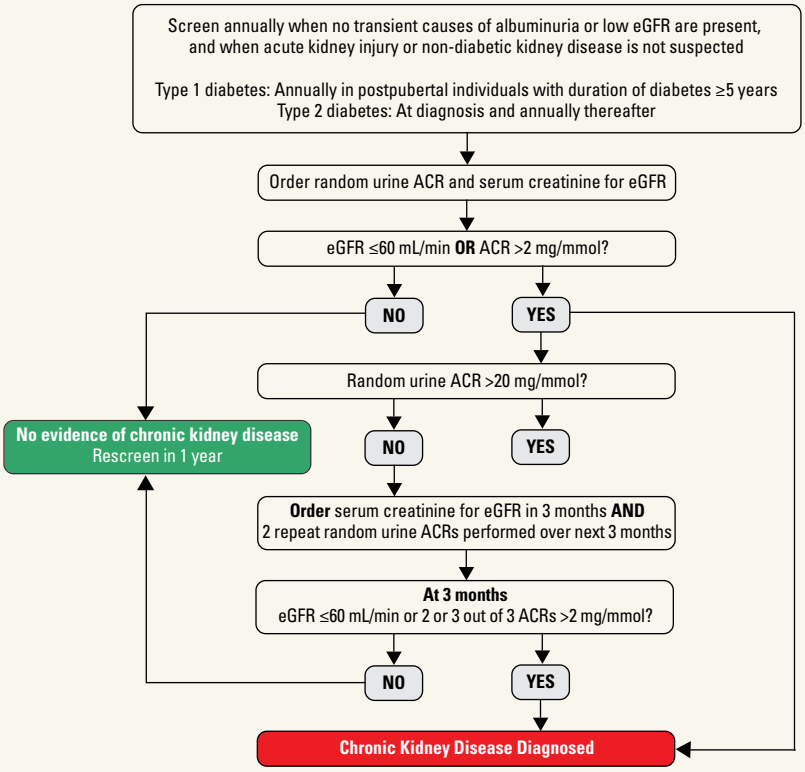

**Figure 18. Clinical practice guidelines on chronic kidney disease in diabetes**
Canadian Diabetes Association Clinical Practice Guidelines Expert Committee. Canadian Diabetes Association 2013 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada. Can J Diabetes 2013;37(suppl 1):S1-S212

**Renal Outcomes with Telmisartan, Ramipril, or Both in People at High Vascular Risk (ONTARGET Study)**
Lancet 2008;372:547-553
**Study**: Prospective, multicentre, double-blind, RCT.
**Participants**: 25,620 patients with median follow-up of 56 mo.
**Intervention**: Patients received either ramipril (10 mg/d; n=8576), telmisartan (80 mg/d; n=8542), or a combination of both drugs (n=8502).
**Primary Outcome**: Composite of dialysis, doubling of creatinine level, and death.
**Results**: The number of outcome events was similar for telmisartan (n=1147) and ramipril (1150; HR 1.00, 95% CI 0.92-1.09), but was increased with combination therapy (1233; HR 1.09, 1.01-1.18, p=0.037). The need for dialysis or doubling of serum creatinine, was similar with telmisartan (189) and ramipril (174; HR 1.09, 0.89-1.34) and more frequent with combination therapy (212; HR 1.24, 1.01-1.51, p=0.038). Estimated GFR declined least with ramipril compared with telmisartan or combination therapy (p<0.001). The increase in urinary albumin excretion was less with telmisartan (p=0.004) and combination therapy (p=0.001) than with ramipril.
**Conclusion**: Renal outcomes were similar in both telmisartan and ramipril monotherapy. Combination therapy reduced proteinuria to a greater extent than monotherapy, but was associated with poorer renal outcomes.

### Priorities in the Management of Patients with DM

1. vascular protection for all patients with DM
   - ACEI, antiplatelet therapy (as indicated)
   - BP control, glycemic control, lifestyle modification, lipid control
   - Canagliflozin provides renoprotection independent of its glycemic effects
2. optimization of BP in patients who are hypertensive
   - treat according to HTN guidelines
3. renal protection for DM patients with nephropathy (even in absence of HTN)
   - type 1 DM: ACEI or ARB
   - type 2 DM: CrCl >60 mL/min: ACEI or ARB; CrCl <60 mL/min: ARB
   - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
   - combination of ACEI and ARB not recommended
4. smoking cessation

- check serum Cr and $K^+$ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
- serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
- if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
- consider holding ACEI, ARB, and/or diuretic with acute illness and in women before becoming pregnant
- consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets, or unable to stay on ACEI or ARB

## Scleroderma

- see Rheumatology, RH13
- 50% of patients with scleroderma have renal involvement (mild proteinuria, high Cr, HTN)
- renal involvement usually occurs early in the course of illness
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% of scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- treatment: BP control with ACEI slows progression of renal disease

# Multiple Myeloma

- see Hematology, H49
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy or "myeloma kidney"
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease
  - diffuse tubular obstruction
- light chain cast nephropathy
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
  - proteinuria and renal insufficiency can progress rapidly to kidney failure
- monoclonal Ig deposition disease
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

# Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed unless malignancy is cured. Nephrology considerations for malignant presentations include:
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction, hyperkalemia, hyperphosphatemia, hypocalcemia, lactic acidosis
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/mets: postrenal failure secondary to obstruction
  - 2° amyloidosis
  - radiotherapy (radiation nephritis)

# Chronic Kidney Disease

## Definition

- progressive abnormalities of kidney function for >3 mo, with either
  - GFR <60 mL/min/1.73 $m^2$; or
  - markers of kidney damage, including:
  - hematuria, proteinuria, or anatomic abnormalities

## Clinical Features

- volume overload and HTN
- electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
- uremia (e.g. nausea/vomiting, pruritus, encephalopathy)
- anemia
- bone mineral disorders
- sleep disorders common in CKD: insomnia, sleep apnea, restless legs syndrome

**2016 CCS Guidelines for the Management of Dyslipidemia for the Prevention of CVD in the Adult – Chronic Kidney Disease**

Can J Cardiology 2016;32:1263-82

Recommendations:

- Adults ≥50 yr with CKD (GFR <60 mL/min/1.73$m^2$) should receive treatment with a statin or a statin/ezetimibe combination
- Initiation of lipid-lowering therapy is not recommended for adults with dialysis-dependent CKD however, if already receiving it at the time of dialysis initiation, it should be continued
- Statin therapy should be used in adults with kidney transplantation

**Incidence of Etiologies of CKD**

| | |
|---|---|
| DM | 42.9% |
| HTN | 26.4% |
| Glomerulonephritis | 9.9% |
| Other/Unknown | 7.7% |
| Interstitial nephritis/ Pyelonephritis | 4.0% |
| Cystic/Hereditary/Congenital | 3.1% |
| Secondary GN/Vasculitis | 2.4% |

**Management of Complications of CKD**

**NEPHRON**

- **N** – Low-nitrogen diet
- **E** – Electrolytes: monitor $K^+$
- **P** – pH: metabolic acidosis
- **H** – HTN
- **R** – RBCs: manage anemia with erythropoietin
- **O** – Osteodystrophy: give calcium between meals (to increase $Ca^{2+}$) and calcium with meals (to bind and decrease $PO_4^{3-}$)
- **N** – Nephrotoxins: avoid nephrotoxic drugs (ASA, gentamicin) and adjust doses of renally excreted medications

**Table 15. Stages of CKD (KDIGO, 2013)**

| | | | Persistent Albuminuria Categories | | |
|---|---|---|---|---|---|
| | | GFR (mL/min/1.73m²) | A1<br><30 mg/g<br><3 mg/mmol | A2<br>30-300 mg/g<br>3-30 mg/mmol | A3<br>>300 mg/g<br>>30 mg/mmol |
| **GFR Categories (mL/min/1.73m²)** | G1 | ≥90 | 1 if CKD | 1 | 2 |
| | G2 | 60-89 | 1 if CKD | 1 | 2 |
| | G3a | 45-59 | 1 | 2 | 3 |
| | G3b | 30-44 | 2 | 3 | 3 |
| | G4 | 15-29 | 3 | 3 | 4+ |
| | G5 | <15 (kidney failure) | 4+ | 4+ | 4+ |

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year
"D" is added to G5 for patients requiring dialysis
Classification is based on cause, GFR, and amount of albuminuria
Rate of progression and risk of complications are determined by the cause of CKD

# Management of Chronic Kidney Disease

- diet
  - preventing HTN and volume overload
  - low-protein diet
- $Na^+$ restriction
  - preventing electrolyte imbalances
  - target of <2 g/d (5 g/d of salt)
- $K^+$ restriction (40-60 mmol/d)
- $PO_4^{3-}$ restriction (1 g/d)
- avoid extra-dietary $Mg^{2+}$ (e.g. antacids)
  - preventing uremia and potentially delaying decline in GFR
- protein restriction with adequate caloric intake in order to limit endogenous protein catabolism
- medical
  - adjust dosages of renally excreted medications
  - HTN: ACEI (target 140/90 mmHg without DM and 130/80 mmHg with DM), loop diuretics when GFR <25 mL/min
  - dyslipidemia: statins (target LDL <2 mmol/L)
  - calcium and phosphate disorders
- consider vitamin D and calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic, but hold if hyperphosphatemic (reduces PTH)
- sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
- cinacalcet for hyperparathyroidism (sensitizes parathyroid to $Ca^{2+}$, decreasing PTH)
- metabolic acidosis: sodium bicarbonate
- anemia: erythropoietin injections for Hb <90 g/L (9 g/dL) and target Hb between 90-115g/L (9-10.5 g/dL). IV iron administration often required for iron deficiency
- clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
- dialysis (see NP38 for indications of dialysis in *Chronic Kidney Disease*)
- renal transplantation for end stage kidney disease

## Prevention of Progression

- as above
- control of HTN, DM (HbA1c <7%), cardiovascular risk factors (e.g. smoking cessation, physical activity, weight loss)
- avoid nephrotoxins such as NSAIDs, COXIBs, IV contrast in patients with eGFR <60 mL/min/1.73 $m^2$
- address reversible causes of AKI

**Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-Analysis**
Am Heart J 2008;155:791-805
**Purpose**: To evaluate the role of RAS blockade in improving cardiovascular CV outcomes in patients with CKD.
**Study Selection**: RCT that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB). RAS blockade-based therapy was compared with placebo and control therapy (β-blocker, calcium-channel blockers, and other antihypertensive-based therapy) in the study.
**Results**: Twenty-five trials (n=45,758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.
**Conclusions**: RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.

**Effects of Lowering LDL Cholesterol with Simvastatin and Ezetimibe in Patients with Chronic Kidney Disease**
Lancet 2011;377:2181-2192
**Purpose**: To assess the efficacy and safety of the combination of simvastatin and ezetimibe in patients with moderate to severe CKD.
**Study**: Randomized, double-blind trial with 9270 patients with CKD with no known history of myocardial infarction or coronary vascularization. Patients were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo.
**Primary Outcome**: First major atherosclerotic event (non-fatal myocardial infarction or coronary death, non-hemorrhagic stroke, or any arterial revascularization procedure).
**Results**: The simvastatin plus ezetimibe group was associated with an average LDL cholesterol difference of 0.85 mmol/L during a median follow-up of 4.9 yr. There was a 17% proportional reduction in major atherosclerotic events in the simvastatin plus ezetimibe group compared to placebo.
**Conclusions**: Reducing LDL cholesterol with a treatment regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with moderate to severe CKD.

**Effects of Intensive BP Control in CKD**
J Am Soc Nephrol 2017;28(9):2812-23
**Objective**: To evaluate appropriate target for BP in patients with CKD and HTN.
**Methods**: RCT subgroup analyses of participants in the Systolic Blood Pressure Intervention Trial (SPRINT). Participants were randomly assigned to intensive group (sBP <120 mmHg) or standard group (sBP <140 mmHg).
**Results**: The intensive group had a lower rate of all-cause death (HR 0.72, 95% CI 0.63-1.05) and major CV events (HR 0.81, 95% CI 0.63-1.05). Decreases in eGFR were comparable between treatment groups (HR 0.90, 95% CI 0.44-1.83). Treatment effects did not differ between participants with and without CKD.
**Conclusions**: In patients with CKD and HTN without diabetes, target sBP of 120 mmHg vs. 140 mmHg reduced rates of major CV events and all-cause death.

# Hypertension

- see Family Medicine, FM33
- HTN occurs in about 20% of population
- etiology classified as primary ("essential"; makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

## Hypertensive Nephrosclerosis

**Table 16. Chronic vs. Malignant Nephrosclerosis**

| | Chronic Nephrosclerosis | Malignant Nephrosclerosis |
|---|---|---|
| **Histology** | Slow vascular sclerosis with ischemic changes affecting intralobular and afferent arterioles | Fibrinoid necrosis of arterioles, disruption of vascular endothelium |
| **Clinical Picture** | Black race, underlying CKD, chronic hypertensive disease | Acute elevation in BP (dBP >120 mmHg)<br>HTN encephalopathy |
| **Urinalysis** | Mild proteinuria, normal urine sediment | Proteinuria and hematuria (RBC casts) |
| **Therapy** | Blood pressure control, (target <140/90) with frequent follow-up | Lower dBP to 100-110 mmHg within 6-24 h<br>More aggressive treatment can cause ischemic event<br>Identify and treat underlying cause of HTN |
| **Prognosis** | Can progress to renal failure despite patient adherence | Lower survival if renal insufficiency develops |

## Renovascular Hypertension

- see *Vascular Diseases of the Kidney*, NP28

## Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include:
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

### Investigations

- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of CrCl and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy (very rarely if at all)

### Treatment

- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: $Na^+$ restriction (2 g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor $K^+$ and Cr) if there is significant proteinuria (>300 mg/d)

# Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

## Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: *PKD1* (chr 16p) and *PKD2* (chr 4q)
- *PKD1* (1:400), *PKD2* (1:1000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant *PKD* gene but accumulate a series of second 'somatic hits' precipitating the condition
- *PKD* gene defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced GFR, salt-wasting with volume depletion, risk of calcium kidney stones)

- most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), cerebral aneurysm (10%), diverticulosis
- polycystic liver disease rarely causes liver failure, but may form the indication of liver transplant due to space occupying impact which can lead to reduced oral intake and malnutrition
- less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

### Signs and Symptoms
- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain
- hematuria (frequently initial sign is microscopic hematuria, otherwise gross hematuria)
- nocturia (urinary concentrating defect)
- extra-renal presentation (e.g. ruptured berry aneurysm, diverticulitis, mitral valve prolapse, aortic regurgitation, tricuspid valve prolapse)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

**Extra-Renal Manifestations of PCKD**
- Hepatic cysts
- Mitral valve prolapse
- Cerebral aneurysms
- Diverticulosis

### Common Complications
- urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

### Clinical Course
- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

**Tolvaptan in Later-Stage Autosomal Dominant Polycystic Kidney Disease**
NEJM 2017;377:1930-42
**Objectives**: To evaluate the efficacy and safety of the vasopressin V2-receptor antagonist tolvaptan in patients with later-stage autosomal dominant polycystic kidney disease.
**Methods**: Phase III, randomized withdrawal, multicentre, placebo-controlled, double-blind trial.
**Results**: Change in estimated GFR from baseline was -2.34 ml/min/1.732 in the tolvaptan group (95% CI, -2.81 to -1.87) vs. -3.61 ml/min/1.732 in the placebo group (95% CI, -4.08 to -3.14).
**Conclusions**: Tolvaptan resulted in a slower decline than placebo in the estimated GFR over a 1 yr period.

### Investigations
- radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- MRI for kidney volume measurement
- gene linkage analysis for PKD1 for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

### Treatment
- goal: to preserve renal function by prevention and treatment of complications
- tolvaptan has been used to slow decline of renal function, however its use has been limited by side effects
- educate patient and family about disease, its manifestations, and inheritance pattern
- genetic counselling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat HTN with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy for symptomatic relief of pain or due to recurrent infections

## Autosomal Recessive Polycystic Kidney Disease

- 1:20,000 incidence
- prenatal diagnosis by enlarged kidneys (due to cystic dilatation of the collecting ducts); if significant in utero can result in Potter sequence
- perinatal death from respiratory failure
- associated with hepatic fibrosis
- patients who survive perinatal period develop CHF, HTN, CKD, portal hypertension
- treated with dialysis, kidney and/or liver transplant

## Medullary Sponge Kidney

- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern ("bouquet of flowers"), "Swiss cheese" appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

# End Stage Renal Disease

- ESRD represents an irreversible decline in kidney function requiring renal replacement therapy
- no definite definition, but glomerular filtration rate less than 15 mL per minute per 1.73 $m^2$ body surface area, or those requiring dialysis irrespective of glomerular filtration rate

## Presentation of End Stage Renal Disease

### 1. Volume Overload
- due to increase in total body $Na^+$ content
- signs: weight gain, HTN, pulmonary or peripheral edema

### 2. Electrolyte Abnormalities
- high
  - $K^+$ (decreased renal excretion, increased tissue breakdown)
  - $PO_4^{3-}$ (decreased renal excretion, increased tissue breakdown)
  - $Ca^{2+}$ (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
  - uric acid
- low
  - $Na^+$ (failure to excrete excessive water intake)
  - $Ca^{2+}$ (decreased vitamin D activation, hyperphosphatemia, hypoalbuminemia)
  - $HCO_3^-$ (especially with sepsis or severe heart failure)

### 3. Uremic Syndrome
- manifestations result from retention of uremic toxins as well as hormone deficiencies

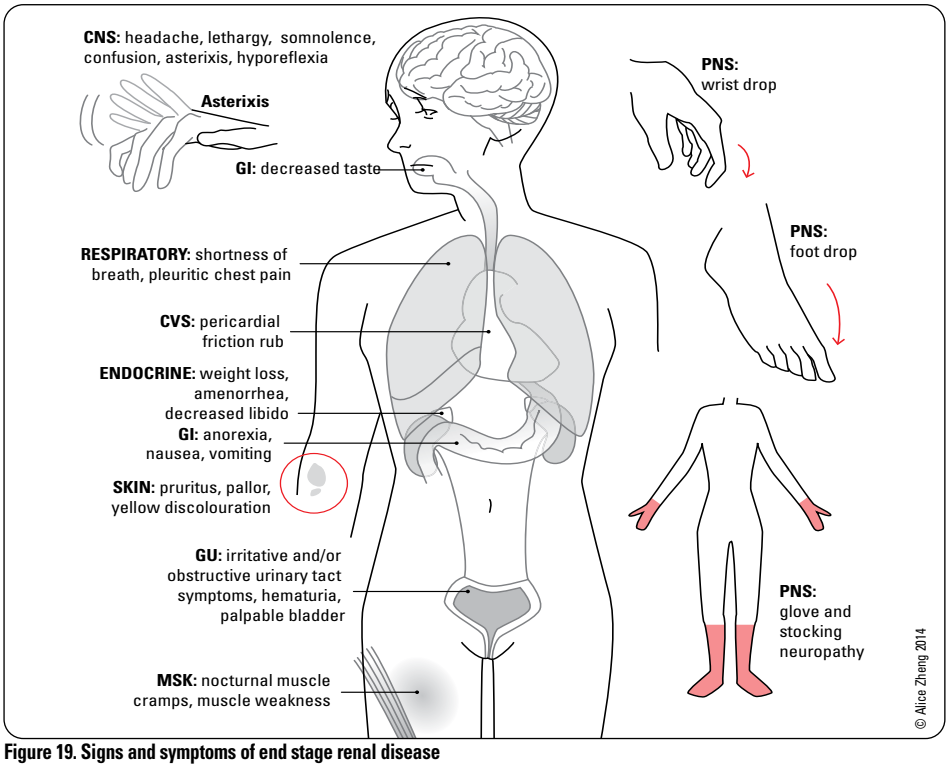

**Figure 19. Signs and symptoms of end stage renal disease**

### Complications
- CNS: decreased LOC, stupor, seizure
- CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine
  - decreased testosterone, estrogen, progesterone
  - increased FSH, LH
- metabolic
  - renal osteodystrophy: secondary increased PTH due to decreased $Ca^{2+}$, high $PO_4^{3-}$, and low active vitamin D
  - osteitis fibrosa cystica
  - hypertriglyceridemia, accelerated atherogenesis
  - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular $Ca^{2+}$ deposition)

# Renal Replacement Therapy

## Dialysis

### Indications for Dialysis in Chronic Kidney Disease

**Table 17. Indications for Dialysis**

| Absolute Indications | Relative Indications |
|---|---|
| Volume overload* | Anorexia |
| Hyperkalemia* | Decreased cognitive functioning |
| Severe metabolic acidosis* | Profound fatigue and weakness |
| Neurologic signs or symptoms of uremia (encephalopathy, neuropathy, seizures) | Severe anemia unresponsive to erythropoietin |
| Uremic pericarditis | Persistent severe pruritus |
| Refractory accelerated HTN | Restless leg syndrome |
| Clinically significant bleeding diathesis | |
| Persistent severe N/V | |

*Unresponsive to medications

- decision to start dialysis in ESRD should be symptom driven or when GFR reaches approximately 10 mL/min or lower
  - hemodialysis: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. 3-6x/wk), continuous (CVVHD) or sustained low efficiency (SLED) which are in-hospital treatments
  - can be delivered at home or in-centre, nocturnal
  - vascular access can be achieved through a central line, an artificial AV graft, or an AV fistula
- patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 μmol/L, or within 1 yr of an anticipated need
- check Kidney Failure Risk Equation, which provides the 2 and 5 year probability of treated kidney failure for a potential patient with CKD stage 3 to 5
- peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; 4-5 exchanges/d) or cyclic (CCPD; machine carries out exchanges overnight)
- refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

**Table 18. Peritoneal Dialysis vs. Hemodialysis**

| | Peritoneal Dialysis | Hemodialysis |
|---|---|---|
| **Rate** | Slow | Fast |
| **Location** | Home | Hospital (usually) |
| **Ultrafiltration** | Osmotic pressure via dextrose dialysate | Hydrostatic pressure |
| **Solute Removal** | Concentration gradient and convection | Concentration gradient and convection |
| **Membrane** | Peritoneum | Semi-permeable artificial membrane |
| **Method** | Indwelling catheter in peritoneal cavity | Line from vessel to artificial kidney |
| **Complications** | Infection at catheter site<br>Bacterial peritonitis<br>Metabolic effects of glucose<br>Difficult to achieve adequate clearance in patients with large body mass | Vascular access (clots, collapse)<br>Bacteremia<br>Bleeding due to heparin<br>Hemodynamic stress of extracorporeal circuit<br>Disequilibrium syndrome (headache, cerebral edema, hypotension, nausea, muscle cramps related to solute/water flux over short time) |
| **Preferred When** | Residual renal function<br>Success depends on presence of residual renal function<br>Hemodynamic instability | Comorbidities, no renal function<br>Residual renal function not as important<br>History of abdominal surgery |

## Renal Transplantation

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
  - best way to reverse uremic signs and symptoms
  - renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
- native kidneys usually left *in situ*

**How to Write Dialysis Orders (MUST BE INDIVIDUALIZED)**

- Filter Type (e.g. F80)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- $Na^+$ 140 (can be adjusted by starting at 155 and "ramping" down to minimize cramping)
- $K^+$ (based on serum $K^+$)

| Serum $K^+$ | Dialysate |
|---|---|
| 4-6 | 1.5 |
| 3.5-4 | 2.5 |
| <3.5 | 3.5 |

- $Ca^{2+}$ 1.25
- $HCO_3^-$ 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- IV fluid to support BP (e.g. NS)

**When to Initiate Dialysis**

CrCl <20 mL/min
- Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula

CrCl <15 mL/min
- Weigh risk and benefits for initiating dialysis

CrCl <10 mL/min
- Dialysis should be initiated

**NOTE**

- Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before CrCl <15 mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Source: National Kidney Foundation Kidney Disease Outcomes Quality Initiative

**Commonly Used Immunosuppressive Drugs**

**Calcineurin inhibitors**
- Cyclosporine
- Tacrolimus

**Antiproliferative medications**
- Mycophenolate mofetil
- Azathioprine

**Other agents**
- Sirolimus
- Prednisone

**Anti-lymphocyte antibodies**
- Thymoglobulin
- Basiliximab

**Indications for Dialysis (refractory to medical therapy)**

**AE IOU**
**A**cidosis
**E**lectrolyte imbalance ($K^+$)
**I**ntoxication (AKI)
**O**verload (fluid)
**U**remia (encephalopathy, pericarditis, urea >35-50 mM)

- 2 types: deceased donor, living donor (related or unrelated)
- living donor transplants have been shown to have better short- and long-term outcomes than deceased donor transplants
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- induction immunosuppression with IV thymoglobulin or basiliximab, followed by maintenance oral immunosuppression with an oral immunosuppression cocktail (usually corticosteroids, calcineurin inhibitor, anti-metabolite)
- long-term monitoring of cyclosporin and tacrolimus levels are required
- 1 yr renal allograft survival rates ≥90%

### Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- increased risk of infections (bacterial, viral, fungal, opportunistic)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection (cellular or humoral (antibody mediated))
- acute rejection: rise in Cr, fever, hematuria, graft site tenderness, oliguria, although symptoms are very uncommon
- early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
- transplant glomerulopathy from antibody injury
- cyclosporine or tacrolimus nephropathy (see *Small Vessel Disease*, NP29)
- de novo GN (membranous, IgA, MPGN)
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
- infections (CMV, PJP and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
- malignancy (skin cancer, Kaposi's sarcoma, non-Hodgkin's lymphoma)

**Survival Benefit with Kidney Transplants from HLA-Incompatible Live Donors**
NEJM 2016;374:940-950
**Purpose**: To assess whether there is a survival advantage to receiving a kidney from HLA-incompatible donors compared to remaining on the waiting list for a possible matched deceased donor kidney.
**Study**: Retrospective, multi-centre analysis
**Population**: 1025 individuals who received HLA-incompatible live donor kidneys compared to two different controls: individuals waiting and possibly receiving a deceased donor kidney (N=5125), or individuals ultimately not receiving a kidney transplant (N=5125).
**Outcome**: Survival, tracked for up to 8 years.
**Results**: Individuals who received HLA incompatible kidneys had increased survival compared to either control group for time points at 1 year, 5 years, and 8 years post-transplant ($p<0.001$). After 8 years non-matched kidney recipients had 76.5% survival compared to 43.9% for individuals who ultimately did not receive a kidney transplant. Survival advantage was significant regardless of how the recipient anti-HLA antibodies were detected.
**Conclusions**: Individuals who received HLA-incompatible kidneys had significantly improved long-term survival compared to individuals who waited for compatible deceased donor kidneys.

# Common Medications

**Table 19. Common Medications in Nephrology**

| Classification | Examples | Site of Action | Mechanism of Action (Secondary Effect) | Indication | Dosing | Adverse Effects |
|---|---|---|---|---|---|---|
| **Loop Diuretics** | furosemide (Lasix®)<br>bumetanide (Bumex®/Buinex®)<br>ethacrynate (Edecrin®)<br>torsemide (Demadex®) | Thick ascending limb of Loop of Henle | ↓ $Na^+/K^+/2Cl^-$ transport ± renal and peripheral vasodilatory effects ($K^+$ loss; ↑ $H^+$ secretion; ↑ $Ca^{2+}$ excretion) | Management of edema secondary to CHF, nephrotic syndrome, cirrhotic ascites;<br>↑ free water clearance (e.g. in SIADH-induced hyponatremia), ↓ BP (less effective due to short action) | furosemide:<br>edema: 20-80 mg IV/IM/PO q6-8h<br>(max 600 mg/d) until desired response<br>HTN: 20-80 mg/d PO OD/bid dosing | Allergy in sulfa-sensitive individuals<br>Electrolyte abnormalities; hypokalemia, hyponatremia, hypocalcemia, hypercalciuria (with stone formation)<br>Volume depletion with metabolic alkalosis<br>Precipitates gouty attacks |
| **Thiazide Diuretics** | hydrochlorothiazide (HCTZ)<br>chlorothiazide (Diuril®)<br>indapamide (Lozol®, Lozide®)<br>metolazone (Zaroxolyn®)<br>chlorthalidone (Hygroton®) | Distal convoluted tubule | Inhibit $Na^+/Cl^-$ transporter ($K^+$ loss; ↑ $H^+$ secretion; ↓ $Ca^{2+}$ excretion) | 1st line for essential HTN<br>Treatment of edema<br>Idiopathic hypercalciuria and stones<br>Diabetes insipidus (nephrogenic) | HCTZ:<br>edema: 25-100 mg PO OD<br>HTN: 12.5-25 mg PO OD<br>(max 50 mg/d)<br>nephrolithiasis/hypercalciuria: 25-100 mg OD | Hypokalemia<br>Increased serum urate levels<br>Precipitates gouty attacks, hypercalcemia<br>Elevated lipids<br>Glucose intolerance |
| **Potassium-Sparing Diuretics** | spironolactone (Aldactone®)<br>triamterene (Dyrenium®)<br>amiloride (Midamor®) | Cortical collecting duct (↓ $Na^+$ reabsorption) | Aldosterone antagonist (spironolactone)<br>Block $Na^+$ channels (triamterene and amiloride) | Reduces $K^+$ loss caused by other diuretics<br>Edema/hypervolemia<br>Severe CHF, ascites (spironolactone), cystic fibrosis (amiloride<br>↓ viscosity of secretions) | spironolactone: 25-200 mg/d OD/bid dosing<br>HTN: 50-200 mg/d OD/bid dosing<br>Hyperaldosteronism: 100-400 mg/d<br>OD/bid dosing<br>amiloride: edema/HTN: 5-10 mg PO OD | Hyperkalemia (caution with ACEI)<br>Triamterene can be nephrotoxic (rare)<br>Nephrolithiasis<br>Gynecomastia (estrogenic effect of spironolactone) |
| **Combination Agents** | Dyazide® (triamterene + HCTZ)<br>Aldactazide®<br>(spironolactone + HCTZ)<br>Moduretic® (amiloride + HCTZ)<br>Vaseretic® (enalapril + HCTZ)<br>Zestoretic® (lisinopril + HCTZ) | | Combination of ACEI and thiazide have a synergistic effect | Combine $K^+$-sparing drug with thiazide to reduce hypokalemia | | |
| **Osmotic Diuretics** | mannitol (Osmitrol®)<br>glycerol<br>urea | Renal tubules (proximal and collecting duct) | Non-reabsorbable solutes increase osmotic pressure of glomerular filtrate – inhibits reabsorption of water and ↑ urinary excretion of toxic materials | To ↓ intracranial or intraocular pressure<br>Mobilization of excess fluid in renal failure or edematous states | mannitol:<br>↓ ICP: 0.25-2 g/kg IV over 30-60 min | Transient volume expansion<br>Electrolyte abnormalities (↓/↑ $Na^+$, ↓/↑ $K^+$) |

**Table 19. Common Medications in Nephrology** (continued)

| Classification | Examples | Site of Action | Mechanism of Action (Secondary Effect) | Indication | Dosing | Adverse Effects |
|---|---|---|---|---|---|---|
| **ACEI** | ramipril (Altace®)<br>enalapril (Vasotec®)<br>lisinopril (Prinivil®)<br>trandolapril (Mavik®)<br>captopril (Capoten®) | Lungs<br>Tissues diffusely | Inhibits angiotension converting enzyme, preventing formation of angiotensin II<br>Prevents angiotensin II vasoconstricting vascular smooth muscle → net vasodilation → ↓ BP<br>Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules<br>→ ↑ $Na^+$ and $H_2O$ excretion → ↓ BP<br>Reduces fibrosis and atherogenesis | HTN<br>Cardioprotective effects<br>Renoprotective effects | ramipril: HTN: 2.5-20 mg PO OD/bid dosing<br>renoprotective use; 10 mg PO OD<br>trandolapril: HTN; 1-4 mg PO OD | Cough<br>Asthma<br>Hyperkalemia<br>Angioedema<br>Agranulocytosis (captopril)<br>AKI<br>Teratogenic |
| **ARB** | losartan (Cozaar®)<br>candesartan (Atacand®)<br>irbesartan (Avapro®)<br>valsartan (Diovan®)<br>telmisartan (Micardis®)<br>eprosartan (Teveten®)<br>olmesartan (Olmetec®) | Vascular smooth muscle, adrenal cortex, proximal tubules | Competitive inhibitor at the angiotensin II receptor: prevents angiotensin II vasoconstricting action on vascular smooth muscle → ↓ BP<br>Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules → ↑ $Na^+$ and $H_2O$ excretion | HTN<br>Cardioprotective effects<br>Renoprotective effects | HTN:<br>losartan 25-100 mg PO OD<br>candesartan 8-32 mg PO OD<br>irbesartan 150-300 mg PO OD<br>valsartan 80-320 mg PO OD<br>telmisartan 20-80 mg PO OD<br>eprosartan 400-800 mg PO OD<br>olmesartan 20-40 mg PO OD | Hyperkalemia<br>Caution – reduce dose in hepatic impairment<br>AKI<br>Teratogenic |
| **Renin Antagonists** | aliskiren (Rasilez®) | Direct renin antagonist | Inhibits renin production and activity<br>Cardioprotective and renoprotective abilities being evaluated | HTN | aliskiren 150-300 mg PO OD | Hyperkalemia |

# Landmark Nephrology Trials

| Trial | Reference | Results |
|---|---|---|
| 4D | NEJM 2005;353:238-48 | Patients with type 2 DM receiving maintenance hemodialysis were randomized to 20 mg of atorvastatin/d or matching placebo; no difference in composite index of death from cardiac causes, nonfatal myocardial infarction, and stroke |
| AASK | JAMA 2001;285:2719-28 | Ramipril, compared with amlodipine, slows progression of hypertensive renal disease and proteinuria and may benefit patients without proteinuria as well |
| ACCOMPLISH | NEJM 2008;359:2417-20 | Combination treatment with an ACEI and a CCB (benazepril-amlodipine) was more successful than a combination of ACEI and a thiazide diuretic (benzapril-HCTZ) in reducing cardiovascular events in patients with HTN who were at risk for such events |
| ACEI and Diabetic | NEJM 1993;329:1456-62 | Captopril protects against deterioration in renal function in insulin-dependent diabetic nephropathy and is significantly more effective than blood pressure control alone |
| ALERT | Lancet 2003;361:2024-31 | The use of fluvastatin in renal transplant recipients did not significantly decrease the risk of occurrence of a major adverse cardiac event (defined as cardiac death, non-fatal MI, or coronary intervention procedure) compared with placebo; however, there was a significant reduction in cardiac deaths or non-fatal MI |
| ALTITUDE | Early Termination (Unpublished Results;protocol – NDT 2009;24:1663-71) | Combining Aliskiren with ACEI or ARB in high-risk patients with type 2 DM leads to increased incidence of nonfatal stroke, hyperkalemia, and hypotension |
| ASTRAL | NEJM 2009;361:1953-62 | Renal artery revascularization compared to medical therapy does not improve renal function, BP, renal or cardiovascular events, or mortality, and carries significant operative risks |
| AURORA | NEJM 2009;360:1395-407 | Patients receiving maintenance hemodialysis randomized to rosuvastatin 10 mg daily or placebo; rosuvastatin lowered the LDL cholesterol level but had no significant effect on the composite primary end point of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke |
| BENEDICT | NEJM 2004;351:1941-51 | Treatment with ACEI trandolapril alone or trandolapril combined with verapamil decreased the incidence of microalbuminuria in patients with type 2 DM and HTN with normoalbuminuria |
| CHOIR | NEJM 2006;355:2085-98 | Patients with CKD were randomly assigned to receive a dose of epoetin alfa targeted to achieve a hemoglobin level of 135 g/L or 113 g/L; the higher target group had an increased risk of death, myocardial infarction, hospitalization for congestive heart failure (without renal replacement therapy), or stroke |
| CORAL | NEJM 2014;370:13-22 | Renal-artery stenting did not confer a significant benefit with respect to the prevention of renal or cardiac events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease |
| CREATE | NEJM 2006;355:2071-84 | Patients with CKD (15-35 mL/min) and mild to moderate anemia (110-125 g/L) were randomized to normal (130-150 g/L) or sub-normal (105-115 g/L) hemoglobin levels; early and complete correction of hemoglobin did not reduce the risk of cardiovascular events |
| DETAIL | NEJM 2004;351:1952-61 | The ARB telmisartan and the ACEI enalapril are equally effective in slowing renal function deterioration in type 2 DM with mild to moderate HTN and early nephropathy |

**Landmark Nephrology Trials** (continued)

| Trial | Reference | Results |
|---|---|---|
| ELITE-SYMPHONY | NEJM 2007;357:2562-75 | Daclizumab induction, MMF, steroids, and low-dose tacrolimus effectively maintain stable renal function following renal transplantation, without the negative effects on renal function commonly reported for standard CNI regimens |
| FHN | NEJM 2010;363:2287-300 | Patients were randomized to dialysis 6x/wk (frequent) or 3x/wk (conventional); frequent hemodialysis was associated with improvement in composite outcomes of death, or change in left ventricular mass and death, or change in a physical-health composite score; frequent hemodialysis caused more frequent interventions related to vascular access |
| HEMO | NEJM 2002;347:2010-19 | Use of high dose dialysis or high flux membranes versus standard dose or low flux in thrice-weekly dialysis does not improve survival or outcomes; possible benefit in cardiac-related outcomes with high flux membranes |
| IDEAL | NEJM 2010;363:609-19 | Patients with progressive CKD and GFR between 10 and 15 mL/min randomized to initiate dialysis at GFR of 10-14 mL/min (early) or 5-7 mL/min (late); early initiation of dialysis in patients with stage G5 CKD was not associated with an improvement in survival or clinical outcomes |
| IDNT | NEJM 2001;345:851-60 | Treatment with irbesartan reduced the risk of developing end-stage renal disease and worsening renal function in patients with type 2 DM and diabetic nephropathy |
| IRMA | NEJM 2001;345:870-8 | Irbesartan is renoprotective independently of its blood pressure lowering effect in patients with type 2 DM and microalbuminuria |
| MDRD | Ann Intern Med 1995;123:754-62 | Patients with proteinuria of more than 1 g/d should have a target BP <125/75 mmHg; patients with proteinuria of 0.25 to 1.0 g/d should have a target BP <130/80 mmHg |
| ONTARGET | Lancet 2008;372:547-53 | Telmisartan and ramipril monotherapy reduced proteinuria and rise in Cr in patients with high vascular risk; combination of the two agents led to increased acute renal failure episodes, syncope, and hypotension |
| REIN | Lancet 1999;354:359-64 | In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria |
| REIN2 | Lancet 2005;365:939-46 | In non-diabetic nephropathy already on ACEI, no further benefit from intensified BP control (sBP/dBP<130/80 mmHg) by adding a CCB versus conventional BP control (dBP<90 mmHg) on ACEI alone |
| RENAAL | NEJM 2001;345:861-9 | Losartan conferred significant renal benefits in patients with type 2 DM and nephropathy and was generally well-tolerated |
| RENAL | NEJM 2009;361:1627-38 | High intensity continuous renal-replacement therapy in AKI does not improve survival or outcomes compared to low intensity treatment, and is associated with higher rates of hypophosphatemia |
| Rituximab in Children with Steroid-Dependent Nephrotic Syndrome | JASN 2015;26 DOI: ASN.2014080799 | Rituximab is non-inferior to steroids in maintaining remission in juvenile steroid dependent nephrotic syndrome |
| ROAD | JASN 2007;18:1889-98 | Uptitration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency |
| ROADMAP | NEJM 2011;364:907-17 | The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with type 2 DM, normoalbuminuria, and good blood pressure control; however, a higher rate of fatal cardiovascular events was found amongst patients with preexisting coronary heart disease in the olmesartan group |
| SHARP | Lancet 2011;377:2181-92 | Randomized placebo-controlled trial in patients with CKD and no history of MI or coronary revascularization took simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo; simvastatin 20 mg plus ezetimibe 10 mg daily resulted in reduction of LDL cholesterol with associated reduction of major atherosclerotic events in patients with CKD |
| SPRINT | NEJM 2015;373:2103-2116 | A lower blood pressure target of 120/80 mmHg reduced the risk of composite cardiovascular events in a hypertensive patient population |
| TREAT | NEJM 2009;361:2019-32 | Patients with type 2 DM, CKD, and anemia were randomized to darbepoetin targeting a hemoglobin of 13 g/dL or placebo; darbepoetin did not reduce the risk of death, a cardiovascular event, or a renal event, and was associated with an increased risk of stroke |
| Tolvaptan in ADPKD | NEJM 2012;367: 2407-18 | Tolvaptan (vs. placebo) slowed the increase in total kidney volume and decline in kidney function over a 3-year period in patients with ADPKD but was associated with a higher discontinuation rate, due to adverse events |
| SGLT-2 inhibitor use and diabetic | J Am Soc Nephrol 2017; 28:368-375 | Canagliflozin, a sodium-glucose cotransporter 2 inhibitor, slowed the progression of renal disease over 2 years in patients with type 2 diabetes, and may confer renoprotective effects independently of glycemic control |

# Approach to the Neurological Complaint

## Lesion Localization

- **cortical**
  - contralateral paresis (with differential effect on face and arm vs. leg)
  - UMN injury (hyperreflexia, positive Babinski sign (extensor plantar response), spasticity, no muscle atrophy (early in the disease), pyramidal pattern of weakness (extensor muscle weakness in upper extremities and flexor muscle weakness is lower extremities)
  - cortical sensory loss (hemisensory loss, position sense, two-point discrimination, graphesthesia, stereognosis)
  - dominant hemisphere (aphasia, alexia, agraphia, acalculia, left-right disorientation)
  - non-dominant hemisphere (hemineglect, dysprosody, amusia, constructional apraxia, alien hand syndrome)
  - homonymous hemianopia/quadrantanopia
  - gaze deviation
  - seizure
  - agnosia (visual, auditory)
  - ideomotor and ideational apraxia
- **subcortical**
  - internal capsule: contralateral paresis with equal face, arm, leg involvement without sensory/cortical deficits; contralateral dysmetria/clumsiness and leg paresis
  - basal ganglia: pill-rolling tremor, bradykinesia, festinating gait, hemiballismus, chorea, dystonic posture
  - thalamus: dense sensory loss, contralateral severe pain, cognitive impairment, altered level of awareness
- **brainstem/bulbar (midbrain, pons, medulla)**
  - crossed hemiplegia or sensory loss (i.e. ipsilateral face, contralateral body)
  - ipsilateral ataxia (dysmetria, rapid alternating movements, tandem gait)
  - nystagmus with fast-beating component toward lesion, diplopia, INO (impaired adduction on contralateral gaze), pupillary abnormalities, gaze impairment
  - dysphagia, dysarthria
  - hearing loss, vertigo
  - hiccups
  - ipsilateral Horner's syndrome
- **cerebellum**
  - ipsilateral ataxia (unsteadiness, incoordination)
  - dysmetria, intention tremor
  - dysdiadochokinesia
  - wide-based gait, truncal titubation (staggering, reeling, lurching)
  - scanning speech (explosive speech with noticeable pauses and accentuated syllables)
  - nystagmus, distorted smooth pursuit, oscillopsia
  - pendular reflexes, hypotonia

- **spinal cord**
  - bilateral motor and/or sensory deficits below the lesion without facial involvement
  - sensory level (line below which there is decreased sensation); suspended "cape-like" sensory level (in central cord lesions)
  - LMN signs (flaccid paresis, hypotonia, hyporeflexia, atrophy, fasciculations) at level of lesion; UMN signs below lesion (marked spasticity, pyramidal distribution weakness and extensor plantar response)
  - bowel, bladder, sexual dysfunction
  - saddle anesthesia (i.e. cauda equina)
  - ataxia
- **nerve root**
  - multiple peripheral nerve involvement
  - myotomal/dermatomal deficits
  - back/neck pain radiating to leg/arm
- **peripheral nerve**
  - distal "stocking-glove distribution" sensory loss
  - weakness or sensory loss respecting the distribution of a specific nerve i.e. median nerve, ulnar nerve, radial nerve
  - LMN signs (hypotonia, hyporeflexia or areflexia, fasciculations, atrophy)
- **neuromuscular junction**
  - fluctuating/fatiguable symptoms
  - facial and limb weakness
  - dysphonia, dysarthria
  - ophthalmoparesis (diplopia), ptosis
  - reflexes usually preserved unless severe/advanced or LEMS
- **muscle**
  - usually symmetric proximal weakness (climbing stairs, getting up from chair) without sensory deficits
  - asymmetric myopathic weakness seen in distal myopathies, myositis, glycogen storage diseases, fascioscapulohymeral dystrophy
  - muscle tenderness
  - muscle atrophy

See Online Atlas for Cranial Nerves Exam, Motor Exam, and Sensory Exam Techniques

Battle's sign = mastoid ecchymosis
Raccoon eyes = periorbital ecchymosis

# The Neurological Exam

## General Exam and Mental Status

- **vitals:** pulse (especially rhythm), BP, RR, temperature
- **H&N:** meningismus, head injury/bruises (signs of basal skull fracture: Battle's sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
- **CVS:** carotid bruits, heart murmurs
- **mental status:** orientation (person, place, time), LOC (GCS) (see Emergency Medicine, ER4)
  - GCS/15 – Motor/6, Verbal/5 (T= intubated), Eyes/4

If patient has not brought their glasses, have them look through a pinhole for best corrected vision

When testing CN I, avoid noxious smells like ammonia, as this tests CN V

| Points | Eyes | Verbal | Motor |
|---|---|---|---|
| 1 | No eye opening | No verbal response | No motor response |
| 2 | Eye opening to pain | Incomprehensible sounds | Extension to pain |
| 3 | Eye opening to verbal stimulus | Inappropriate words | Flexion to pain |
| 4 | Eye opening spontaneously | Confused | Withdraws from pain |
| 5 | | Oriented | Localizes pain |
| 6 | | | Obeys commands |

- **cognition**
  - Folstein MMSE – /30 (normal: >23, mild impairment 19-23, moderate impairment: 10-18, severe impairment <10 note: dementia is a clinical diagnosis and is not diagnosed by cognitive testing)
  - MoCA – /30 (≥26 is considered normal)
  - frontal lobe testing (test for executive function – i.e. go/no-go test, Luria test, F-word list generation, trails test as well as frontal release signs i.e. grasp, pout-and-snout, rooting, palmomental, glabellar tap)
  - clock drawing

**Screening Neurologic Exam**

- Mental status: orientation (person, place, time), obeys commands, GCS
- Head and neck: examine for lacerations, contusions, deformities, signs of basal skull fracture, flex neck for meningismus if c-spine injury has been ruled out
- Cranial nerve exam: visual fields ± fundoscopy, pupil size and reactivity, extraocular movements, facial strength, hearing to finger rub
- Motor: tone, power in deltoids, triceps, wrist extensors, hand interossei, iliopsoas, hamstrings, ankle dorsiflexors, pronator drift
- Coordination: finger tapping, finger-to-nose, heel-knee-shin
- Gait: tandem gait, heel walking
- Reflexes: plantar, biceps, triceps, patellar, ankle, Babinski
- Sensation: all 4 limbs, including double simultaneous stimulation, vibration sense at great toes

# Cranial Nerve Exam

**Table 1. Cranial Nerve Examination and Associated Deficits**

| Cranial Nerve | Recommended Physical Exams | Signs/Symptoms of Deficit |
|---|---|---|
| **Olfactory (CN I)** | Odour sensation: test each nostril separately | Anosmia (can be associated with loss of taste) |
| **Optic (CN II)** | Visual acuity: test each eye individually; best corrected vision<br>Test visual fields: peripheral visual fields (counting fingers, white pin), central visual field and blind spot (red pin)<br>Assess pupils: direct and consensual pupillary reaction (afferent), swinging flashlight test (for RAPD)<br>Fundoscopy: optic disc edema and pallor, venous pulsations, hemorrhages<br>Colour vision testing (Ishihara plates) | Central vision loss<br>Peripheral vision loss<br>Absence of light reflexes, RAPD<br>Enlarged blind spot<br>Colour desaturation (especially red) |
| **Oculomotor (CN III)** | Assess extraocular movements and nystagmus<br>Test efferent limb of pupillary light response<br>Assess size and shape of pupils; accommodation reflex and saccadic eye movements<br>Test for ptosis (levator palpebrae superioris) | Eyes deviated down and out; ptosis, can demonstrate mydriasis |
| **Trochlear (CN IV)** | Test movement of superior oblique | Vertical diplopia; may tilt head towards unaffected side (Bielschowsky head tilt test); affected eye cannot turn inward and downward |
| **Trigeminal (CN V)** | Test sensation above supraorbital ridge (V1), maxilla or cheeks (V2), mandible (V3)<br>Test corneal reflex (afferent limb)<br>Assess motor function: temporalis, masseter, pterygoids, jaw jerk reflex | Ipsilateral facial dysesthesia and corneal reflex on stimulation ipsilaterally, weakness and wasting of muscles of mastication, deviation of open jaw to ipsilateral side; trigeminal neuralgia |
| **Abducens (CN VI)** | Test movement of lateral rectus | Horizontal diplopia, esotropia (convergent strabismus) and abductor paralysis of ipsilateral eye, leading to difficulty looking laterally with diplopia |
| **Facial (CN VII)** | Test sensorimotor nerve function with muscles of facial expression<br>Test efferent limb of corneal reflex<br>Visceral sensory nerve function to anterior 2/3 of the tongue<br>Visceral motor nerve function to salivary and lacrimal glands<br>Nerve to stapedius (dysfunction results in hyperacusis) | Paralysis of ipsilateral upper and lower facial muscles<br>Loss of lacrimation<br>Decreased salivation, dry mouth<br>Loss of taste to anterior 2/3 of the tongue ipsilaterally<br>LMN lesion = ipsilateral facial weakness<br>UMN lesion = contralateral facial weakness, sparing the eyebrow bilaterally |
| **Vestibulocochlear (CN VIII)** | Vestibular function - nystagmus, caloric reflexes<br>Cochlear function - whisper test, Rinne, Weber | Vertigo, disequilibrium, and nystagmus<br>Sensorineural hearing loss |
| **Glossopharyngeal (CN IX)** | Assess vocal cord function and gag reflex<br>Assess taste to posterior third of the tongue (bitter and sour taste) | Loss of taste in posterior third of ipsilateral tongue<br>Loss of gag reflex and dysphasia<br>Unilateral lesion is rare |
| **Vagus (CN X)** | Assess vocal cord function: guttural ("ga") and palatal ("ka") articulation<br>Assess gag reflex<br>Observe uvula deviation and palatal elevation<br>Assess swallowing | Loss of gag reflex, dysphagia, hoarse voice<br>Paralysis of soft palate (failed elevation)<br>Deviation of uvula to contralateral side of lesion; anesthesia of pharynx and larynx ipsilaterally |
| **Accessory (CN XI)** | Assess strength of trapezius (shoulder shrug) and sternocleidomastoid muscles (head turn) | Ipsilateral shoulder weakness and turning head to opposite side |
| **Hypoglossal (CN XII)** | Inspect tongue for signs of lateral deviation, atrophy, fasciculations, asymmetry of movement and strength | Wasting of ipsilateral tongue muscles and deviation to ipsilateral side on protrusion |

**CN Innervation of EOM**
LR: CN VI, SO: CN IV, Other: CN III

Contraction of the left sternocleidomastoid turns the head right

**Calorics: Brainstem Test**
Describe nystagmus by direction of fast component

**COWS**
**C**old
**O**pposite
**W**arm
**S**ame

**Upper Motor Neuron Tests**
**Babinski Reflex**: 'Up-going' big toe ± fanning of toes indicates an UMN lesion
**Hoffmann's Reflex**: Flexion of IP joint of the thumb when tapping/flicking/flexing the nail of the index or ring finger may indicate an UMN lesion if asymmetrical
**Pronator Drift**: Unable to maintain full arm extension and supination; side of forearm pronation reflects contralateral pyramidal tract lesion; closing eyes accentuates effect

**Pyramidal Pattern of Muscle Weakness (i.e. UMN)**
**Weaker arm extensors**: shoulder abduction, elbow extension, wrist extension, finger extension, finger abduction
**Weaker leg flexors**: hip flexion, knee flexion, ankle dorsiflexion

**Primitive Reflexes**
Grasp, palmomental, root, glabellar tap, snout

# Motor Exam

- bulk: atrophy, asymmetry
- tone: hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling
- power: pronator drift, asymmetric forearm rolling test (satellite sign)
- reflexes: deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski sign, Hoffmann sign, clonus
- abnormal movements: tremors, chorea, dystonia, dyskinesia, hemiballism, myoclonus, athetosis, tics, fasciculations, myokymia
- abnormal posturing: decorticate (upper extremity flexion, lower extremity extension), decerebrate (extremity extension)

**Table 2. Localization of Motor Deficits**

| | LMN | UMN | Extrapyramidal |
|---|---|---|---|
| **Muscle Tone** | Flaccid | Spastic | Rigid |
| **Involuntary Movements** | Fasciculations | None | None |
| **Reflexes** | Decreased | Increased | Normal |
| **Plantar Reflex** | Down-going (flexor) | Up-going (extensor, i.e. Babinski sign) | Down-going (flexor) |
| **Pattern of Muscle Weakness** | Proximal, distal, or focal | Pyramidal pattern: look for hemiparetic gait (flexed arm, extended legs)<br>Upper extremities: extensors weaker than flexors<br>Lower extremities: flexors weaker than extensors | None |

**Table 3. Overview of Neuromuscular Diseases**

| | Motor Neuron Disease (i.e. ALS) | Peripheral Neuropathy | Neuromuscular Junction | Myopathy |
|---|---|---|---|---|
| **SIGNS AND SYMPTOMS** | | | | |
| **Weakness** | Segmental and asymmetrical, distal to proximal | Distal (except GBS) but may be asymmetrical | Proximal and fatigable (e.g. MG), or weak then recovers (e.g. LEMS) | Proximal (with some exceptions) |
| **Fasciculations** | Yes | Yes | No | No |
| **Reflexes** | Combined hyperreflexia and decreased/absent reflexes | Decreased/absent | Normal | Normal (until late) |
| **Sensory** | No | Yes | No | No |
| **Autonomic*** | No | Yes | No | No |
| **TESTS** | | | | |
| **EMG** | Denervation and reinnervation | Signs of demyelination ± axonal loss | Decremental response, jitter on single fibre EMG | Small, short motor potentials |
| **NCS** | Normal | Abnormal | Normal | Normal |
| **Muscle Enzyme** | Normal | Normal | Normal | Increased (early/mid stage)<br>Normal/decreased (late stage) |

*e.g. orthostatic hypotension, anhidrosis, visual blurring, urinary hesitancy or incontinence, constipation, erectile dysfunction

**Table 4. Approach to Strength Testing of Radiculopathies vs. Peripheral Neuropathies**

How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerve. Particularly useful peripheral nerve "pairs" are bolded for emphasis.

| Root | Peripheral Nerve | Movement | Muscle |
|---|---|---|---|
| **C5** | Axillary | Shoulder abduction | Deltoid |
| **C6** | Musculocutaneous (C5/6)<br>Radial (C6) | Elbow flexion<br>Wrist extension | Biceps<br>Brachioradialis<br>Extensor carpi radialis longus |
| **C7** | Radial<br>Posterior interosseus | Elbow extension<br>Finger extension | Triceps<br>Extensor digitorum communis |
| **C8, T1** | **Median** | Thumb flexion<br>Thumb abduction<br>Opposition | Flexor pollicis brevis (look for thenar wasting)<br>Abductor pollicis brevis (look for thenar wasting)<br>Opponens pollicis (look for thenar wasting) |
| | **Ulnar** | Finger abduction | First dorsal interosseus (look for wasting in first dorsal webbed space) |
| **L2, 3, 4** | **Femoral**<br>**Obturator** | Hip flexion<br>Hip adduction | Iliopsoas<br>Adductor muscles |
| **L3, 4** | Femoral (L3/4)<br>Deep peroneal (L4/5) | Knee extension<br>Dorsiflexion | Quadriceps<br>Tibialis anterior |
| **L5** | Sciatic (L5, S1)<br>**Tibial**<br>**Superficial peroneal**<br>Deep peroneal | Hip extension<br>Ankle inversion<br>Ankle eversion<br>Big toe extension | Gluteus maximus<br>Tibialis posterior<br>Peroneal muscles<br>Extensor hallucis longus |
| **S1** | Sciatic<br>Tibial | Knee flexion<br>Plantar flexion | Hamstring muscles<br>Gastrocnemius and soleus |

# Sensory Exam

- **primary sensation**
  - spinothalamic tract: crude touch, pain, temperature
  - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
- **cortical sensation**
  - graphesthesia, stereognosis, extinction (tactile, visual, auditory), 2-point discrimination

Note: If primary sensation is not intact, this precludes the testing of cortical sensation. Deficits in cortical sensation are typically a sign of contralateral parietal lobe lesions

**MRC Muscle Strength Scale**
5 Full power
4 Submaximal power against resistance (ranging 4+, 4, 4-)
3 Full ROM against gravity without resistance
2 Full ROM with gravity removed
1 Muscle flicker
0 No muscle contraction

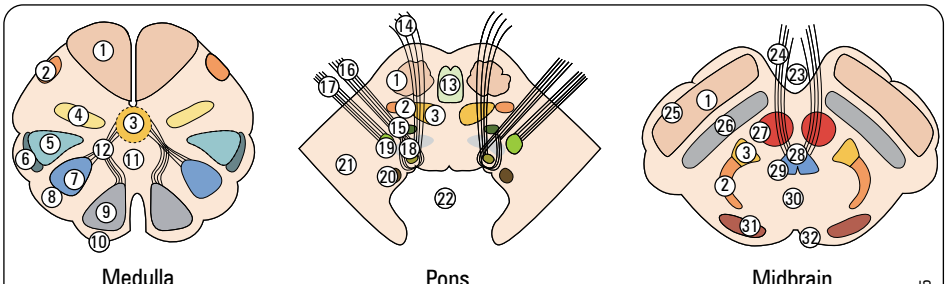
**Deep Tendon Reflexes**

| Root | Muscle Tendon |
|---|---|
| C5/6 | Biceps |
| C6 | Brachioradialis |
| C7 | Triceps |
| C8 | Finger flexors |
| L2/3 | Hip adductors |
| L3/4 | Knee extensors |
| S1/2 | Plantar flexion |

**Deep Tendon Reflex Scoring**
0 Absent
1+ Depressed – elicited with reinforcement only
2+ Normal
3+ Increased
4+ Clonus (≥4 beats)

**Interpreting a Slow or Uncoordinated Rapid Alternating Movement (RAM)**
- Slow RAMs without fatiguing is suggestive of weakness (especially if it is asymmetric)
- Slow RAMs with fatiguing (i.e. decreasing amplitude over time) is suggestive of Parkinsonism
- Uncoordinated RAM is suggestive of cerebellar disorder (i.e. ataxia and irregularly irregular rhythm) or ideomotor apraxia

**Common Cerebellar Findings**
Frontal executive dysfunction/disinhibition, scanning speech, nystagmus, hypermetric saccades, hypotonia, pendular reflexes, intention tremor, ataxic finger-nose/heel-shin/tandem, wide based stance and gait, positive rebound
Midline cerebellar diseases: truncal ataxia
Lateral cerebellar hemisphere diseases: limb ataxia



**Romberg Test**
Stable with eyes open and closed = normal
Stable with eyes open, falls with eyes closed = positive Romberg, suggesting loss of joint position sense

# Coordination Exam and Gait

- coordination exam
  - finger-to-nose, heel-to-shin, knee taps, rapid alternating movements
- stance and gait
  - Romberg test
  - pull test or push and release test for postural instability
  - gait: antalgic, hemiplegic, ataxic, apraxic, Parkinsonian gait, steppage gait, broad-based
  - tandem gait (heel-to-toe test)

See Functional Neuroanatomy software

# Lumbar Puncture

### Indications
- diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
- therapeutic: to administer anesthesia, chemotherapy, contrast media
  - to decrease ICP (pseudotumour cerebri, NPH)

### Contraindications
- mass lesion causing increased ICP, could lead to cerebral herniation; CT first if suspect mass lesion
- infection over LP site/suspected epidural abscess
- low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
- uncooperative patient
- acute confirmed/suspected spinal trauma or congenital spinal abnormalities

The needle for a LP is inserted into one of L3-4, L4-5, or L5-S1 interspaces

### Complications
- tonsillar herniation (rare)
- SDH (rare)
- transient 6th nerve palsy (rare)
- post-LP headache (5-40%): worse when upright, better supine; generally onset within 24 h
  - prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
  - symptomatic treatment: caffeine and sodium benzoate injection
  - corrective treatment: blood patch (autologous)
- spinal epidural hematoma
- infection

Do not delay antibiotics while waiting for a LP if infection is suspected

### LP Tubes
- **tube #1:** cell count and differential: RBCs, WBCs, and differential
  - xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF, diagnostic of SAH)
- **tube #2:** chemistry: glucose (compare to serum glucose) and protein
- **tube #3:** microbiology: Gram stain and C&S
  - specific tests depending on clinical situation/suspicion
    - viral: PCR for herpes simplex virus (HSV) and other viruses
    - bacterial: polysaccharide antigens of *H. influenzae, N. meningitidis, S. pneumoniae*
    - fungal: cryptococcal antigen, culture
    - TB: acid-fast stain, TB culture, TB PCR
- **tube #4:** cytology: for evidence of malignant cells, if clinical suspicion is low for neoplasm, consider sending tube #4 for cell count

RBCs in tube #1>>#5 → traumatic tap
RBCs in tube #1=#5 → SAH

**Table 5. Lumbar Puncture Interpretation (Normal vs. Various Infectious Causes)**

| Condition | Colour | Protein | Glucose | White Blood Cells |
|---|---|---|---|---|
| **NORMAL** | Clear | <0.45 g/L | 60% of serum glucose or >3.0 mmol/L | 0-5 x $10^6$/L |
| **Viral Infection** | Clear or opalescent | Normal or slightly increased<0.45-1 g/L | Normal | <1000 x $10^6$/L Lymphocytes mostly, some PMNs |
| **Bacterial Infection** | Opalescent yellow, may clot | >1 g/L | Decreased (<25% serum glucose or <2.0 mmol/L) | >1000 x $10^6$/L PMNs |
| **Granulomatous Infection (tuberculosis, fungal)** | Clear or opalescent | Increased but usually <5 g/L | Decreased (usually <2.0-4.0 mmol/L) | <1000 x $10^6$/L Lymphocytes |

# Approach to Common Presentations

## Weakness

### Approach
- **mode of onset:** abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrine, neoplastic)
- **course:** worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
- **pattern:** objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- **associated symptoms:** sensory, cortical, autonomic, spinal (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- **history:** family history, developmental history, medications, risk factors, recent/preceding exposures
- **investigations for LMN:** NCS/EMG
- **investigations for UMN:** imaging (brain and/or spinal cord)

### Differential Diagnosis

- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  - generalized
    - myopathy (proximal > distal weakness)
      - endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
      - rheumatologic: polymyositis, vasculitis
      - infectious: HIV, influenza
      - other: collagen vascular disorders, steroids, statins, alcohol, electrolyte disorders
    - NMJ (MG, botulism, LEMS, organophosphate poisoning)
    - cachexia
  - localized
    - UMN (vasculitis, abscess, brain tumour, vitamin B12 deficiency, MS, stroke)
    - radicular pain (i.e. nerve root)
    - anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic)
    - peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
- no objective muscle weakness
  - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  - depression, deconditioning

## Numbness/Altered Sensation

### Approach

- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, reduction/absence of feeling
- determine distribution of sensory loss:
  - nerve root vs. peripheral nerve
  - symmetric stocking-glove pattern (indicative of distal symmetric polyneuropathy)
  - dissociated sensory loss: dorsal column (fine touch, proprioception, vibration) vs. spinothalamic tract (pain and temperature)
- investigations: NCS, blood glucose, vitamin B12 levels, imaging based on associated findings

### Differential Diagnosis

- cerebral: stroke, demyelination, tumour
  - symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumour
  - symptoms: diplopia, vertigo, dysarthria, dysphagia, crossed sensory and/or motor findings
- spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B12 deficiency, disc lesion
  - symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
- neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B12 deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

## Gait Disturbance

### Approach

**1. Characterization of the gait disturbance**
- posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, difficulty turning, tremor, elaborate/inconsistent movements, standing from sitting

**2. Identification of accompanying neurologic signs**
- full neurological exam required (diagnosis often can be made by physical exam alone)

**3. Identify red flags**
- sudden onset, cerebellar ataxia, paresis (hemi-, para- or quadri-), bowel/bladder incontinence

**4. Workup**
- based on etiology – requires blood work, neuroimaging, and urgent neurologist referral

**Central Motor Systems**

**3 components to the control of gait:**
- Pyramidal: main outflow from cortex to spinal cord
- Extrapyramidal: basal ganglia inhibits excess movements
- Cerebellum: affects coordination of gait

**Table 6. Types of Gait Disturbance**

| Location | Description | Disorder |
|---|---|---|
| **Visual Loss** | Broad based gait with tentative steps | Cataract surgery without lens replacement |
| **Proprioceptive Loss** | Sensory ataxia: wide-based with high stepping posture and positive Romberg | Demyelinating neuropathies, paraneoplastic syndrome, tabes dorsalis, MS, compressive myelopathy, B12 deficiency |
| **Peripheral Vestibular Lesion**<br>1. Acute<br>2. Bilateral | 1. Vestibular ataxia<br>2. Disequilibrium | 1. Tumour, trauma, infectious, Ménière's disease<br>2. Ototoxic drugs |
| **Peripheral Nerve Disorder**<br>1. Foot drop<br>2. Lumbosacral radiculopathy | Steppage gait | Acquired/hereditary peripheral neuropathy, compressive peroneal neuropathy, L4-5 radiculopathy |
| **Myopathies** | Waddling gait: broad based, short stepped gait with pronounced lumbar lordosis, rotation of pelvis | Progressive muscular dystrophy |
| **Pyramidal/Corticospinal Tract Lesion**<br>1. Unilateral<br>2. Bilateral | Spastic gait: spastic foot drop, circumduction, scissoring of legs or toe walking with bilateral circumduction | Unilateral: stroke (ischemic/hemorrhagic)<br>Bilateral: cervical spondylosis, cerebral palsy, spinal cord tumour, combined spinal cord degeneration, MS, motor neuron disease |
| **Basal Ganglia** | 1. Parkinsonian gait: small paces, stooped posture, reduced armswing<br>2. Choreic/hemiballistic/dystonic gait | Infarct, Huntington's, Sydenham's chorea, Wilson's disease, SLE, neuroleptic medications, polycythemia vera, genetic dystonia |
| **Cerebellar Disorder** | Cerebellar ataxic gait: wide-based without high stepping; veers to side of lesion<br>Alcoholic gait | Primary and secondary neoplasm, toxins (alcohol), vitamin E deficiency, hypothyroid, hypoxia, hypoglycemia, paraneoplastic syndrome |

# Cranial Nerve Deficits

## CN I: Olfactory Nerve

### Clinical Features
- anosmia associated with a loss of taste

### Differential Diagnosis
- nasal: physical obstruction
  - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- olfactory neuroepithelial: destruction of receptors or their axon filaments
  - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
- central: lesion of olfactory pathway
  - Kallmann syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningioma, aneurysm, PD, MS

If anosmia is not associated with loss of taste, consider malingering

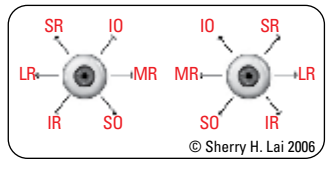

**Figure 10. Diagnostic positions of gaze to isolate the primary action of each muscle**

Kallmann syndrome is a congenital disorder of anosmia and hypogonadotropic hypogonadism

## CN II: Optic Nerve

- see *Neuro-Ophthalmology*, N14

## CN III: Oculomotor Nerve

### Clinical Features
- ptosis, resting eye position is "down and out" (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

### Differential Diagnosis
- **PComm aneurysm:** early mydriasis, then CN III palsy
- **cavernous sinus** (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus
- **midbrain lesion:** complete unilateral CN III palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs ± mydriasis
- **orbital lesion:** associated with optic neuropathy, chemosis, proptosis
- **other:** inflammatory, infection, neoplasia, uncal herniation, trauma

Pupillary constrictor fibres run along outside of nerve, whereas vasculature is contained within nerve
For CN III palsy with a reactive pupil, always think ischemic cause ("pupil sparing")
For CN III palsy with mydriasis, think compressive lesion

Lesions involving the cavernous sinus can lead to cranial nerve palsies of III, IV, VI, V1, and V2 as well as orbital pain and proptosis

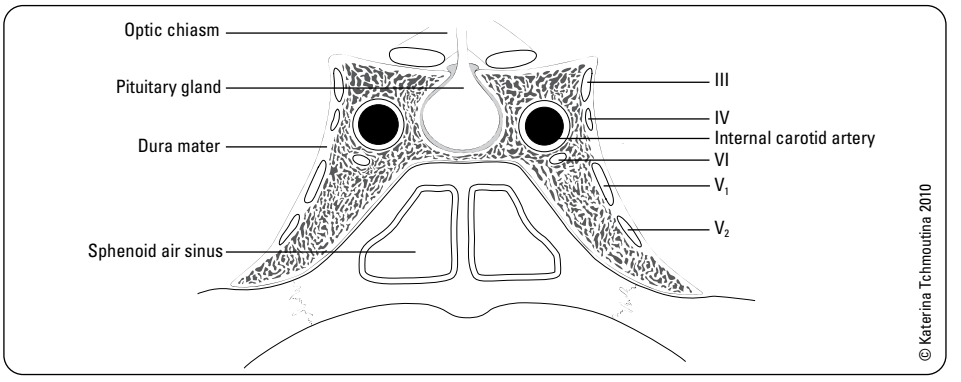

**Figure 11. Cavernous sinus (coronal view)**

**DDx of CN III Palsy**

**iCAM**
**i**schemic
**C**avernous sinus
**A**neurysm (PComm, internal carotid)
**M**idbrain lesion

# CN IV: Trochlear Nerve

### Clinical Features
- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

### Differential Diagnosis
- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

CN IV is the only cranial nerve that decussates at midline and exits posteriorly
A CN IV lesion may cause a contralateral deficit if lesion affects the nucleus

CN IV is at risk of trauma during neurosurgical procedures involving the midbrain because of its long intracranial course

# CN V: Trigeminal Nerve

### Clinical Features
- ipsilateral loss of facial sensation and corneal reflex, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

### Differential Diagnosis
- brainstem: ischemia, tumour, syringobulbia, demyelination
- peripheral: tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve
- trigeminal ganglion: acoustic neuroma, meningioma, fracture of middle fossa
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

**Distinguishing CN III, IV, and VI Lesions**

| | III | IV | VI |
|---|---|---|---|
| **Diplopia** | Oblique | Vertical | Horizontal |
| **Exacerbating** | Near target | Looking down | Far target |
| **Head Tilt** | Up and rotated away | Down and flexed away | Rotated towards |

Jaw deviation is towards the side of a LMN CN V lesion

# CN VI: Abducens Nerve

### Clinical Features
- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

### Differential Diagnosis
- pons (infarction, hemorrhage, demyelination, tumour): facial weakness and contralateral pyramidal signs
- tentorial orifice (compression, meningioma, trauma): false localizing sign of increased ICP
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- ischemia of CN VI: DM, temporal arteritis, HTN, atherosclerosis
- congenital: Duane's syndrome

CN VI has the longest intracranial course and is vulnerable to increased ICP, creating a false localizing sign

# CN VII: Facial Nerve

### Clinical Features
- LMN lesion: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- UMN lesion: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

### Differential Diagnosis
- idiopathic = Bell's palsy, 80-90% of cases (see Otolaryngology, OT22)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay Hunt (VZV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

Forehead is spared in a UMN CN VII lesion due to bilateral innervation of CN VII nuclei from cerebral hemispheres for the frontalis

When screening for dysphagia and assessing aspiration risk, the presence of a gag reflex is insufficient; the correct screening test is to observe the patient drinking water from a cup while observing for any coughing, choking, or "wetness" of voice

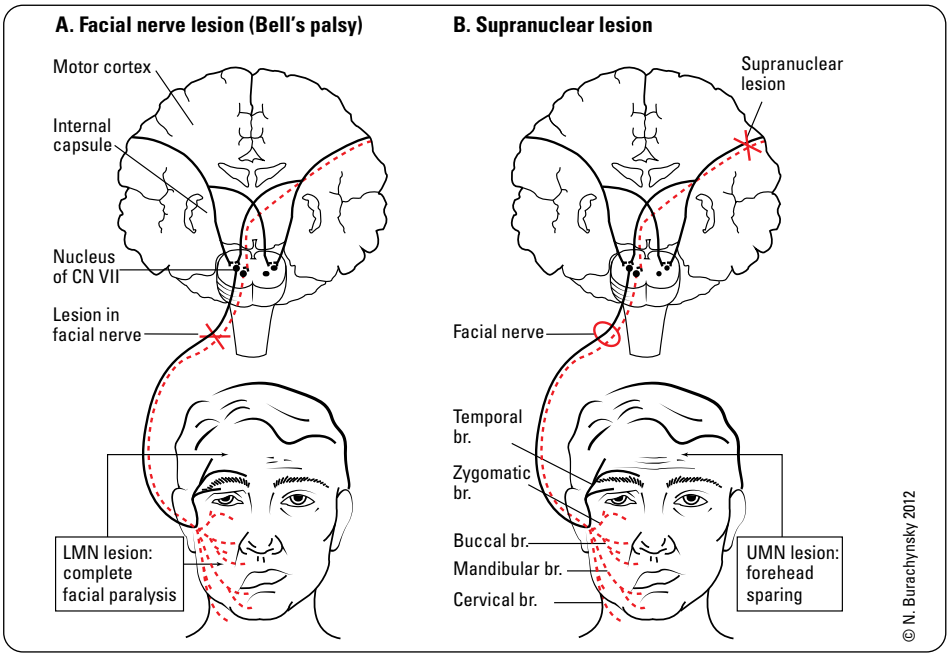

**Figure 12. UMN vs. LMN facial nerve palsy**

**Facial Nerve Branch Memory Aid**
**To Zanzibar By Motor Car**
**T**emporal
**Z**ygomatic
**B**uccal
**M**andibular
**C**ervical

**Differential Diagnosis of Lower Cranial Nerve Deficits (CN IX, X, XI, XII)**
**Intracranial/Skull Base**: meningioma, neurofibroma, metastases, osteomyelitis, meningitis
**Brainstem**: stroke, demyelination, syringobulbia, poliomyelitis, astrocytoma
**Neck**: trauma, surgery, tumours

Normal swallowing is initiated when the tongue moves a bolus back into the palatal archway. Tongue movements are innervated exclusively by CN XII. The bolus stimulates the soft palate to elevate and the bolus is deflected into the oropharynx. Next the pharyngeal constrictors contract, the larynx elevates, and the vocal cords close. Swallowing depends on afferent information via CN V, IX, and X and motor action via CN V, VII, IX, X, and XII. Connections in the nucleus of the tractus solitarius in the medulla (in proximity to the respiratory centre) act as the swallowing centre. Swallowing and breathing are coordinated to prevent aspiration

# CN VIII: Vestibulocochlear Nerve

- see Otolaryngology, OT14

# CN IX: Glossopharyngeal Nerve

### Clinical Features
- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue, absent gag reflex, and dysphagia

### Disorders
- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

# CN X: Vagus Nerve

### Clinical Features
- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
- bulbar dysphagia (brainstem)
  - other causes of dysphagia: see Gastroenterology, G8
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

Uvula deviation is away from the side of a LMN CN X lesion due to impaired ipsilateral palatal elevation

# CN XI: Accessory Nerve

### Clinical Features
- LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
- UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

CN XI is vulnerable to damage during neck surgery

# CN XII: Hypoglossal Nerve

### Clinical Features
- LMN lesion: tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
- UMN lesion: tongue deviation away from lesion; absence of atrophy and fasciculations

# Neuro-Ophthalmology

## Optic Neuritis

- see *Optic Disc Edema*, *Multiple Sclerosis*, N52

## Anterior Ischemic Optic Neuropathy (AION)

- see *Optic Disc Edema*
- non-arteritic (NAION): due to atherosclerosis
- arteritic (AAION): due to giant cell arteritis (see Rheumatology, RH21)

NAION can be caused by use of sildenafil (Viagra®) in rare cases

## Amaurosis Fugax

- see *Ophthalmology*, OP35 and *Stroke*, N48

## Optic Disc Edema

If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results, begin treatment immediately

**Table 7. Common Causes of Optic Disc Edema**

| | Optic Neuritis | Papilledema | AION | CRVO |
|---|---|---|---|---|
| **Age** | <50 yr | Any | >50 yr but usually >70 yr | >50 yr |
| **Vision** | Rapidly progressive monocular central vision loss (↓ acuity and colour vision) with recovery | Late visual loss | Painless unilateral acute field defect over hours to days with ↓ colour vision | Painless unilateral variable vision loss |
| **Symptoms** | Pain (especially with eye movement) | H/A, N/V, local neurological deficits | If GCA: H/A, scalp tenderness, jaw claudication, weight loss, fatigue | Cardiovascular risk factors |
| **Pupil** | RAPD | No RAPD | RAPD | ± RAPD |
| **Fundus** | Disc swelling if anterior Normal disc if retrobulbar | Bilateral disc swelling, retinal hemorrhage, no venous pulsations | Pale segmental disc edema, retinal dot, flame hemorrhages | Swollen disc, venous engorgement, retinal hemorrhage |
| **Etiologies** | MS, viral | Increased ICP | Arteritic: giant cell arteritis Non-arteritic: atherosclerosis | Associated with vasculopathy, thrombus |
| **Investigations** | MRI with gadolinium | Emergent CT; LP if CT is normal to measure opening pressure | CBC, ESR, CRP, temporal artery biopsy | Fluorescein angiogram and coherence tomography |
| **Treatment** | IV methylprednisolone | Treat cause | Consider ASA if non-arteritic; steroids if arteritic | Optimize risk factors, reduce IOP, ± laser, ± VEGF inhibitors |

## Optic Disc Atrophy

- **etiologies:** glaucoma, AION, compressive tumour, optic neuritis, Leber's hereditary optic neuropathy, congenital
- **presentation:** disc pallor, low visual acuity, peripheral vision defect, decreased colour vision
- **treatment:** none (irreversible), aim to prevent

# Abnormalities of Visual Field

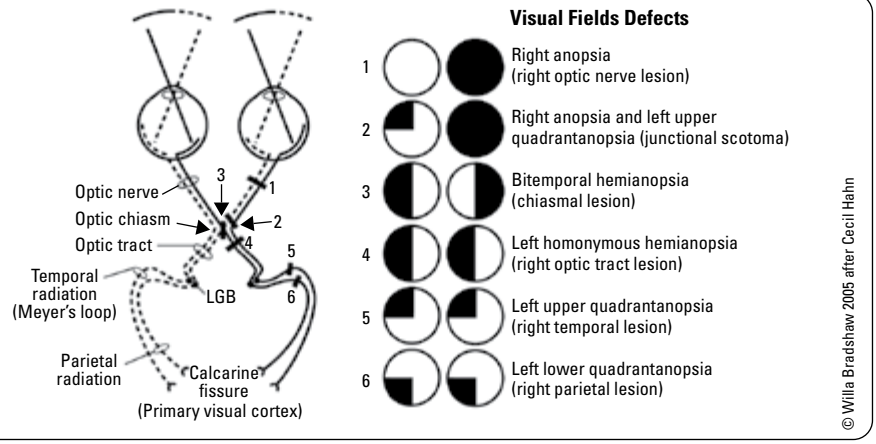

**Figure 13. Characteristic visual field defects with lesions along the visual pathway**

**Bitemporal Hemianopsia DDx by Age**
- Children: craniopharyngioma
- Middle aged (20s to 50s): pituitary mass
- Elderly (>60 yr): meningioma

In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions; macular sparing may occur with occipital lesions

A lesion in a cerebral hemisphere causes eyes to "look away" from the hemiplegia, and to look towards the lesion
A lesion in the brainstem causes the eyes to "look toward" the side of the hemiplegia, and to look away from the lesion

Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)

# Abnormalities of Eye Movements

## Disorders of Gaze

### Pathophysiology
- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

### Clinical Features
- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can be overcome with doll's eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
  - cannot be overcome with doll's eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

### Etiology
- common: infarcts (frontal or brainstem), MS, tumours

## Internuclear Ophthalmoplegia

### Pathophysiology
- results from a lesion in the MLF which disrupts coordination between the CN VI nucleus in the pons and the contralateral CN III nucleus in the midbrain → disrupts conjugate horizontal gaze

### Clinical Features
- horizontal diplopia on lateral gaze, oscillopsia (objects in visual field appear to oscillate)
- gaze away from the side of the lesion: ipsilateral adduction defect and horizontal nystagmus in the contralateral, abducted eye
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

### Etiology
- common: MS, brainstem infarct

### Investigations
- MRI

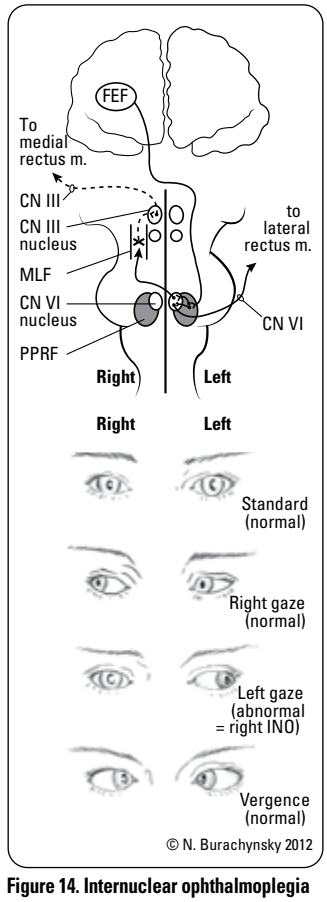

**Figure 14. Internuclear ophthalmoplegia**

# Diplopia

### Etiology – Monocular
- mostly due to benign optical problems (refractive error, cataract) or functional causes

### Etiology – Binocular (due to ocular misalignment)
- muscle: Graves' ophthalmopathy, EOM restriction/entrapment
- neuromuscular junction: MG (see *Myasthenia Gravis*, N38)
- cranial nerve palsy (see *Cranial Nerve Deficits*, N11)
- INO (see *Internuclear Ophthalmoplegia*, N15)
- other
  - orbital trauma (orbital floor fracture), tumour, infection, inflammation
  - Miller-Fisher variant of GBS
  - Wernicke's encephalopathy
  - leptomeningeal disease

### Approach to Diplopia
- monocular (diplopia when one eye open) vs. binocular (diplopia when both eyes open)
- horizontal vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

### Workup
- may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
- indications for neuroimaging
  - bilateral or multiple nerve involvement
  - severe sudden onset headache (rule out aneurysm)

Diplopia worse at the end of the day suggests myasthenia gravis (e.g. fatigable)

If diplopia is only on extremes of gaze, cover each eye in isolation during extremes of gaze
The covered eye that makes the lateral image disappear is the pathological one

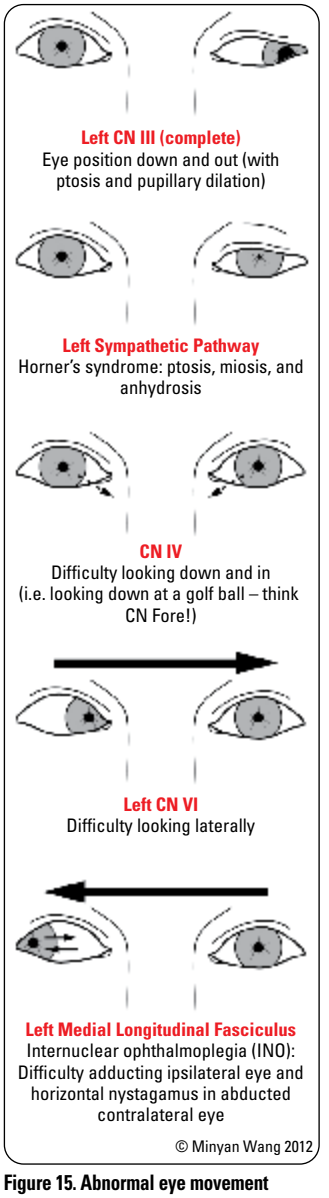

**Figure 15. Abnormal eye movement**

# Nystagmus

- rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- direction of nystagmus is labelled by the rapid component of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

**Table 8. Nystagmus Features**

| | Peripheral (Vestibular) | Central (Brainstem) |
|---|---|---|
| **Direction** | Unidirectional, fast phase away from the lesion | May be bilateral/unidirectional |
| **Nystagmus** | Usually horizontal ± rotatory | Usually vertical |
| **Gaze Fixation** | Relieves nystagmus | Does not relieve nystagmus |
| **Vertigo** | Severe | Mild |
| **Auditory Symptoms** | Common | Extremely rare |
| **Other Neurological Signs** | Absent | Often present |
| **DDx** | Benign paroxysmal positional vertigo, vestibular neuritis, Ménière's disease, toxicity, trauma, Ramsay Hunt syndrome | MS, vascular (brainstem/cerebellar), neoplastic/paraneoplastic |

# Abnormalities of Pupils

- see Ophthalmology, OP28

# Nutritional Deficiencies and Toxic Injuries

- sufficient nutritional intake is required for optimal nervous system functioning; deficiencies in the following key nutrients, among others, may impair central and peripheral nervous system function (potential neurological symptoms are provided)

**Table 9. Nutritional Deficiency Features and Management**

| Vitamin Deficiency | Neurological Clinical Manifestation | Investigation | Treatment* |
|---|---|---|---|
| **Vitamin B12** | Paresthesias and sensory ataxia are the most common initial symptoms<br>Myelopathy (Subacute Combined Degeneration), peripheral neuropathy<br>Neuropsychiatric: memory impairment, change in personality, delirium, and psychosis<br>Optic neuropathy | Serum cobalamin<br>Serum methylmalonic acid<br>Serum homocysteine | IM Vitamin B12 1000 µg for 5 d, then 1/mo or PO B12 1000 µg/d |
| **Folate** | Myelopathy, peripheral neuropathy<br>May be clinically indistinguishable from Vitamin B12 deficiency | Serum folate<br>Homocysteine | PO folate 1 mg tid initially; 1 mg daily thereafter |
| **Copper** | Myelopathy, pyramidal signs (e.g. brisk muscle stretch reflexes at the knees and extensor plantar responses)<br>Severe sensory loss | Serum copper and ceruloplasmin; urinary copper | Discontinue zinc; PO copper 8 mg/d for 1 wk; 6 mg/d for 1 wk; 4 mg/d for 1 wk; 2 mg/d thereafter |
| **Vitamin E** | Ophthalmoplegia, retinopathy, spinocerebellar syndrome with peripheral neuropathy (with signs of cerebellar ataxia) | Serum vitamin E; ratio serum vitamin E to sum of cholesterol and triglycerides | Vitamin E 2200 mg/kg/d PO or IM |
| **Thiamine** | Three manifestations include: beriberi (dry and wet), infantile beriberi, Wernicke-Korsakoff syndrome<br>Alcoholism is a cause of reduced thiamine intake and deficiency | Clinical diagnosis; brain MRI | Thiamine 100 mg IV followed by 50-100 mg IV or IM until nutritional status stable |
| **Pyridoxine (Vitamin B6)** | Painful sensorimotor peripheral neuropathy | Serum pyridoxal phosphate | Pyridoxine 50-100 mg daily |
| **Niacin (Vitamin B3)** | Pellagra: Encephalopathy, dementia, coma, and peripheral neuropathy | Urinary excretion niacin metabolites | Nicotinic acid 25-50 mg daily PO or IM. When supplementing, be aware of "niacin flush" in some patients |

*IM = intramuscular; IV = intravenous; PO = by mouth (orally)

- also consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below

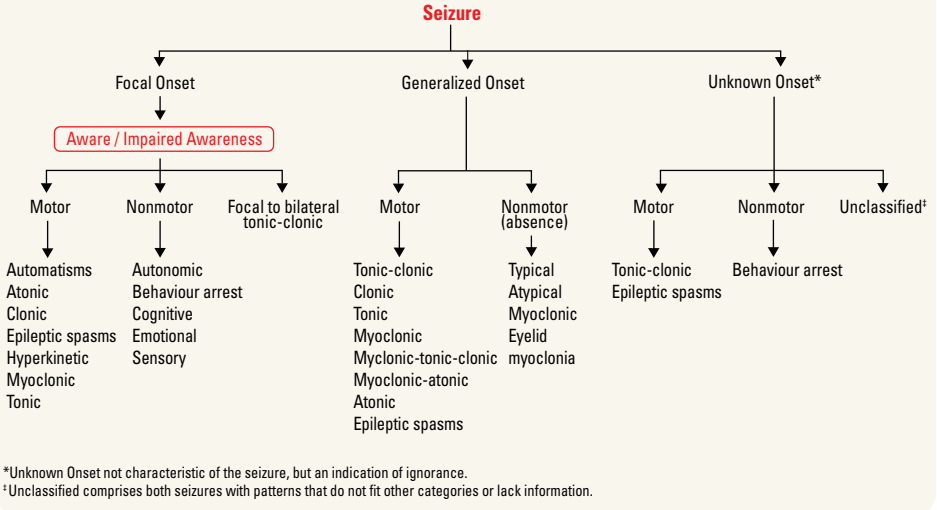
**Table 10. Selected Occupational Neurotoxic Syndromes**

| Toxin | Associated Occupations | Characteristic Neurological Findings |
|---|---|---|
| **Organic Solvents** | Printer, spray painters, industrial cleaners, paint or glue manufacturers, graphic industry, electronic industry, plastic industry | Nausea, H/A, concentration difficulty<br>Long-term exposure may lead to "chronic solvent-induced encephalopathy", characterized by mild-to-severe cognitive impairment |
| **Pesticides** (e.g. insecticides, fungicides, rodenticides, fumigants, herbicides) | Agricultural work, pesticide manufacturing and formulating employees, highway and railway workers, green house, forestry and nursery workers | Parkinson's disease risk increased by ~70% following pesticide exposure |
| **Heavy Metals** (e.g. lead, mercury, manganese, aluminum, arsenic) | Battery and metal production (e.g. solder, pipes), chemical and electronic application industries, steel manufacturing, welders, alloy workers, transportation, packaging, construction | **Lead:** delayed/reversed development, permanent learning disabilities, peripheral neuropathy, seizures, coma, death from encephalopathy (rare)<br>**Mercury:** psychiatric disturbances, ataxia, visual loss, hearing loss, tiredness, memory disturbances<br>**Manganese:** psychiatric symptoms, hallucinations ("manganese madness"), extrapyramidal features, dystonia, parkinsonism (manganism)<br>**Aluminum:** implicated in Alzheimer's pathogenesis<br>**Arsenic:** sleeplessness/sleepiness, irritability, H/A, spasms in muscle extremities and muscle fatigue |
| **Gases** (e.g. carbon dioxide, nitrous oxide, formaldehyde) | Anesthesia, disinfection, manufacture of illuminating gas and water-gas | Cognitive/behavioural and emotional symptoms, parkinsonian syndromes |

## Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications and neurological manifestations

# Seizure Disorders and Epilepsy



## Seizure

### Definitions

- seizure: transient occurrence of signs and/or symptoms due to abnormal hyper-synchronization of neurons
  - can be a symptom of acute insult to the brain such as: alcohol and illicit drug use/withdrawal, brain injury/abnormality (tumour, trauma, vascular), CNS infection, fever (children), metabolic (hypoglycemia, electrolyte abnormalities, liver/renal failure), medications, or be a genetic or inherited cause
- epilepsy: disorder of the brain characterized by an enduring predisposition to generate epileptic seizures, and by the neurobiologic, cognitive, psychological, and social consequences of this condition.
  - diagnosis of an epilepsy syndrome requires:
    1) at least two unprovoked seizures occurring more than 24 hours apart
    2) one unprovoked seizure and a probability of further seizures similar to the general recurrence risk (at least 60%) of two unprovoked seizures, occurring over the next 10 years
  - etiologies: genetic, structural (e.g. prior stroke, tumour, meningo/encephalitis, perinatal insult, vascular malformation, malformation of cortical development, neurodegenerative), or unknown

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

### Classification

*Unknown Onset not characteristic of the seizure, but an indication of ignorance.
‡Unclassified comprises both seizures with patterns that do not fit other categories or lack information.

**Figure 16. Classification of seizures**

**Seizures and Dementia**
Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

### Clinical Features

- **focal (partial) seizures**
  - focal can secondarily generalize, or remain focal
  - focal without impaired awareness (i.e. "simple partial seizures") → focal with impaired awareness (aka "complex partial seizures") → secondarily generalized seizures
  - **focal with intact awareness (simple partial)**
    - motor: dystonic posturing, clonic movements, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste, or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
  - **focal with impaired awareness (complex partial)**
    - patient may appear to be awake but with impairment of awareness
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysmnesic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness
- **generalized seizures**
  - **absence (petit mal):** usually seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - **clonic:** whole body repetitive rhythmic jerking movements
  - **tonic:** whole body muscle rigidity in flexion or extension
  - **tonic-clonic (grand mal)**
    - may have prodrome of unease or irritability hours to days before
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence

**Temporal lobe epilepsy** is suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations
**Frontoparietal cortex seizures** are suggested by contralateral focal sensory or motor phenomena

**Antiepileptic Drug Monotherapy for Epilepsy: A Network Meta-analysis of Individual Participant Data**
Cochrane DB Syst Rev 2017;CD011412
Carbamazepine and lamotrigine are suitable first-line treatments for partial onset seizures with levetiracetam as a suitable alternative. Evidence supports sodium valproate as first-line treatment for generalized tonic-clonic seizures with lamotrigine and levetiracetam as suitable alternatives.

  - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours; may have focal paralysis (Todd's paralysis)
- **myoclonic:** sporadic contractions localized to muscle groups of one or more extremities
- **atonic:** loss of muscle tone leading to drop attack

**Table 11. Classic Factors Differentiating Seizure, Syncope and Pseudoseizure**

| Characteristic | Seizure | Syncope | Pseudoseizure* (Psychogenic non-epileptic seizure) |
|---|---|---|---|
| **Timing** | Day or night (especially from sleep) | Day | Day; other people present |
| **Onset** | Sudden, in any position | Gradual; Upright position (not recumbent) | Provoked by emotional disturbance or suggestion |
| **Early Symptoms or Signs** | Possible specific aura | Lightheadedness, pallor, diaphoresis, tunnel vision | Variable |
| **Duration** | Brief or prolonged | Brief | Often prolonged |
| **Incontinence** | Common | Possible but rare | Rare |
| **Post-Ictal** | Confusion, aphasia, Todd's paresis, fatigue | No | Variable, often none |
| **Motor Activity** | Synchronous, stereotypic, automatisms (common in complex partial), lateral tongue biting, eyes open or eyes rolled back | Occasional brief jerks, can have "convulsive syncope" | Prolonged episodes, opisthotonos, eye closure, irregular extremity movements, shaking head, pelvic thrust, crying, tongue biting at the tip |
| **Injury** | Common | Rare unless from fall | Rare |
| **EEG** | Usually abnormal ± interictal discharges | Normal | Normal |

*Pseudoseizures do not rule out seizures (not uncommon to have both)

**DDx of Convulsions**
Syncope, pseudoseizure, hyperventilation, panic disorder, TIA, hypoglycemia, movement disorder, alcoholic blackouts, migraines (confusional, vertebrobasilar), narcolepsy (cataplexy)

Note that frontal seizures (rare) can look like a pseudoseizure due to odd motor activity that may occur

- alcoholic withdrawal seizures may occur up to 2 d from the last exposure to alcohol (see Emergency Medicine, ER54)

### Investigations
- CBC, electrolytes, fasting blood glucose, $Ca^{2+}$, $Mg^{2+}$, ESR, Cr, liver enzymes, CK, prolactin
- also consider toxicology screen, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
  (Note: Neuroimaging may be normal in up to 90% of cases following the first unprovoked seizure)
- LP (if fever or meningismus)
- EEG (Note: EEG is specific but not sensitive)

By law, the Ministry of Transportation in most provinces must be contacted for all patients who have had a seizure; patients will have their license suspended until seizure free for 6 mo; commercial drivers face a longer wait

EEG findings suggestive of epilepsy: abnormal spikes, polyspike discharges, spike-wave complexes

51% of the EEGs within 24 h of the first seizure are positive in epilepsy. If the first routine EEG is normal, the yield of EEGs falls with each subsequent EEG, and thus a sleep EEG should be considered

### Treatment
- avoid precipitating factors
- indications for antiepileptic drugs (AED): EEG with epileptiform activity, remote symptomatic cause (organic brain disease, prior head injury, or CNS infection), abnormal neurologic examination or findings on neuroimaging, nocturnal seizure, recurrent unprovoked seizure
- psychosocial issues: stigma of seizures, education of patient and family, status of driver's license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- refer for evaluation for possible surgical treatment if focal and refractory

**Medical Emergency**: Status epilepticus can cause irreversible brain damage without treatment

## Status Epilepticus

- **definition:** medical emergency involving unremitting seizure or successive seizures without return to baseline state of >5 min
- **complications:** anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- **initial measures:** ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal $O_2$, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
- **blood work:** electrolytes, $Ca^{2+}$, $Mg^{2+}$, $PO_4^{3-}$, glucose, CBC, toxicology screen, EtOH level, AED levels
- **focused history:** onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
- **physical exam** (once seizures controlled): LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
- **post-treatment stabilization:** CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

The most common causes of status epilepticus are failure to take AEDs and first presentation of epilepsy
Despite being a common cause of seizures, EtOH withdrawal is a rare cause of status epilepticus

Rule out non-convulsive status epilepticus in any patient who is still unconscious >20 min post-ictal; order a stat EEG if unsure

Complex partial status epilepticus can resemble schizophrenia or psychotic depression

### Antiepileptic Drugs

- focal and most generalized seizures
  - valproate (Depakene®), lamotrigine (Lamictal®), levetiracetam (Keppra®), topiramate (Topamax®), phenobarbital (Phenobarb®), primidone, zonisamide, rufinamide (Banzel®), felbamate, benzodiazepines
- primarily focal seizures (± 2° generalization)
  - carbamazepine (Tegretol®), phenytoin (Dilantin®), gabapentin (Neurontin®), lacosamide (Vimpat®), oxcarbazepine (Trileptal®), eslicarbazepine acetate (Aptiom®), pregabalin (Lyrica®), tiagabine (Gabitril®), vigabatrin (Sabril®)
- absence seizure: ethosuximide (Zarontin®)

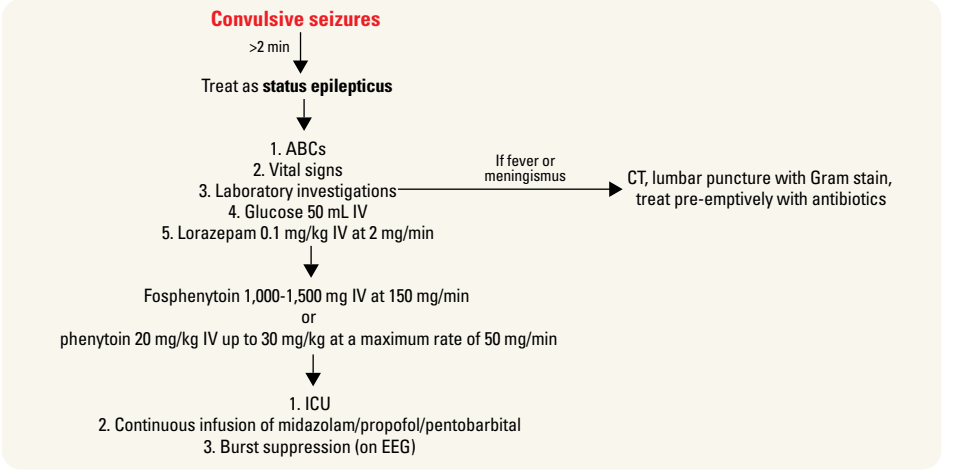


**Figure 17. Status epilepticus treatment algorithm**

Teratogenicity of anticonvulsants includes neural tube defects, cleft palate, urogenital malformations, and heart defects. Advise patient planning pregnancy to take 1-4 mg/d of folic acid. Optimize AEDs with lowest possible dose associated with good seizure control, preferably monotherapy if possible. The risk of fetal malformations with AEDs is 2x the general population; highest risk associated with valproic acid and/or 2+ concurrent AEDs. Consider pre-conception AED levels if patient is well-controlled, monthly serum levels during pregnancy, and titrate AED to maintain pre-conception serum levels. Refer to high risk OB for intrapartum fetal screening

# Behavioural Neurology

- see Psychiatry, PS22

## Acute Confusional State/Delirium

**Table 12. Selected Intracranial Causes of Acute Confusion**

| | Etiology | Key Clinical Features | Investigations |
|---|---|---|---|
| **Vascular** | Subarachnoid hemorrhage | Thunderclap H/A, increased ICP, meningismus, loss of consciousness | CT, LP<br>Angiography if CT and LP negative |
| | Stroke/TIA | Focal neurological signs | CT, MRI |
| **Infectious** | Meningitis | Fever, H/A, nausea, photophobia, meningismus | CT, LP |
| | Encephalitis | Fever, H/A, ± seizure<br>Focal neurological signs | CT, LP<br>MRI |
| | Abscess | Increased ICP<br>Focal neurological signs | CT with contrast (often ring enhancing lesion) |
| **Traumatic** | Diffuse axonal shear, epidural hematoma, SDH | Trauma Hx<br>Increased ICP<br>Focal neurological signs | CT<br>MRI |
| **Autoimmune** | Acute CNS vasculitis | Skin rash, active joints | ANA, ANCA, RF<br>MRI<br>Angiography |
| | Paraneoplastic encephalitis (anti-NMDA-R) | Onset: psychiatric features, memory loss, seizures<br>Delayed: movement disorder, and changes in BP, HR, and temperature | Serum and CSF (test for presence of antibodies), search for primary neoplasm |
| **Neoplastic** | Mass effect/edema, hemorrhage, seizure | Increased ICP<br>Focal neurological signs<br>Papilledema | CT<br>MRI<br>Search for primary neoplasm if metastatic disease |
| **Seizure** | Status epilepticus | See *Seizure Disorders and Epilepsy*, N18 | EEG |
| **Primary Psychiatric** | Psychotic, mood, and anxiety disorder | No organic signs or symptoms | No specific tests |

**Table 12. Selected Intracranial Causes of Acute Confusion** (continued)

| | Etiology | Key Clinical Features | Investigations |
|---|---|---|---|
| **Other** | Drugs (e.g. cocaine) | Chest pain, cough with black sputum, new-onset seizure, HTN, increased ICP, dyspnea | Vital signs<br>Serum chemistry and electrolyte analysis |
| | Medications (with anticholinergic side effects) | Flushing, dry skin and mucous membranes, mydriasis with loss of accommodation | Serum chemistry and electrolyte analysis |
| | Neuroleptic Malignant Syndrome | Antipsychotic medication use<br>Muscle rigidity<br>Hyperthermia<br>Autonomic instability | Serum chemistry and electrolyte analysis |

# Mild Neurocognitive Disorder (Mild Cognitive Impairment)

## Definition
- cognitive changes with measurable deficits in one or more cognitive domain
- preservation of independence or minimal impairment in ADLs and IADLs and not meeting criteria for major NCD
- amnestic (precursor to AD) vs. non-amnestic

## Epidemiology
- mild NCD: 2-10% at age 65 yr and 5-25% by age 85 yr

## Risk Factors
- vascular: hypertension, diabetes mellitus, obesity, cardiac disease, apolipoprotein E epsilon 4 genotype

## Clinical Features
- cognitive impairment with different subtypes
  - single domain vs. multiple domains (e.g. memory, visual spatial function, attention, executive function)
  - amnestic (memory impairment) vs. nonamnestic (memory function preserved)
  - amnestic subtype is the most common and most associated with AD pathology
  - important to ascertain that memory complaints represent change from baseline
- neuropsychiatric symptoms: depression (50%), irritability, anxiety, aggression, and apathy

## Investigations
- establish a baseline for follow-up
- clinical interview with patient and caregivers is the cornerstone of mild NCD evaluation
- neuropsychological testing
  - MMSE (not sensitive to early cognitive change) or MoCA (more sensitive, score <26 is impaired); should not be used in isolation
  - if abnormal, follow-up in one year to monitor cognitive and functional decline
- neuroimaging
  - role uncertain; a non-contrast brain CT is often ordered to evaluate for structural abnormalities (CVD, SDH, NPH, or mass lesion)
- other testing to exclude treatable conditions and underlying psychiatric conditions

## Treatment
- non-pharmacologic management: exercise training for 6 mo is likely to improve cognition; insufficient evidence to support or refute cognitive intervention, it may improve outcome on select cognitive measures
- no evidence for cholinesterase inhibitors, anti-inflammatory agents, vascular risk factor modification

## Prognosis
- development of major NCD for age ≥65 is 14.9% after 2 yr
- relative risk of major NCD is 3.3 after 2-5 yr

# Major Neurocognitive Disorder (formerly Dementia)

- see Psychiatry, PS23

## Definition
- acquired, generalized, and (usually) progressive impairment of cognitive function associated with impairment in ADLs/iADLs (i.e. shopping, food preparation, finances, medication management)
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
  A) concern of the individual or a knowledgeable informant AND
  B) substantial impairment in cognitive performance either documented by standardized neuropsychological testing, or quantified clinical assessment

Delirium is a medical emergency carrying significant risk of morbidity and mortality; it is characterized by acute onset, disorientation, fluctuating level of consciousness, poor attention, and marked psychomotor changes

Visual hallucinations more commonly indicate organic disease

**Prevalence of Depression in Patients with Mild Cognitive Impairment: A Systematic Review and Meta-Analysis**
JAMA Psychiatry 2017;74(1):58-67
**Objectives**: To estimate the prevalence of depression in individuals with mild cognitive impairment.
**Methods**: Review of articles with patients with mild cognitive impairment as a primary study group, reported depression/depressive symptoms using a validated tool, and reported the prevalence of depression in patients with mild cognitive impairment.
**Results**: Pooled prevalence of depression patients with mild cognitive impairment was 32% (95% CI 27-37%). Prevalence in community-based populations (25%, 95% CI 19-30) was significantly lower than clinic-based populations (40%, 95% CI 32-48).
**Conclusions**: Prevalence of depression in patients with mild cognitive impairment is high.

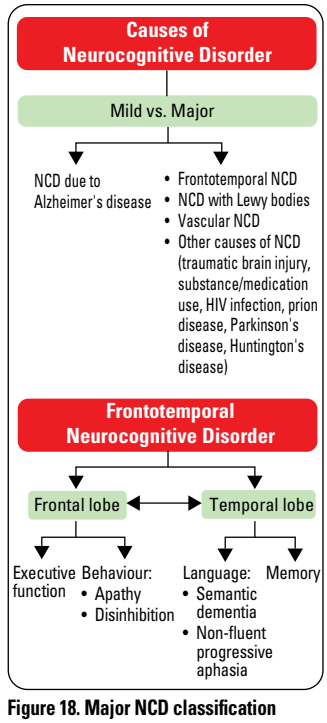

**Figure 18. Major NCD classification**

- see Psychiatry, PS23 for DSM-5 diagnostic criteria
- in comparison, mild NCD does not affect ADLs
  - mild NCD represents an intermediate stage between major NCD and normal aging

## Epidemiology
- major NCD: 1-2% at age 65 yr and reaching as high as 30% by age 85 yr
- major NCD due to Alzheimer's disease is uncommon before age 60 yr
- major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with increasing age

## Etiology
- see Table 13
- reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, normal pressure hydrocephalus (NPH), depression (pseudodementia), intracranial tumour, SDH, hypercalcemia (secondary to elevated PTH)
- must rule out delirium

## History
- "geriatric giants"
  - confusion/incontinence/falls
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects, driving)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
  - polypharmacy and compliance (sedative hypnotics, antipsychotics, antidepressants, anticholinergics)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS, head trauma history
- alcohol, smoking
- collateral history

## Physical Exam
- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings
- general physical exam with focus on CVD, patient-specific risk factors, and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

## Investigations
- rule out reversible causes
  - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
  - electrolytes, LFTs, renal function, lipids, serum calcium
  - CT head, MRI as indicated, SPECT (optional)
  - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver capacity and wellbeing, power of attorney, legal will, advanced medical directives, patient and caregiver safety

**Table 13. Selected Causes of Major NCD (Dementia)**

| Etiology | Key Clinical Features | Investigations |
|---|---|---|
| **PRIMARY DEGENERATIVE** | | |
| Alzheimer's disease | Memory impairment<br>Aphasia, apraxia, agnosia | CT or MRI, SPECT |
| Dementia with Lewy bodies | Visual hallucinations<br>Parkinsonism<br>Fluctuating cognition | CT or MRI, SPECT |
| Frontotemporal dementia (e.g. Pick's disease) | Behavioural presentation: disinhibition, perseveration, decreased social awareness, mental rigidity, memory relatively spared<br>Language presentation: progressive non-fluent aphasia, semantic dementia | CT or MRI, SPECT |
| Huntington's disease | Chorea | Genetic testing |
| **VASCULAR** | | |
| Vascular cognitive impairment (previously Multi-infarct dementia) | Bradyphrenia without features of parkinsonism (slow thinking, slow rate of learning, slow gait)<br>Dysexecutive syndrome<br>May be abrupt onset<br>Stepwise deterioration is classic but progressive deterioration is most common | CT or MRI, SPECT |
| CNS vasculitis | Systemic signs and symptoms of vasculitis | ANA; ANCA; RF<br>CT or MRI<br>Angiography |

**Sensitivity and Specificity**

| Tool | Sensitivity | Specificity |
|---|---|---|
| MMSE | 87% | 82% |
| Clinical Judgment | 85% | 82% |
| DSM IV | 76% | 80% |

**Vitamin $B_{12}$ Deficiency Symptoms**
- Macrocytic anemia, pallor, SOB, fatigue, chest pain, palpitations
- Confusion or change in mental status (if advanced)
- Decreased vibration sense
- Distal numbness and paresthesia
- Weakness with UMN findings
- Diarrhea, anorexia

**Major NCD Considerations for Management**

**ABCDs**
**A**ffective disorders, **A**DLs
**B**ehavioural problems
**C**aretaker, **C**ognitive medications and stimulation
**D**irectives, **D**riving
**S**ensory enhancement (glasses/hearing aids)

**Most Common Causes of Rapidly Progressive Neurodegenerative Dementia (Less than 4 yr Survival): CJD, Frontal Temporal Lobar Dementia, Tauopathies, Diffuse Lewy Body Disease, and AD**
*Arch Neurol* 2009;66:201-207
Head turning sign: when patient is looking at his/her caregiver for answers after being asked a question in clinical interviews
60% sensitivity, 98% specificity for diagnosis of cognitive Impairment

| Early Signs of Major NCD | Normal Aging |
|---|---|
| Forgetting the names of close relations | Forgetting the names of acquaintances |
| Increased frequency of forgetting | Briefly forgetting part of an experience |
| Repeating phrases/ stories in the same conversation | Not putting away things properly |
| Unpredictable mood changes | Mood changes in response to appropriate causes |
| Decreased interest in activities and difficulty making choices | Changes in usual interests |

**Table 13. Selected Causes of Major NCD (Dementia)** (continued)

| Etiology | Key Clinical Features | Investigations |
|---|---|---|
| **INFECTIOUS** | | |
| Chronic meningitis | Fever, H/A, nausea<br>Meningismus<br>Localizing neurological deficits | CT, LP |
| Chronic encephalitis | Fever, headache | CT or MRI |
| Chronic abscess | Increased ICP<br>Localizing neurological deficits | CT with contrast |
| HIV | See Infectious Diseases, ID27 | HIV serology |
| Creutzfeldt-Jakob disease | Rapidly progressive, myoclonus | EEG, CT or MRI, LP |
| Syphilis | Ataxia, myoclonus, tabes dorsalis | LP, CT, or MRI<br>VDRL |
| **TRAUMATIC** | | |
| Diffuse axonal shear, epidural hematoma, subdural hematoma | Trauma Hx<br>Increased ICP, papilledema<br>Localizing neurological signs | CT |
| **RHEUMATOLOGIC** | | |
| SLE | See Rheumatology, RH11 | MRI<br>ANA, anti-dsDNA |
| **NEOPLASTIC** | | |
| Mass effect/edema, hemorrhage, seizure<br>Paraneoplastic encephalitis | Increased ICP<br>Localizing neurological signs<br>Systemic symptoms of cancer | CT with contrast<br>MRI<br>Paraneoplastic antibodies |
| **OTHER** | | |
| Normal pressure hydrocephalus | Gait disturbances<br>Urinary incontinence<br>See Neurosurgery, NS9 | CT or MRI |

**Cholinesterase Inhibitors for Dementia with Lewy Bodies (DLB), Parkinson's Disease Dementia (PDD) and Cognitive Impairment in Parkinson's Disease (CIND-PD)**
Cochrane DB Syst Rev 2012;3:CD006504
**Study**: Meta-analysis of RCTs assessing efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD.
**Results**: The six trials (n=1236) included demonstrated therapeutic benefit of cholinesterase inhibitors for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase inhibitors were associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine but not with donepezil. Fewer deaths occurred in the treatment group (OR 0.28).
**Conclusion**: Current evidence supports use of cholinesterase inhibitors for patients with PDD but its role in DLB and CIND-PD is still unclear.

# Major or Mild NCD due to Alzheimer's Disease

- see Psychiatry, PS24

## Definition

- beyond criterion for NCD, the core features of Alzheimer's disease include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnestic
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate-severe phase: visuoconstructional/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnestic presentation (one of the following):
  1. aphasia: language disturbance
  2. apraxia: impaired ability to carry out motor activities despite intact motor function
  3. agnosia: failure to recognize or identify objects despite intact sensory function

**4 As and one D of AD**
**A**nterograde amnesia
**A**phasia
**A**praxia
**A**gnosia
**D**isturbance in executive function
(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

## Pathophysiology

- genetic factors
  - minority (<1%) of AD cases are familial (autosomal dominant), associated with early onset AD (<65 yr)
  - 3 major genes, responsible for 5-10% of early onset AD cases, for autosomal dominant AD have been identified:
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
    - the E4 polymorphism of apolipoprotein E (APOE) is a susceptibility genotype (E2 is protective)
    - note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (not necessarily specific for AD)
  - gross pathology
    - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)

Down syndrome predisposes to early onset of Alzheimer's (i.e. age of ~40) due to three copies of the amyloid gene (APP)

- microscopic pathology
  - senile amyloid beta plaques (extracellular deposits of amyloid in the grey matter of the brain)
  - loss of synapses
  - neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
  - loss of cholinergic neurons in the nucleus basalis of Meynert that project diffusely throughout the cortex
- biochemical pathology
  - 50-90% reduction in action of choline acetyltransferase

## Epidemiology
- 1/12 of population 65-75 yr of age
- up to 1/3 population >85 yr of age
- very rare <65 yr of age
- accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

## Risk Factors
- age is the greatest risk factor
- genetic susceptibility polymorphism: apolipoprotein E4 increases risk and decreases age of onset
- other factors include: traumatic brain injury, family history, Down syndrome, low education, and vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

## Clinical Features
- cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning, and executive function
- behavioural and psychiatric manifestations (80% of those with major NCD)
  - mild NCD: major depressive disorder and/or apathy
  - major NCD: psychosis, irritability, agitation, combativeness, and wandering
- motor manifestations (late)
  - gait disturbance, dysphagia, incontinence, myoclonus, and seizures

## Investigations
- perform investigations to rule out other potentially reversible causes of dementia
- EEG: usually normal in mild-moderate stages, slow waves in moderate-advanced stages. May observe generalized slowing (nonspecific)
- MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
- SPECT: hypoperfusion in temporal and parietal lobes
- PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of beta-amyloid plaque in neuronal tissue
- LP: amyloid beta protein can be measured in CSF

## Treatment
- acetylcholinesterase inhibitors (donepezil, rivastigmine, galantamine) slow the decline in cognitive function
- do not prolong life expectancy but reduce morbidity
- relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
- galantamine is contraindicated in patients with hepatic/renal impairment
- memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
- behavioural symptom management

1. pharmacologic
   - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
   - trazodone for sleep disturbance
   - antidepressants (SSRIs)
2. non-pharmacologic
   - redirection
   - explore inciting factors for behaviour and modify behaviour of patient or caregiver
   - family support and daycare facilities

## Prognosis
- mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
- death commonly results from aspiration

**Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer's Disease: Outcomes from CATIE-AD**
Am J Psychiatry 2011;168:831-839
**Study**: 421 outpatients with Alzheimer's disease and psychosis or agitated/aggressive behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blinded RCT. MMSE and Alzheimer's Disease Assessment Scale (ADAS) scores were measured at 36 wk.
**Results**: Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (– 0.067/wk vs. -0.007/wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.001/wk).
**Conclusions**: Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.

# Major or Mild NCD with Lewy Bodies (formerly Dementia with Lewy Bodies)

### Definition
- NCD characterized by progressive cognitive impairment (with early changes in complex attention and executive function) and recurrent complex visual hallucinations
- core diagnostic features
  - fluctuating cognition with pronounced variations in attention and alertness
  - recurrent visual hallucinations that are well formed and detailed
  - one or more spontaneous cardinal features of parkinsonism (bradykinesia, rest tremor, or rigidity), with onset subsequent to development of cognitive decline
  - rapid eye movement (REM) sleep behaviour disorder
- suggestive/supportive features
  - severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)
  - repeated falls, syncope, or transient episodes of unexplained loss of consciousness
  - auditory or other nonvisual hallucinations, systematic delusions, and depression

### Etiology and Pathogenesis
- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

### Diagnostically Suggestive Markers
- low striatal dopamine transporter uptake on SPECT or PET
- relative preservation of medial temporal structures on CT/MRI

### Epidemiology
- 0.1-5% of the general elderly population
- Lewy bodies are present in 20-35% of all dementia cases (more common in males)

### Treatment
- acetylcholinesterase inhibitors (e.g. donepezil)

### Prognosis
- average duration of survival 5-7 yr

# Major or Mild Frontotemporal NCD (formerly Frontotemporal Dementia)

### Definition
- group of disorders caused by progressive cell degeneration in the brain's frontal or temporal lobes
  - deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, increased distractibility) with relative sparing of learning, memory, and perceptual-motor function
- "probable" is distinguished from "possible" frontotemporal NCD by:
  - evidence of causative frontotemporal NCD genetic mutation, from either family history or genetic testing
  - evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
  - evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or SPECT

### Behavioural Variant FTD
- most common variant
- insidious onset: must show progressive deterioration of behaviour and/or cognition by observation or history
- typically early symptom presentation (i.e. within the first 3 yr)
- at least 3/5 of the following symptoms must be present and persistent/recurrent:
  - behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
  - apathy or inertia (decreased initiation or continuation of behaviour, requiring cues/prompts, less likely to initiate or sustain conversations)
  - loss of sympathy or empathy (diminished response to others' needs/feelings, social interest)
  - preservative, stereotyped, or compulsive/ritualistic behaviour
  - hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)

### Language Variants (Primary Progressive Aphasia)
- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization ("thing") or supraordinate categories ("animal" for "dog")
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

### FTD Movement Disorders
- corticobasal degeneration (CBD) (see Parkinsonism)
- progressive supranuclear palsy (PSP) (see Parkinsonism)

### Etiology and Pathogenesis
- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (Tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes; cortical thinning; possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

### Epidemiology
- 4th most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals younger than 65 yr

### Prognosis
- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical Alzheimer's disease

## Major or Mild Vascular NCD

### Definition
- diagnosis of major or mild NCD with determination of CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
- neuroimaging evidence of cerebrovascular disease comprises one or more of the following:
  - one or more large vessel infarct or hemorrhage
  - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
  - two or more lacunar infarcts outside the brainstem
  - extensive and confluent white matter lesions
- for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
- for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease and one or more lacunae is generally necessary
- associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

### Etiology and Pathogenesis
- major risk factors are the same as those for CVD (i.e. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

### Epidemiology
- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages ≥80) to 44.6% (ages ≥90)
- higher prevalence in African Americans
- prevalence higher in males than in females

# Creutzfeldt-Jakob Disease

- rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
- investigations: CSF analysis, MRI brain (cortical (i.e. cortical ribbon sign) and/or subcortical (hockey stick sign) FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy
- no treatments currently exist

Prion proteins have a normal form and an infectious form, which results from conversion of the protein from α-helix (normal) to β-pleated sheet (abnormal); these abnormally folded proteins aggregate leading to neuronal loss

# Aphasia

## Definition

- an acquired disturbance of language characterized by errors in language production, writing, comprehension, or reading

## Neuroanatomy of Aphasia

- Broca's area (posterior inferior frontal lobe) is involved in language production (expressive)
- Wernicke's area (posterior superior temporal lobe) is involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke's and Broca's areas

>99% of right-handed people have left hemisphere language representation

70% of left-handed people have left hemisphere language representation, 15% have right hemisphere representation, and 15% have bilateral representation

## Assessment of Language

- assessment of context
  - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  - spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)

**Types of Paraphasias**
Semantic ("chair" for "table")
Phonemic ("clable" for "table")

Aphasia localizes the lesion to the dominant cerebral hemisphere

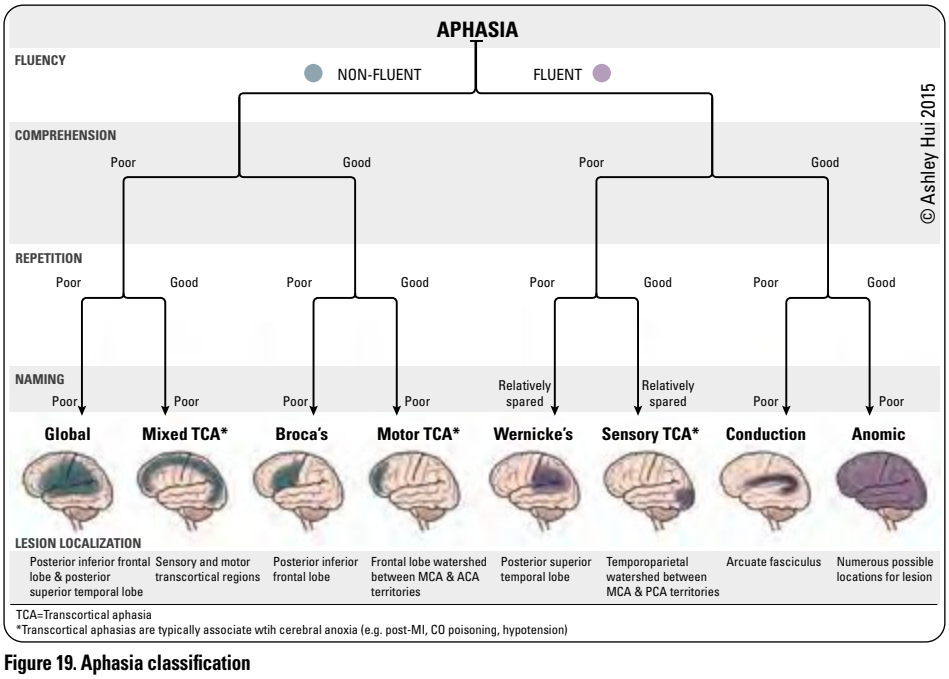

**Figure 19. Aphasia classification**

# Apraxia

## Definition
- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

## Clinicopathological Correlations

**Table 14. Apraxia**

| | Description | Tests | Hemispheres |
|---|---|---|---|
| **Ideomotor** | Inability to perform skilled learned motor sequences | Blowing out a match, combing one's hair | Left |
| **Ideational** | Inability to sequence actions | Preparing and mailing an envelope | Right and left |
| **Constructional*** | Inability to draw or construct | Copying a figure | Right and left |
| **Dressing*** | Inability to dress | Dressing | Right |

*Refers specifically to the inability to carry out the learned movements involved in construction, drawing, or dressing; not merely the inability to construct, draw, or dress. Many skills aside from praxis are needed to carry out these tasks.

# Agnosia

## Definition
- inability to recognize the significance of sensory stimuli in the presence of intact sensation and naming

## Clinicopathological Correlations

**Table 15. Agnosias**

| | Description | Lesion |
|---|---|---|
| **Apperceptive Visual Agnosia** | Inability to name or demonstrate the use of an object presented visually 2° to distorted visual perception<br>Recognition by touch remains intact | Bilateral temporo-occipital cortex |
| **Associative Visual Agnosia** | Inability to name an object presented visually 2° to disconnect between visual cortex and language areas<br>Visual perception is intact as demonstrated by visual matching | Bilateral inferior temporo-occipital junction |
| **Prosopagnosia** | Inability to recognize familiar faces in the presence of intact visual perception and intact auditory recognition | Bilateral temporo-occipital areas or right inferior temporo-occipital region |
| **Colour Agnosia** | Inability to perceive colour | Bilateral inferior temporo-occipital lesions |
| **Impaired Stereognosis** | Inability to identify objects by touch | Anterior parietal lobe in the hemisphere opposite the affected hand |
| **Finger Agnosia** | Inability to recognize, name, and point to individual fingers | Dominant hemisphere parietal-occipital lesions |

**Parietal Lobe Lesions**
- Lesions of the dominant parietal lobe are characterized by Gerstmann's syndrome: acalculia, agraphia, finger agnosia, and left-right disorientation
- Lesions of the non-dominant parietal lobe are characterized by neglect, anosognosia, and asomatognosia
- Cortical sensory loss (graphesthesia, astereognosis, impaired 2 point discrimination, and extinction) can be seen with left or right parietal lesions

# Mild Traumatic Brain Injury

## Definition
- mild TBI = concussion
- trauma-induced transient alteration in mental status that may involve loss of consciousness
- hallmark symptoms: confusion and amnesia, which may occur within minutes
- loss of consciousness (if present) less than 30 min, initial GCS between 13-15, post-traumatic amnesia <24 h

- Extent of retrograde amnesia correlates with severity of injury
- Regained from most distant to recent memories

## Epidemiology
- 75% of TBIs are estimated to be mild; the remainder are moderate or severe (see Neurosurgery, NS32 and Emergency Medicine, ER8)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

## Clinical Features
- impairments following mild TBI
  - somatic: headache, sleep disturbance, nausea, vomiting, and blurred vision
  - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  - emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
- associated conditions: brain contusion, diffuse axonal injury, C-spine injury

### Investigations
- neurological exam to identify focal neurologic deficits
- neurocognitive assessment
  - simple orientation questions are inadequate to detect cognitive changes
  - initial assessment of severity is determined by Glasgow Coma Scale
    - mild: 13-15, moderate: 9-12, severe: 3-8
  - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
  - x-ray skull: not indicated for routine evaluation of mild TBI
  - CT head as indicated by Canadian CT Head Rules
  - MRI not indicated in initial evaluation; consider if continued or worsening symptoms despite normal CT

### Treatment
- observation for first 24 h after mild TBI because of risk of intracranial complications
- emergency department for assessment if any loss of consciousness or persistent symptoms
- hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
- early rehabilitation to maximize outcomes
  - OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
- pharmacological management of headaches, pain, depression
- CBT, relaxation therapy
- follow Return to Play guidelines (www.thinkfirst.ca)

### Prognosis
- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- patients with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequelae include:
  - post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  - post-traumatic headaches: begin within 7 d of injury
  - post-traumatic epilepsy: approximately 2% risk post-mild TBI; prophylactic anticonvulsants are not effective
  - post-traumatic vertigo

# Neuro-Oncology

## Paraneoplastic Syndromes

- see Endocrinology, E51

## Tumours of the Nervous System

- see Neurosurgery, NS11

# Movement Disorders

## Function of the Basal Ganglia

- the cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, where they then activate two pathways: direct and indirect
  - direct: cortex activates the thalamus, allowing movement
  - indirect: inhibits the thalamus and preventing movement

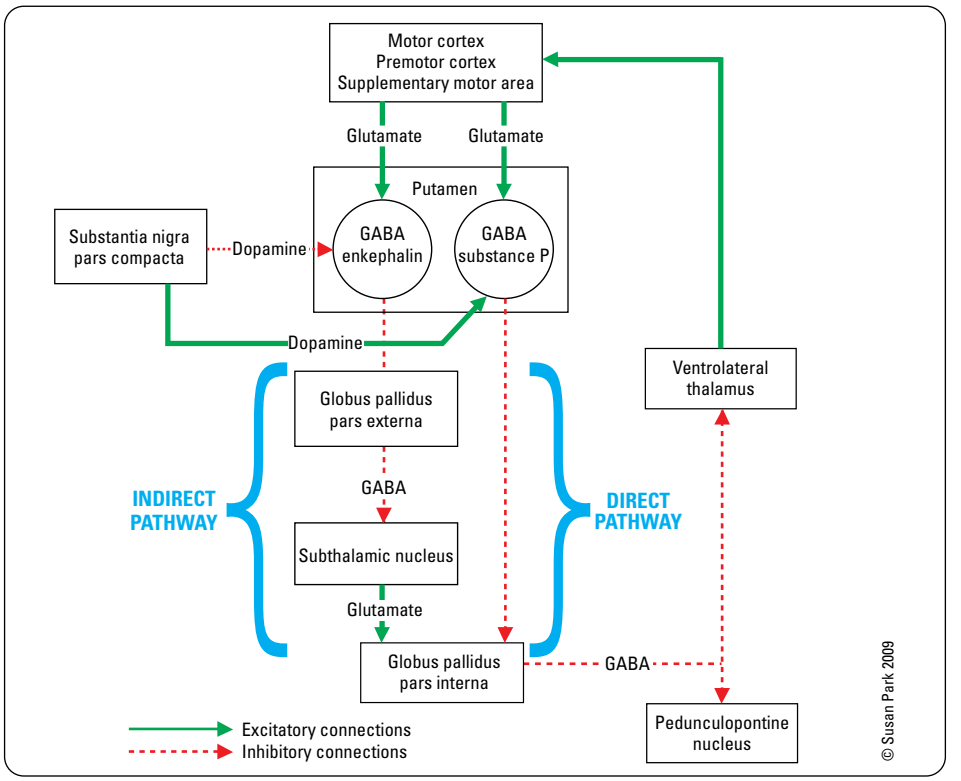

**Figure 20. Neural connections of the basal ganglia**

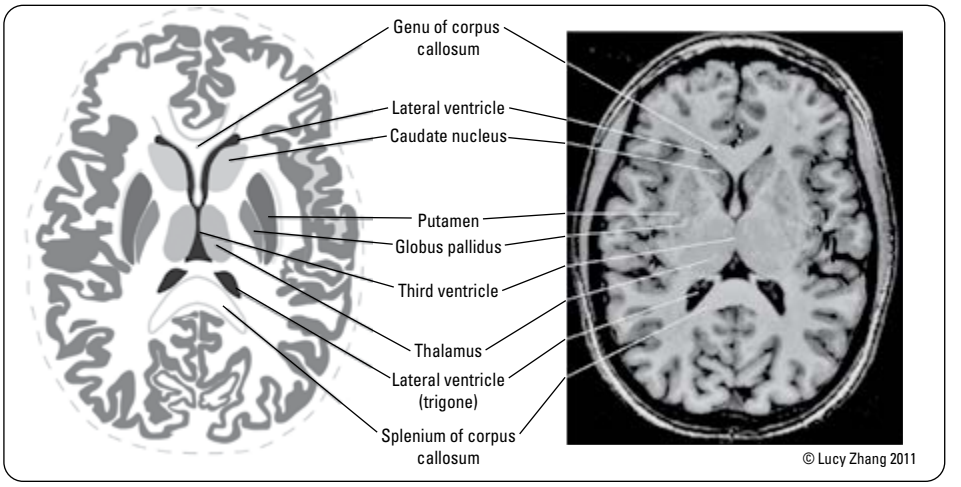

**Figure 21. Horizontal section of basal ganglia**

# Overview of Movement Disorders

**Table 16. Movement Disorder Definitions**

| | |
|---|---|
| **Akathisia** | Subjective generalized restlessness relieved by voluntary stereotypic movements (e.g. squirming) |
| **Asterixis** | Transient loss of muscle tone (negative myoclonus) |
| **Athetosis** | Slow writhing movements, especially distally |
| **Bradykinesia** | Slow and/or small amplitude of movements |
| **Chorea** | Brief, unpredictable, irregular movements, flowing from one body part to another; can appear purposeful in milder forms |
| **Dysdiadochokinesia** | Inability to smoothly perform rapidly alternating movements |
| **Dyskinesia** | Any involuntary movement, but the term is often used to describe the stereotypical movements that come with long-term neuroleptic use (tardive dyskinesia) |
| **Dystonia** | Co-contraction of agonist and antagonist muscles causing sustained twisting movements which can be tonic (dystonic postures) or phasic (dystonic movements) |
| **Freezing** | Episodes of halted motor action, especially during repetitive actions (e.g. walking) |
| **Ballism** | Large-amplitude, involuntary, flinging movements that are most commonly unilateral (hemiballism) |
| **Myoclonus** | Brief muscle group contraction that is either focal, segmental, or generalized |
| **Myokymia** | Spontaneous, fine, fascicular contraction of muscle |
| **Tachykinesia** | Acceleration of movements e.g. accelerated walking (festination) |
| **Tics** | Stereotyped and brief repetitive actions due to inner urge<br>Can be suppressed<br>Can be phonic (vocal) or motor |
| **Tremor** | Rhythmic and involuntary antagonistic muscle contractions |

In some cases, dystonias may occur only during voluntary movement and sometimes only during specific activities, such as writing, chewing, or speaking (task-specific dystonia)

Hemiballismus is most often due to a vascular lesion of the contralateral subthalamic nucleus

Myoclonus is often stimulus-sensitive as it can be induced by sudden noise, movement, light, visual threat, or pinprick

# Movement Disorders

## Differential Diagnoses

### 1. Tremor

**Table 17. Approach to Tremors**

| | Resting | Action-Postural | Action-Intention |
|---|---|---|---|
| **Body Part** | UE>jaw>LE>head | UE>head>LE>tongue | UE>voice>LE |
| **Characteristics** | 3-7 Hz pill rolling | 6-12 Hz fine tremor | <5 Hz coarse tremor |
| **Worse with Associated Sx** | Rest while concentrating<br>"TRAP" | Sustained posture (outstretched arms)<br>± Autosomal dominant FHx | Finger to nose<br>Cerebellar findings |
| **DDx** | PD, Parkinsonism, Wilson's disease, mercury poisoning | Physiologic, essential, hyperthyroidism, hyperglycemia, heavy metal poisoning, CO poisoning, drug toxicity, sedative/alcohol withdrawal | Cerebellar disorders, Wilson's disease, MS, anticonvulsants, alcohol, sedatives |
| **Treatment** | Carbidopa-levodopa (Sinemet®), surgery, DBS | Propranolol, primidone, topiramate, and other anticonvulsants | Treat underlying cause |

In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson's disease), and CT/MRI (cerebellar disease) as indicated by type of tremor

Most of the time, essential tremor does not need treatment

**Alcohol**
- Dampens essential tremor
- Potentiates intention tremor during abstinence (delirium tremens)
- Does not improve resting tremor of PD

**2. Chorea:** Huntington's disease (HD), HD-like syndromes, neuroacanthocytosis, SLE, APLA syndrome, Wilson's disease, CVD, tardive dyskinesia, senile chorea, Sydenham's chorea, pregnancy chorea (chorea gravidarum)

Most common cause of chorea is drug therapy for PD (levodopa induced dyskinesias)

**3. Dystonia**
- **primary dystonia**: familial, sporadic (torticollis, blepharospasm, writer's cramp)
- **dystonia-plus syndromes:** dopa-responsive dystonia, myoclonus-dystonia
- **secondary dystonia:** thalamotomy, stroke, CNS tumour, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
- **heredodegenerative dystonias:** Parkinsonian disorders, Wilson's disease, Huntington's disease

**4. Myoclonus**
- **physiologic myoclonus:** hiccups, nocturnal myoclonus
- **essential myoclonus:** myoclonus-dystonia with minimal or no occurrence of dystonia
- **epileptic myoclonus**
- **symptomatic myoclonus**
- **degenerative disorders:** Wilson's disease, Huntington's disease, corticobasal degeneration
- **infectious disorders:** CJD, viral encephalitis, AIDS-dementia complex
- **metabolic disorders:** drug intoxication/withdrawal, hypoglycemia, hyponatremia, hyperglycemic hyperosmolar syndrome, hepatic encephalopathy, uremia, hypoxia
- **focal brain damage:** head injury, stroke, mass

**Palatal myoclonus** can result from lesion to the Dentato-Rubro-Olivary tract and is associated with an audible clicking and tremor of other facial muscles

# Parkinson's Disease

## Etiology
- sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- familial (10%): autosomal dominant α-synuclein or LRRK2 mutations, autosomal recessive parkin, PINK1, or DJ-1mutation (juvenile onset)
- MPTP (neurotoxin)

## Epidemiology
- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neurodegenerative disorder, after Alzheimer's disease
- mean age of onset is 60 yr

## Associated Factors
- risk: family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

## Pathophysiology
- loss of dopaminergic neurons in pars compacta of substantia nigra → decreased dopamine in striatum → 1. disinhibition of the indirect pathway, and 2. decreased activation of the direct pathway → increased inhibition of cortical motor areas
- α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

## Clinical Features
- diagnosis is based on clinical features:
  1. Negative motor
     - bradykinesia: slow, small amplitude movements, fatigue from rapid alternating movements, difficulty initiating movement
  2. Positive motor
     - resting tremor: typically 4-6 Hz "pill-rolling" tremor, especially in hands
     - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
  3. Asymmetric onset of tremor, rigidity, bradykinesia
  4. Progressive course
  - other signs and symptoms of Parkinson's disease include:
    - related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
    - freezing of gait: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
    - postural instability: late finding presenting as falls
    - cognition: bradyphrenia (slow to think/respond), dementia (late finding)
    - behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
    - autonomic: constipation, urinary retention, sexual dysfunction, orthostatic hypotension, clinostatic hypertension

## Treatment
- **pharmacologic**
  - mainstay of treatment: levodopa/carbidopa (Sinemet®) or levodopa/benserazide (Prolopa®)
  - Levodopa is a dopamine precursor; carbidopa and benserazide decrease peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
    - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration ("wearing-off"), random oscillations of on-off symptoms
    - major adverse effect of levodopa is dyskinesia
  - treatment of early PD: dopamine agonists, amantadine, MAOI
  - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), catechol-O-methyltransferase inhibitors
- **surgical**
  - thalamotomy
  - pallidotomy
  - deep brain stimulation (thalamic, pallidal, subthalamic)
- **psychiatric**
  - SSRIs first line
  - TCAs (beware fall risk, cognitive impairment, and worsening symptoms of Parkinson's disease)

**Key Parkinsonian Features**

**TRAP**
**T**remor (resting)
**R**igidity
**A**kinesia/bradykinesia
**P**ostural instability

**2015 MDS Clinical Diagnostic Criteria for PD**
**"Clinically Established PD" requires:**
- Cardinal Parkinsonism Manifestations: Bradykinesia with either rest tremor or rigidity
- 2 or more supportive criteria (clear and dramatic beneficial response to dopaminergic therapy, levodopa-induced dyskinesia, rest tremor of a limb, olfactory loss/cardiac sympathetic denervation on MIBG scintigraphy)
- No absolute exclusion criteria and no red flags (see full diagnostic criteria - Mov Disord 2015;30:1591-601)

**Consider an Alternative Diagnosis if Atypical Parkinsonism**
- Poor response to levodopa
- Abrupt onset of symptoms
- Rapid progression
- Early falls
- Early autonomic dysfunction
- Symmetric symptoms at onset
- Early age of onset (<50 yr)
- Early cognitive impairment
- FHx of psychiatric/dementing disorders
- Recent diagnosis of psychiatric disease
- History of encephalitis
- Unusual toxin exposure
- Extensive travel history

# Other Parkinsonian Disorders

- **NCD with Lewy bodies** (see *Behavioural Neurology*, N20)
- **progressive supranuclear palsy:** tauopathy with limited vertical gaze (downgaze more specific) that can be overcome by the oculocephalic reflex, early falls, wide-based unsteady gait, axial rigidity; and akinesia, dysarthia, and dysphagia
- **corticobasal syndrome:** tauopathy with varied presentations but classically presenting with unilateral parkinsonism, dystonia/myoclonus, and apraxia ± "alien limbs" phenomenon; ± progressive non-fluent aphasia

**Dopamine Agonist Therapy in Early Parkinson's Disease**
Cochrane DB Syst Rev 2009;2:CD006564
**Study**: Meta-analysis of trials of dopamine agonists in early Parkinson's disease.
**Results**: Twenty-nine trials were included (n=5247). Dopamine agonists were found to have decreased motor side effects (dyskinesia [OR 0.51], dystonia [OR 0.64], motor fluctuations [OR 0.75]), but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation [OR 1.59], hallucinations [OR 1.69], dizziness [OR 1.45]).
**Conclusion**: Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.

- **multiple system atrophy:** synucleinopathy presenting as either cerebellar predominant (MSA-C, previously olivopontocerebellar atrophy) or parkinsonism predominant (MSA-P, previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- **vascular parkinsonism:** multi-infarct presentation with gait instability and lower body parkinsonism; less likely associated with tremor

# Huntington's Disease

### Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in huntingtin (HTT) gene on chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

### Epidemiology
- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr, but varies with degree of anticipation from 5-70 yr

### Clinical Features
- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to major NCD, psychosis, and chorea
  - major NCD: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence
- Juvenile-onset HD (Westphal variant) characterized by Parkinsonism, dystonia, rigidity, seizures

### Investigations
- MRI
  - enlarged ventricles, atrophy of cerebral cortex, and caudate nucleus
- genetic testing
  - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
  - CAG repeats (>28) on chromosome 4p16.3 that encodes the protein huntingtin

### Treatment
- no disease-altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

# Dystonia

### Epidemiology
- 3rd most common movement disorder after Parkinson's disease and essential tremor

### Clinical Features
- sustained or intermittent twitching movements caused by co-contraction of agonist and antagonist muscles
- symptoms exacerbated by fatigue, stress, and emotions; relieved by sleep or specific tactile/proprioceptive stimuli ('geste antagoniste', e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalized if younger onset or leg dystonia

### Treatment
- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), or benzodiazepines, dopamine depletors (tetrabenazine); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotactic thalamotomy (unilateral dystonia), posteroventral pallidotomy, or DBS

# Tic Disorders

### Definition
- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - onset is <18 yr
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

### Clinical Classification
- **Tourette's Syndrome:** multiple motor and ≥1 vocal tics that have persisted for >1 yr since onset
- **persistent (chronic) motor or vocal tic disorder:** single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for >1 yr since onset

- **provisional tic disorder:** single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- **other specified or unspecified tic disorder:** symptoms characteristic of a tic disorder but do not meet full criteria
- **secondary tic disorders:** encephalitis, CJD, Sydenham's chorea, head trauma, drugs, mental retardation syndromes

### Tic Types
- simple tics: short duration (msec)
- complex tics: longer (seconds), more purposeful and often include a combination of simple tics
- motor tics
  - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  - dystonic: bruxism (grinding teeth), abdominal tension, sustained mouth opening
  - complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics
  - simple: blowing, coughing, grunting, throat clearing
  - complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

### Treatment
- dopamine blockers, dopamine depletors (tetrabenazine), clonidine, clonazepam, or DBS

## Tourette's Syndrome (Gilles de la Tourette Syndrome)

### Definition According to DSM V
1. Presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. Tics may wax and wane in frequency but have persisted >1 yr since first tic onset (with no tic-free periods >3 mo)
3. Onset is <18 yr
4. Not due to effect of a substance or another medical condition

### Epidemiology
- estimated prevalence among adolescents 3-8 per 1000 school-age children; M:F = 2:1-4:1

### Signs and Symptoms
- tics: wide variety that wax and wane in type and severity; can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
  - can be worsened by anxiety, excitement, and exhaustion; improved by calm, focused activities
- psychiatric: compulsive behaviour (associated with OCD and ADHD), hyperactive behaviour, 'rages', sleep-wake disturbances, or learning disabilities

### Treatment
- same as tics (dopamine blockers, dopamine depletors, clonidine, clonazepam, DBS)

### Prognosis
- typically begins between ages 4-6
- peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by age 18)
- tic symptoms, however, can manifest similarly in all age groups and across the lifespan

# Cerebellar Disorders

### Clinico-Anatomic Correlations
- **vermis:** trunk/gait ataxia
- **cerebellar lobe (i.e. lateral):** rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

### Symptoms and Signs of Cerebellar Dysfunction
- nystagmus: observe during extraocular movement testing (most common is gaze-evoked nystagmus)
- dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/slurred speech on spontaneous speech
- ataxia: broad-based, uncoordinated, lurching gait
- dysmetria: irregular placement during voluntary movement of limb or eye
- dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation-supination task)
- postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
- intention tremor: typically orthogonal to intended movement, and increases as target is approached
- hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
- pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres), pendular reflexes at triceps
- rebound phenomenon: overcorrection after displacement of a limb
- hypermetric saccades

# Wernicke-Korsakoff Syndrome

- see Psychiatry, PS27
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

# Cerebellar Ataxias

### Congenital Ataxias
- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

### Hereditary Ataxias
- **autosomal recessive:** Friedrich's ataxia, ataxia with oculomotor apraxia, ataxia telangiectasia, vitamin E deficiency
  - Friedrich's ataxia: prevalence 2/100,000; typical onset between 8-15 yr
    - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
    - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- **autosomal dominant:** most commonly spinocerebellar ataxias (SCAs); 30+ types, most commonly due to CAG repeats
  - signs: ataxia and dysarthria, chorea, polyneuropathy, pyramidal and/or extrapyramidal features, dementia

### Acquired Ataxias
- neurodegeneration: e.g. multiple system atrophy
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson's, thiamine deficiency, vitamin E deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

# Vertigo

- see Otolaryngology, OT12

# Motor Neuron Disease

## Amyotrophic Lateral Sclerosis (Lou Gehrig's Disease)

### Definition
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

### Etiology
- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

### Pathology
- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

### Epidemiology
- 5/100,000; incidence increases with age

### Clinical Features
- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles, bowel, bladder, sphincters

### Investigations
- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

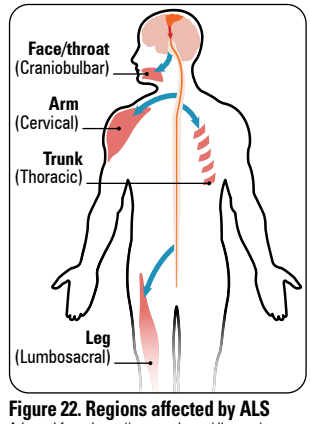

**Figure 22. Regions affected by ALS**
Adapted from: https://www.mda.org/disease/amyotrophic-lateral-sclerosis/signs-and-symptoms and labels: ALS and Other Motor Neuron Diseases (2017) Lecture by Dr. Aaron Izenberg

The only interventions shown to extend survival in ALS are riluzole and use of BiPAP. Edavarone in early ALS can decrease functional decline

**Red Flags Inconsistent with ALS**
Sensory Sx, predominant pain, bowel or bladder incontinence, cognitive impairment, ocular muscle weakness

### Treatment
- riluzole (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine (Zanaflex®), regular exercise, and physical therapy
  - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular Botox® (rare)
  - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
- edaravone is FDA and Health Canada approved; reduces functional decline by 33% in early stage ALS
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. percutaneous endoscopic gastrostomy tube), rehabilitation (PT, OT, SLP), psychosocial support

### Prognosis
- median survival 3 yr; death due to respiratory failure

**Denervation on EMG**
Fibrillations, positive sharp waves, complex repetitive discharges

**Reinnervation on EMG**
Increased amplitude and duration of motor units

## Other Motor Neuron Diseases

- degenerative
  - **progressive muscular atrophy** (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS; 5-10% of patients in ALS centres
  - **primary lateral sclerosis** (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal, variable disability; 5-10% of patients in ALS centres
  - **spinal muscular atrophy**: pediatric disease with symmetric LMN symptoms
- infectious
  - post-polio syndrome
  - West Nile infection: residual asymmetric muscle weakness, atrophy

## Peripheral Neuropathies

### Diagnostic Approach to Peripheral Neuropathies
1. Differentiate: motor vs. sensory vs. autonomic vs. mixed
2. Pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. Temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. History: PMH, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. Detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

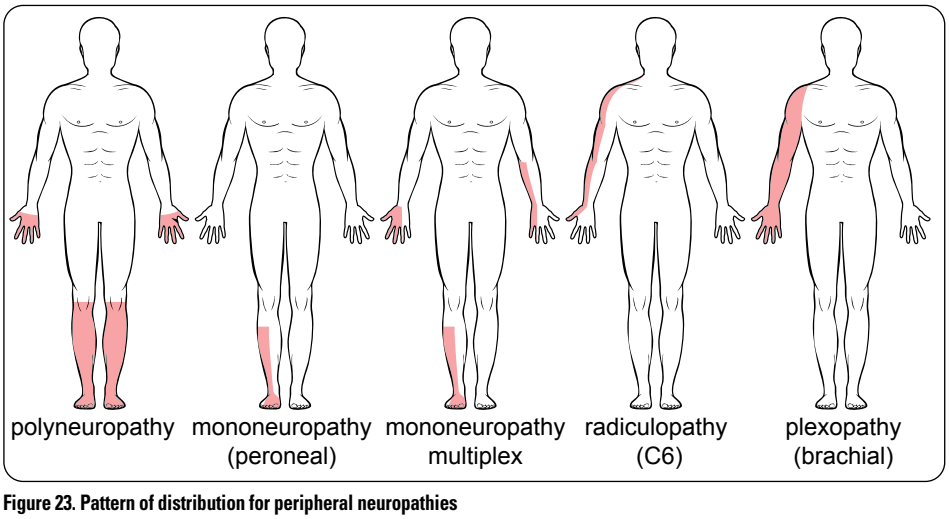

**Figure 23. Pattern of distribution for peripheral neuropathies**

**Diabetic Neuropathies**
- Peripheral neuropathy: pain or loss of sensation in a glove and stocking distribution (hands and feet affected before arms and legs)
- Autonomic: anhidrosis, orthostatic hypotension, impotence, gastroparesis, bowel and bladder dysfunction
- Mononeuropathy multiplex: nerve infarct or compression
- Cranial neuropathy: CN III (pupil sparing) > IV > VI
- Lumbosacral plexopathy

### Classification
- **monoradiculopathy**: dermatomal deficit due to single nerve root lesion
  - due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- **polyradiculopathy**: multiple dermatome deficits due to multiple nerve root lesions (e.g. one type is cauda equina syndrome (lumbosacral roots))
- **plexopathy**: deficit matching distribution of a nerve plexus
  - **brachial plexopathy**
    - upper (C5-C7): LMN Sx of shoulder and upper arm muscles (Erb's palsy)
    - lower (C8-T1): LMN Sx and sensory Sx of forearm and hand (Klumpke's palsy)
    - DDx: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome (i.e. cervical rib)
  - **lumbosacral plexopathy** (rare, especially unilateral)
    - DDx: idiopathic neuritis, infarction (i.e. DM), compression

**Tinel's Sign**
Tap lightly over the median nerve at the wrist; the patient's symptoms of carpal tunnel will be elicited in a positive test

**Phalen's Test**
Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited

**DDx of Demyelinating Neuropathy**
GBS, CIDP, paraproteinemia, diphtheria, amiodarone, Charcot-Marie-Tooth, storage diseases, pressure palsy predisposition, paraneoplastic

- **mononeuropathy**: single nerve deficit
  - **carpal tunnel syndrome** (most common): compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel's sign, Phalen's test, thenar muscle wasting, sensory deficit
    - EMG/NCS: slowing at wrist (both motor and sensory)
    - etiology: entrapment, pregnancy, DM, gammopathy, rheumatoid arthritis, thyroid disease
  - **Bell's palsy** (most common cranial neuropathy): see Otolaryngology, OT22
  - **Entrapment/compression**: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
- **mononeuropathy multiplex**: deficit affecting multiple discrete nerves (asymmetric)
  - must rule out vasculitis or collagen vascular disease; consider MMN (multifocal motor neuropathy) or MADSAM (multifocal acquired demyelinating sensory and motor neuropathy)
- **polyneuropathy**: symmetrical distal stocking-glove pattern
  - symmetrical distal sensorimotor deficit affecting longest fibres first (stocking-glove distribution), hypotonia; progression of dysesthesia earlier and weakness later
  - etiology: DM (most common), renal disease, substances, toxins, genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia
  - **chronic inflammatory demyelinating polyneuropathy (CIDP)**
    - chronic relapsing sensorimotor polyneuropathy with increased protein in CSF and demyelination (shown on EMG/NCS)
    - course is fluctuating, in contrast with the acute onset of GBS
    - treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased velocity on NCS

Ototoxic drugs (e.g. aminoglycosides) should not be given to diabetics
Sensory neuropathy of the feet prevents them from adequately compensating for loss of vestibular function

IVIG and plasmapheresis lead to more rapid improvement, less intensive care, and less ventilation, but do not change mortality or relapse rate

**Table 18. Differential Diagnosis of Symmetric Polyneuropathy**

| | Etiology | Mechanism | Course | Modalities | Investigations |
|---|---|---|---|---|---|
| **Vascular** | PAN | Ischemic | Chronic | S/M | See Rheumatology, RH20 |
| | SLE | Ischemic | Chronic | S/M | See Rheumatology, RH11 |
| | RA | Ischemic | Chronic | S/M | See Rheumatology, RH8 |
| **Infectious** | HIV | Axonal/demyelination | Chronic | S/A | HIV serology |
| | Leprosy | Infiltrative | Acute | S/A | Leprosy serology<br>Nerve biopsy |
| | Lyme | Axonal/demyelination | Chronic | M | Lyme serology |
| **Immune** | GBS | Demyelination | Acute | M | LP (↑ protein; no ↑ cells) |
| | CIDP | Demyelination | Chronic | S/M | LP (↑ protein) |
| **Hereditary** | HMSN | Axonal/demyelination | Chronic | S/M | Genetic testing |
| **Neoplastic** | Paraneoplastic | Axonal/demyelination | Chronic | S/M | Paraneoplastic antibodies |
| | Myeloma | Axonal/demyelination | Chronic | S/M | SPEP<br>Skeletal bone survey |
| | Lymphoma | Axonal | Chronic | M | SPEP<br>Bone marrow biopsy |
| | Monoclonal gammopathy | Demyelination | Chronic | S/M | SPEP<br>Bone marrow biopsy |
| **Toxin** | EtOH | Axonal | Sub-acute | S/M | GGT, MCV |
| | Heavy metals (i.e. lead) | Axonal | Sub-acute | S/M | Urine heavy metals |
| | Medications | Axonal | Sub-acute | S/M | Drug levels |
| **Metabolic** | DM | Ischemic/axonal | Chronic | S/A | Fasting glucose, HbA1c, 2 h OGTT |
| | Hypothyroidism | Axonal | Chronic | S/M | TSH, T3, T4 |
| | Renal failure | Axonal | Chronic | S/A | Electrolytes, Cr, BUN |
| **Nutritional** | B12 deficiency | Axonal | Sub-acute | S/M | Vitamin B12 |
| **Other** | Porphyria | Axonal | Sub-acute | M | Urine porphyrins |
| | Amyloid | Axonal | Sub-acute | S | Nerve biopsy |

A = autonomic; CIDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; OGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPEP = serum protein electrophoresis

**Evaluation of Distal Symmetric Polyneuropathy: Role of Laboratory and Genetic Testing**
Neurology 2009;72:185-92
**Screening Lab Tests**: Blood glucose, serum B12 with metabolites, serum protein immunofixation electrophoresis.
**Genetic Testing**: Indicated for cryptogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CMT1A duplication/deletion and Cx32 mutations.

### Guillain-Barré Syndrome

- **definition**: acute rapidly evolving demyelinating inflammatory polyradiculoneuropathy that often starts in the distal lower limbs and ascends
- **etiology**
  - autoimmune attack and damage to peripheral nerve myelin
  - sometimes preceded by viral/bacterial infections
- **signs and symptoms**
  - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
  - motor: weakness starting distally in legs, areflexia
  - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- **investigations**
  - CSF: albuminocytologic dissociation (high protein, normal WBC)
  - EMG/NCS: conduction block, differential or focal (motor > sensory) slowing, decreased F-wave, sural sparing
- **treatment**
  - IVIG or plasmapheresis, pain management, monitor vitals and vital capacity
- **prognosis**
  - peak of symptoms at 2-3 wk, resolution at 4-6 wk
  - 5% mortality (higher if require ICU); up to 15% have permanent deficits

GBS is a neurological emergency due to risk of imminent respiratory failure

The most common antecedent infection in GBS is *Campylobacter jejuni*

**Miller-Fischer Variant of GBS – Triad**
- Ophthalmoplegia
- Ataxia
- Areflexia

# Neuromuscular Junction Diseases

## Clinical Approach to Disorders of the Neuromuscular Junction

**Table 19. Common Disorders of the Neuromuscular Junction**

| | Myasthenia Gravis | Lambert-Eaton | Botulism |
|---|---|---|---|
| **Ocular/Bulbar Paresis** | + | – | ++ (early) |
| **Limb Weakness** | + | + | + |
| **Fatigability** | + | + | + |
| **Post-Exercise Enhancement** | – | + | + |
| **Reflexes** | N | ↓ | ↓ |
| **Anticholinergic Sx** | – | + | ++ |
| **Sensory Sx** | – | – | – |
| **Associated Conditions** | Thymoma | Small cell carcinoma | GI S&S |
| **Repetitive EMG Stimulation** | Decremental response | Incremental response | ↑ (rapid stimulation)<br>↓ (slow stimulation) |

**Neuromuscular Junction Disease**
- Diseases of the neuromuscular junction typically feature prominent fatigability
- Fatigability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG)
- Muscle weakness due to fatigability will improve with rest or ice

# Myasthenia Gravis

### Etiology and Pathophysiology

- progressive autoimmune disorder due to anti-ACh or anti-muscle specific kinase antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

### Epidemiology

- bimodal age of onset – 20s (mostly women) and 60s (mostly men)

### Clinical Features

- fatigable, symmetric, or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

### Investigations

- edrophonium (Tensilon®) test - assess for improvement over 2 min following edrophonium injection
- EMG
  - repetitive stimulation → decremental response
  - single fibre electromyography shows increased jitter (80-100% sensitivity)
- spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
- anti-AChR antibody assay (70-80% sensitivity); anti-MuSK antibody may be used if seronegative for anti-AChR antibody
- CT/MRI to screen for thymoma/thymic hyperplasia

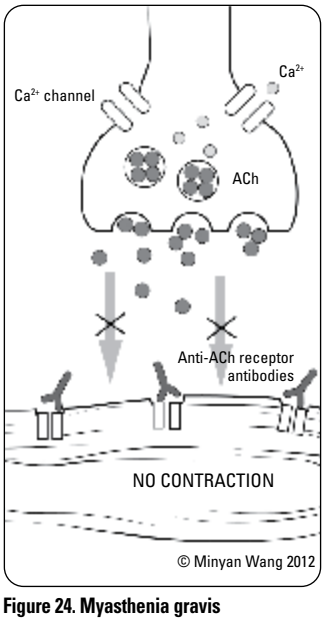

**Figure 24. Myasthenia gravis**

### Treatment
- first line treatment: acetylcholinesterase inhibitors (e.g. pyridostigmine)
- corticosteroids (e.g. prednisone): mainstay of treatment if acetylcholinesterase inhibitors not effective
- immunosuppression (e.g. azathioprine, cyclophosphamide, mycophenolate): can be used as steroid-sparing therapy
- short-term immunomodulation (e.g. IVIG and plasmapheresis): for crisis
- thymectomy: option in non-thymomatous MG; 85% remission rate

### Prognosis
- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

Tensilon® is a drug that inhibits acetylcholinesterase. It improves muscle function immediately in myasthenia gravis, but not in a cholinergic crisis.This test is infrequently used; when performed, a crash cart should be nearby as respiratory difficulty and/or bradycardia may occur

## Lambert-Eaton Myasthenic Syndrome

### Etiology and Pathophysiology
- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcinoma of the lung

### Clinical Features
- weakness of skeletal muscles without sensory or coordination abnormalities, proximal and lower muscles more affected
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and ocular muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

### Investigations
- edrophonium test → no response
- EMG
  - rapid (>10 Hz) repetitive stimulation → incremental response
  - post-exercise facilitation → incremental response with exercise
- screen for malignancy, especially small cell lung cancer

### Treatment
- tumour removal
- ACh modulation
  - increased ACh release (3,4-diaminopyridine)
  - decreased ACh degradation (pyridostigmine)
- immunomodulation - steroids, plasmapheresis, IVIG

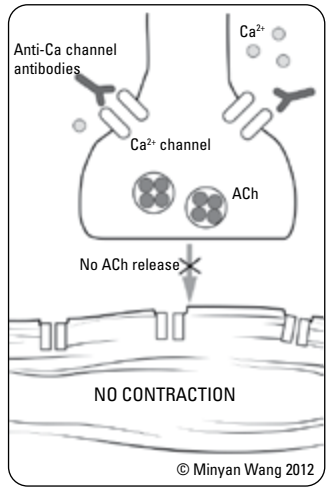

**Figure 25. Lambert-Eaton myasthenic syndrome (LEMS)**

## Botulism

### Etiology and Pathophysiology
- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which can enter through wounds or by ingestion
- infantile botulism is the most common form and is usually from ingestion of honey or corn syrup

### Clinical Features
- occur 6-48 h after ingestion
- CN paralysis: ptosis, extraocular muscle weakness, dilated poorly reactive pupils, dysarthria, jaw weakness, dysphagia
- autonomic dysfunction: nausea, orthostatic hypotension, constipation (paralytic ileus), bladder distension
- anticholinergic symptoms: dry mouth, constipation, urinary retention
- spreads to trunk and limbs: symmetric weakness with paralysis and absent/decreased deep tendon reflexes
- pattern of paresis often starts with GI symptoms → extraocular muscle weakness → dysphagia → limbs and respiratory involvement; associated with dry mouth
- rarely respiratory distress, potentially advancing to respiratory failure

### Investigations
- blood test for toxin, stool culture
- CT/MRI to rule out stroke, lesion (normal in botulism)

### Treatment
- botulinum anti-toxin – good prognosis with prompt treatment
- supportive therapy as required

# Myopathies

## Clinical Approach to Muscle Diseases

**Table 20. Myopathies**

| | Etiology | Key Clinical Features | Key Investigations |
|---|---|---|---|
| **Inflammatory** | Polymyositis (see Rheumatology , RH15) | Myalgias<br>Pharyngeal involvement | ↑ CK<br>Biopsy: endomysial infiltrates, necrosis |
| | Dermatomyositis (see Rheumatology , RH15) | Myalgias<br>Characteristic rashes<br>Can be paraneoplastic | ↑ CK<br>Biopsy: perifascicular atrophy |
| | Sarcoidosis | See Respirology, R15 | ACE level<br>Biopsy: granulomas |
| | Inclusion body myositis | Weak quadriceps and deep finger flexors | ↑ CK<br>Biopsy: inclusion bodies |
| **Endocrine** | Thyroid (↑ or ↓)<br>Cushing's syndrome<br>Parathyroid (↑ or ↓) | See Endocrinology, E23 | TSH<br>Serum cortisol<br>Calcium panel |
| **Toxic** | Medication | Medication or toxin history | Toxicology screen |
| | Critical illness myopathy | ICU patient<br>Hx steroids and nondepolarizing paralyzing agents<br>Failure to wean from ventilation | Biopsy: selective loss of thick myosin filaments |
| **Infectious** | Parasitic, bacterial, or viral | Myalgias<br>Inflammatory myopathy | ↑ myoglobin |
| **Hereditary Dystrophy** | Duchenne (see Medical Genetics, MG8) | Early onset (Duchenne and Becker) | Dystrophin analysis: absent |
| | Becker | Progressive proximal muscle weakness<br>Calf pseudohypertrophy | Dystrophin analysis: abnormal |
| | Myotonic dystrophy | Distal myopathy<br>Myotonia<br>Genetic anticipation | Genetic testing |
| **Hereditary Metabolic** | McArdle's | Exercise-related myalgias, cramping, and myoglobuminuria | ↑ lactate<br>↑ serum/urinary myoglobin post-exercise |
| **Hereditary Periodic Paralysis** | "Channelopathy" | Episodic weakness<br>Normal between attacks | Normal, ↑ or ↓ K+ |
| **Hereditary Mitochondrial** | MERRF | Myoclonus, generalized seizures, dementia, myopathy | Biopsy: ragged red fibres<br>Increased lactate |
| | MELAS | Pediatric onset, stroke-like symptoms, episodic vomiting, dementia | |
| | Kearns Sayre | Progressive ophthalmoplegia, retinal pigment degeneration, cardiac conduction abnormalities | |

MELAS = mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF = mitochondrial encephalomyopathy with ragged red fibres
ACE = acetylcholinesterase; CK = creatine kinase

Myopathies are characterized by prominent symmetric proximal weakness and absent sensory changes

**Good Questions to Assess Proximal Weakness**
- Legs: climbing stairs, stand from sit
- Arms: reach above head, wash hair

**Common Medications that Cause Myopathy:** steroids, statins, anti-retrovirals, thyroxine, fibrates, cyclosporine, ipecac
**Common Drugs that Cause Myopathy:** ethanol, cocaine, heroin

# Myotonic Dystrophy

### Etiology and Pathophysiology
- unstable trinucleotide (CTG) repeat in myotonic dystrophy kinase gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms, autosomal dominant

### Epidemiology
- most common adult muscular dystrophy, prevalence 3-5/100,000

### Clinical Features
- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1° heart block; atrial arrhythmias)
  - respiratory: hypoventilation 2° to muscle weakness
  - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
  - other: DM, infertility, testicular atrophy
  - EMG: subclinical myotonia – long runs with declining frequency and amplitude

### Treatment
- management of myotonia: phenytoin

### Prognosis
- no cure, progressive, death usually around 50 yr

# Pain Syndromes

## Approach to Pain Syndromes

### Definitions
- **nociceptive pain**: pain arising from normal activation of peripheral nociceptors
- **neuropathic pain**: pain arising from direct injury to neural tissue, bypassing nociceptive pathways
- **spontaneous pain**: unprovoked burning, shooting, or lancinating pain
- **paresthesia**: spontaneous abnormal non-painful sensation (e.g. tingling)
- **dysesthesia**: evoked pain with inappropriate quality or excessive quantity
- **allodynia**: a dysesthetic response to a non-noxious stimulus
- **hyperalgesia**: an exaggerated pain response to a noxious stimulus

### Non-Pharmacological Management
- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

### Medical Pain Control
- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxybenzamine), α2-adrenergic agonists (clonidine)

### Surgical Pain Control
- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

## Neuropathic Pain

### Definition
- pain resulting from a disturbance of the CNS or PNS

### Epidemiology
- affects up to 6% of people (2 million Canadians)

- Pinprick sensation mediated by Aδ fibres
- Pain due to tissue damage is mediated by C fibres

**WHO Pain Ladder**
- **Mild Pain**: Non-opioid (acetaminophen and/or NSAID) ± adjuvant
- **Moderate Pain**: Opioid for mild to moderate pain (codeine/oxycodone) + non-opioid ± adjuvant
- **Severe Pain**: Opioid for moderate to severe pain (morphine/hydromorphone) + non-opioid ± adjuvant

Axonal regeneration is directed by intact nerve sheaths; if the nerve sheath is damaged, axons grow without direction, become tangled, and form a neuroma. This can result in ectopic electrical impulses and neuropathic pain

### Symptoms and Signs
- hyperalgesia, allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness
- can be spontaneous or stimulus evoked, distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

### Causes of Neuropathic Pain
- **sympathetic**: CRPS
- **non-sympathetic**: damage to peripheral nerves
  - systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis, multiple sclerosis
  - nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
  - infectious: post-herpetic, HIV
  - trauma/compression: nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy
- **central**: abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS

### Treatment
- identify/treat underlying cause
- **pharmacotherapy**
  - stepwise approach (Canadian Pain Society, 2014)
    - 1st line: gabapentinoids, TCA, SNRI
    - 2nd line: tramadol, opioid analgesics
    - 3rd line: cannabinoids
    - 4th line: topical lidocaine (second line for postherpetic neuralgia), methadone, lamotrigine, lacosamide, tapentadol, botulinum toxin
- **common non-pharmacologic therapies**
  - neuropsychiatry: CBT, psychotherapy
  - rehabilitation: physiotherapy
- **surgical therapies**: dorsal column neurostimulator, DBS (thalamus)

## Trigeminal Neuralgia

### Clinical Features
- recurrent episodes of sudden onset, excruciating, unilateral, paroxysmal, shooting "electric" pain in trigeminal root territory (V3>V2>>V1)
- may have normal sensory exam
- pain lasts seconds/minutes over days/weeks; may remit for weeks/months
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

### Etiology
- classic TN: compression of CN V by tortuous blood vessel (usually superior cerebellar artery)
- 2º TN: cerebellopontine angle tumour (5%), MS (5%)
- idiopathic TN

### Epidemiology
- F>M; usually middle-aged and elderly

### Diagnosis
- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  - MRI to rule out structural lesion, MS, or vascular lesion

### Treatment
- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- for medically-refractory classic TN, consider microvascular decompression
- other neurosurgical options for medically-refractory TN: trigeminal ganglion percutaneous technique, gamma knife radiosurgery, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression
- narcotics not generally recommended

## Postherpetic Neuralgia

### Clinical Features
- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical, lumbar, sacral
- associated symptoms: impaired sleep, decreased appetite, decreased libido

**Herpes Zoster of Trigeminal Nerve**
Typically involves V1 (ophthalmic division)
**Hutchinson's Sign**
Tip of nose involvement predicts corneal involvement

### Etiology and Pathogenesis
- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

### Epidemiology
- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

### Prevention
- varicella zoster vaccine (Varivax®) in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax® or Shingrix®) reduces incidences of shingles, PHN, and other herpetic sequelae
  - Zostavax® is a live vaccine, recommended for patients ≥60 yr old
  - Shingrix® is a recombinant vaccine, recommended for patients ≥50 yr old (more efficacious than Zostavax®)

### Treatment
- medical: TCA (e.g. amitriptyline), anti-convulsants (e.g. pregabalin, gabapentin), analgesia (e.g. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  - early treatment of acute herpes zoster with antivirals (longer-acting famciclovir and valacyclovir more effective)
  - treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

## Painful Diabetic Neuropathy

- see Endocrinology, E14

### Approach
- determine if pain is neuropathic or vascular
- more likely neuropathic if pain is present at rest and improves with walking, pain is sharp/tingling, more in feet → calves

### Treatment
- Level A: pregabalin
- Level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

## Complex Regional Pain Syndromes

### Definition
- regional pain disproportionate to an inciting event (e.g. fracture, stroke), typically lasting 4-6 wk

### Diagnosis
- clinical diagnosis consistent with the Budapest Criteria:
  1. continuing regional pain disproportionate to an inciting event
  2. patient must have symptoms in 3 of the 4 categories, and must have signs in 2 of the 4 categories (a sign must be observed at the time of diagnosis):
     - sensory: hyperesthesia and/or allodynia
     - vasomotor: temperature and/or skin colour asymmetry
     - sudomotor/edema: edema, sweating changes, and/or sweating asymmetry
     - motor/trophic: decreased range of motion, motor dysfunction (weakness, tremor, dystonia) and/or trophic changes (hair, skin, nail)
  3. absence of any other diagnosis that would better explain the signs or symptoms
- bone scintigraphy ≤5 mo of symptom onset may support diagnosis (negative test does not rule it out)
- MRI may help rule out other causes of regional pain if indicated

### Classification
- CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

### Prevention
- early mobilization after injury/infarction

### Treatment
- goal of treatment is to facilitate function
- conservative treatment: education, support groups, PT, OT, smoking cessation
- medical: topical capsaicin; TCA; NSAID; tender point injections with corticosteroid/lidocaine; gabapentin/pregabalin/lamotrigine; calcitonin or bisphosphonates; oral corticosteroids
- surgical: paravertebral sympathetic ganglion blockade
- refer to pain management clinic

# Headache

- see Emergency Medicine, ER23 and Family Medicine, FM32

## Clinical Approach

- **history**
  - pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/coughing/Valsalva)
  - associated symptoms: visual changes, change in mental status, nausea/vomiting, fever, meningismus, photophobia, phonophobia, temporomandibular popping/clicking, jaw claudication, neurological symptoms
  - precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, calcium channel blockers, NSAIDs, anticoagulants), PMHx, FHx
  - red flags (possible indications for CT scan/further investigation): new-onset headache (especially if age <5 or >50), quality worse/different than previous headaches, sudden and severe ('thunderclap'), immunocompromised, fever, focal neurological deficits, trauma
- **physical exam**
  - vitals (including BP and temperature), Jolt accentuation/Kernig's/Brudzinski's, MSK examination of head and neck
  - HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
  - full neurological exam (including LOC, orientation, pupils [symmetry], and focal neurological deficits)
  - red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

## Classification

- primary
  - tension, migraine, cluster, other autonomic cephalgias, short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT)
- secondary
  - cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN, or pseudotumour cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

**Table 21. Headaches – Selected Primary Types**

| | Tension-Type | Migraine | Cluster |
|---|---|---|---|
| **Prevalence** | 70% | ~10-20% | <1% |
| **Age of Onset** | 15-40 | 10-30 | 20-40 |
| **Sex Bias** | F>M | F>M | M>F |
| **Family History** | None | +++ | + |
| **Location** | Bilateral frontal<br>Nuchal-occipital | Unilateral > bilateral<br>Fronto-temporal | Retro-orbital |
| **Duration** | Minutes-days | Hours-days | 10 min-2 h |
| **Onset/Course** | Gradual; worse in PM | Gradual; worse in PM | Daily attacks for weeks to months; more common early AM or late PM |
| **Quality** | Band-like; constant | Throbbing | Constant, aching, stabbing |
| **Severity** | Mild-moderate | Moderate-severe | Severe (wakes from sleep) |
| **Triggers/Provoking** | Depression<br>Anxiety<br>Noise<br>Hunger<br>Sleep deprivation | Noise/light<br>Caffeine/alcohol<br>Hunger<br>Stress<br>Sleep deprivation | Light<br>EtOH |
| **Palliating** | Rest | Rest | Walking around |
| **Associated Symptoms** | No vomiting<br>No photophobia | Nausea/vomiting<br>Photo/phonophobia<br>Aura | Red watery eye<br>Nasal congestion or rhinorrhea<br>Unilateral Horner's |
| **Management** | Non-pharmacological<br>Psychological counselling<br>Physical modalities (e.g. heat, massage)<br>Pharmacological<br>Simple analgesics<br>Tricyclic antidepressants | Acute Rx<br>ASA<br>NSAIDs<br>Triptans<br>Ergotamine<br>Prophylaxis<br>TCA<br>Anticonvulsants<br>Propranolol | Acute Rx<br>$O_2$<br>Sumatriptan (nasal or injection)<br>Prophylaxis<br>Verapamil<br>Lithium<br>Methysergide<br>Prednisolone |

**Table 22. Prophylactic Management of Migraine Headaches**

If CT is negative but clinically there is suspicion of SAH or meningitis, perform an LP

**Headache DDx**

**ER VISIT**
**E**ye (acute angle closure glaucoma, sinusitis)
**R**ecurrent/Chronic (migraine, tension, cluster, temporomandibular joint disease, cervical OA)
**V**ascular (SAH, ICH, temporal arteritis)
**I**nfectious (meningitis, encephalitis)
**S**ystemic (anemia, anoxia, CO, pre-eclampsia)
**I**CP (mass/abscess, HTN encephalopathy, pseudotumour cerebri)
**T**r[illegible] (concussion, SDH, epidural [illegible])

**Acute and Preventive Pharmacologic Treatment of Cluster Headache**
Neurology 2010;75:463-73
**Study**: Meta-analysis of prospective, double-blind, RCTs of pharmacologic agents for prevention or treatment of cluster headaches.
**Results**: 27 trials were included. Sumatriptan 6 mg SC, zolmitriptan nasal spray 5-10 mg, and 100% oxygen 6-12 L/min received as per level A recommendation for acute treatment. For prevention, Level B recommendations were given for intranasal civamide 100 µg daily and suboccipital steroid injections.
**Conclusion**: Sumatriptan, zolmitriptan, and mid flow oxygen are effective acute treatments for cluster headaches.

**Antiepileptics in Migraine Prophylaxis: An Updated Cochrane Review**
Cephalalgia 2015;35:51-62
**Purpose**: To review the evidence for anticonvulsants in migraine prophylactics.
**Study**: Systematic meta-analysis of 37 published and 3 unpublished prospective, controlled trials of regular use of anticonvulsants to prevent migraines and/or improve quality of life related to migraines.
**Results**: Sodium valproate and topiramate were associated with a reduction of 4 d and 1 d of headache per month, respectively, and patients taking either drug were more than 2 times as likely to experience greater than 50% reduction in headache frequency, versus placebo. Neither drug was associated with undue rates of adverse events, though higher doses of topiramate were associated with increased adverse events. There is insufficient evidence of efficacy with other antiepileptic drugs, including gabapentin, for migraine prophylaxis.
**Conclusions**: Daily sodium valproate 400 mg and topiramate 50 mg are well tolerated and effective in prophylactic treatment of migraine headache in adults.

| Class | Drug | Evidence | Contraindications | Side Effects |
|---|---|---|---|---|
| **β-blockers** | Propranolol<br>Timolol<br>Metoprolol | A<br>A<br>B | Asthma, DM (mask hypoglycemia)<br>CHF | Fatigue<br>Depression<br>Light-headedness |
| **TCA** | Amitriptyline<br>Nortriptyline | A<br>C | Heart disease, glaucoma<br>Avoid in elderly | Sedation<br>Dry mouth<br>Weight gain<br>Light-headedness |
| **CCBs** | Flunarizine | A | Depression, obesity | Weight gain, depression, PD (rare) |
| | Verapamil | B | Heart disease | Weight gain (4.5-9 kg), constipation |
| **AED** | Valproate | A | Liver, renal, pancreatic disease | Weight gain, tremor, alopecia, teratogenic: neural tube defect |
| | Topiramate + folic acid supplement | A | Renal disease | Paresthesia, weight loss, cognitive: memory loss, difficulty concentrating, renal stone (rare) |

**Table 23. Headaches – Selected Serious but Rare Secondary Types**

| | Meningeal Irritation | Increased ICP | Temporal Arteritis |
|---|---|---|---|
| **Age of Onset** | Any age | Any age | >60 yr |
| **Location** | Generalized | Any location | Temporal |
| **Onset/Course** | Meningitis: hours-days<br>SAH: thunderclap onset | Gradual; worse in AM | Variable |
| **Severity** | Severe | Severe | Variable; can be severe |
| **Provoking** | Head movement | Lying down<br>Valsalva<br>Head low<br>Exertion | Jaw claudication |
| **Associated Symptoms** | Neck stiffness<br>Photophobia<br>Focal deficits (e.g. CN palsies) | N/V<br>Focal neurological symptoms<br>Decreased level of consciousness | Polymyalgia rheumatica<br>Visual loss |

| **Management** | CT/MRI with gadolinium, LP, antibiotics for bacterial meningitis | CT/MRI and treatment to reduce pressure<br>See Neurosurgery, NS6 | Prednisone<br>See Rheumatology, RH21 |
| **Etiology** | Meningitis, SAH | Tumour, IIH, malignant HTN | Vasculitis (GCA) |

IIH = idiopathic intracranial HTN

# Migraine Headaches

## Definition (Common Migraine)

- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: nausea/vomiting, photophobia/phonophobia/osmophobia

## Epidemiology

- 18% females, 6% males; frequency decreases with age (especially at menopause)

## Etiology and Pathophysiology

- theories of migraine etiology
  - depolarizing wave of "cortical spreading depression" across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibres
  - possible association with vasoconstriction/dilation
- significant genetic contribution
- triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrites (e.g. processed meats)

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIAs and seizures)

**"Menstrual Migraine" Subtype**
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding

If patient presents to ED with severe migraine and N/V – consider treating with IV anti-emetics (chlorpromazine, prochlorperazine)

### Signs and Symptoms

- stages of uncomplicated migraine
  1. Prodrome (hours to days before headache onset)
  2. Aura
  3. Headache
  4. Postdrome
- aura
  - self-resolving symptom of focal cerebral dysfunction lasting <60 min
  - examples: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
    - examples: basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness), hemiplegic/hemisensory migraine, ophthalmoplegic migraine
  - acephalgic migraine (i.e. migraine equivalent): aura without headache

### Treatment

- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
- moderate to severe migraine
  - triptans (most effective), ergots (dihydroergotamine, dihydroergotamine mesylate [DHE])
- migraine prophylaxis: anticonvulsants (valproate, topiramate, gabapentin), TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)
- medication overuse (use of triptans/opioids/combination analgesics for ≥10 d/mo, or use of NSAIDs for ≥15 d/mo) can lead to medication-overuse headaches

**Pharmacological Treatments for Acute Migraine**
Pain 2002;97:247-57
**Study**: Meta-analysis of 54 double-blind, placebo-controlled RCTs of pharmacologic treatment of acute migraine of moderate to severe intensity (21,022 patients in total).
**Data Extraction**: Number of patients, dosing regimens, details of study design, and timing or type of rescue medication. Outcomes include headache relief at 1 and 2 h, freedom from pain at 2 h, sustained relief for 24 h, and adverse effects within 24 h.
**Main Results**: Data were available for 9 oral medications, 2 intranasal medications, and subcutaneous sumatriptan. For headache relief at 2 h, all interventions were effective except Cafergot®, with NNTs ranging from 2.0 for sumatriptan 6 mg SC to 5.4 for naratriptan 2.5 mg. The lowest NNT for oral medication was 2.6 for eletriptan 80 mg. For patients pain free at 2 h, the lowest NNT was 2.1 for sumatriptan 6 mg SC, with the lowest NNT for oral medication being 3.1 for rizatriptan 10 mg. For sustained relief over 24 h, NNT ranged from 2.8 for eletriptan 80 mg to 8.3 for rizatriptan 5 mg. Side effects could not be analyzed systematically. There were no drug-to-drug comparisons.
**Conclusion**: Overall, most treatments were effective. Subcutaneous sumatriptan and oral triptans were most effective.

# Sleep Disorders

## Overview of Sleep

### Recommendations

- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many older patients have reduced sleep as a consequence of underlying sleep disorders

### Sleep Architecture

- polysomnogram (PSG) measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

**Table 24. Sleep Stage Characteristics**

| | EEG | EOG | Muscle Tone | Other Characteristics |
|---|---|---|---|---|
| **Waking State** | Alpha waves: high frequency (8-12 Hz), low voltage | Rapid, blinking | High | |
| **Stage N1 (~5%)** | Less than 50% Alpha waves (see above), mixed with slow wave activity | Slow, roving eye movements | High, but gradually dropping | Marker for very light quality sleep or sleep disruption |
| **Stage N2 (~50%)** | K complexes (high voltage negative and positive discharges) with sleep spindles (11-16 Hz) | Still | High | |
| **Stage N3 (previously 3 and 4)/Slow Wave/ Delta Sleep (~20%)** | Delta waves: low frequency (<2 Hz), high voltage (>75 μV) | Still | Low | Homeostatic sleep<br>Reduced BP, HR, cardiac output, RR<br>Growth hormone release |
| **Rapid Eye Movement Sleep (~25%)** | Sawtooth waves, mixed frequency, low voltage | Rapid eye movements | Very low | Irregular respiration<br>Arrhythmias, heart rate variation<br>Classical dreaming state |

**Elements of Sleep History**

- Initiation of sleep
- Events prior to bed
- Lights
- Latency (estimated)
- Restless legs
- Hallucinations
- Maintaining sleep
- Number of wakeups per night
- Sleep walking/talking
- Snoring/gasping
- Dreams/nightmares
- Consequences of sleep
- Restorative
- Morning headache
- Falling asleep in inappropriate setting

# Disturbances of Alertness and Sleep

## Coma
- see Neurosurgery, NS35

## Insomnia
- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep
- **types**
  - sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
  - **secondary causes**
    - psychiatric disorders (80% of psychiatric patients): depression and anxiety (see Psychiatry, PS12, PS39)
    - neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
    - sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
    - medical conditions: pregnancy, cardiorespiratory (COPD/heart failure), gastroesophageal reflux disease, pain (arthritis, fibromyalgia, cancer)
    - drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal
- **treatment**
  - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT

**Drug Effects on Wakefulness and Sleep**
- Antihistamines associated with increased sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increases wakefulness
- Benzodiazepines reduce slow wave sleep
- Antidepressants (TCA/MAOI/SSRI) reduce REM, prolong REM latency
- Alcohol may hasten sleep onset but is associated with increased arousals

Avoid sleep medications (especially in elderly patients) due to increased risk of falls, pseudodepression, and memory loss

## Sleep Apnea
- disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)
- **epidemiology**
  - >2-4% of the population
  - correlated with obesity
  - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)
- **types**
  - obstructive sleep apnea; etiology: collapse of airway due to low muscle tone in deep and REM sleep
  - central sleep apnea: no effort to breath >10 s, etiology: heart failure, opiates, brainstem pathology, myotonic dystrophy
  - mixed apnea: starts as central, but eventually becomes obstructive
- **diagnosis**: apnea hypopnea index (AHI) or respiratory disturbance index (RDI) ≥5
- **treatment**: conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety

## Restless Leg Syndrome (RLS) and Periodic Limb Movement in Sleep (PLMS)
- urge to move accompanied by uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night; these features cannot be accounted for by another medical/behavioural condition
- RLS refers to sensation, PLMS refers to the manifestation
- **epidemiology**: 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS
- **etiology**: central (spasticity), peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use
- **treatment**
  - underlying contributors (iron and B12 supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
  - NOT recommended: levodopa/carbidopa (Sinemet®) which causes augmentation

## Narcolepsy
- **definition/clinical features**: excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic), sleep paralysis (unable to move upon wakening), hypnagogic hallucinations (vivid dreams or hallucinations at sleep onset)
- **epidemiology**: prevalence 1:2000, onset in adolescence/early adulthood; life-long disorder
- **etiology**: presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial
- **diagnosis**: based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps
- **treatment**
  - sleep hygiene and scheduled brief naps, restricted driving
  - alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
  - anticataplectic: TCAs, SSRIs, sodium oxybate

### Parasomnias
- **definition/clinical features**: unusual behaviours in sleep with clinical features appropriate to stage of sleep
- **etiology**: in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep-disordered breathing
- **diagnosis**: clinical history in children, polysomnography in adults to exclude nocturnal seizures
- **treatment**: behavioural management (safety, adequate sleep), clonazepam for REM sleep behaviour, tonsillectomy if appropriate in children

### Circadian Rhythm
- **definition/clinical features**: abnormalities based on time of day rather than sleep (e.g. jet lag, shift work)
- **diagnosis**: clinical history

# CNS Infections

- see Infectious Diseases, ID15

# Spinal Cord Syndromes

- see Neurosurgery, NS29

# Stroke

## Terminology

- **stroke**: sudden onset of neurological deficits of a vascular etiology with infarction of CNS tissue
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- **TIA**: sudden onset of neurological deficits of a vascular etiology without infarction (i.e. no imaging evidence of stroke)
  - may present with amaurosis fugax (transient monocular painless vision loss)

## Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

**1. Ischemic**
- arterial thrombosis: thrombus formation in artery (local/*in situ*)
  - large vessel: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
    - mechanism: insufficient blood flow beyond lesion (hemodynamic stroke)
    - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
  - small vessel/lacunar
    - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
    - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
- cardioembolic: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
  - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
- systemic hypoperfusion (global cerebral ischemia)
  - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
  - primarily affects watershed areas (between the major cerebral arterial territories)

**2. Hemorrhagic**
- intracerebral hemorrhage
  - mechanisms
    - hypertensive (most common): rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage; most common sites are putamen, thalamus, cerebellum, and pons
    - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaine or amphetamines)
- subarachnoid hemorrhage see Neurosurgery, NS18

**Hypertension Encephalopathy**
Acute severe HTN (typically dBP >130 or sBP >200) can cause hypertensive encephalopathy. Abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances, and change in LOC

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with magnetic resonance venography or cerebral CT venography. Treatment is typically anticoagulation with heparin initially, then warfarin eventually

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction

Blood work should only delay treatment if patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

## Stroke Syndromes According to Vascular Territory

- **ACA**: contralateral leg paresis, sensory loss, cognitive deficits (e.g. apathy, confusion, and poor judgment)
- **MCA**: proximal occlusion involves
  1. contralateral weakness and sensory loss of face and arm
  2. cortical sensory loss
  3. may have contralateral homonymous hemianopia or quadrantanopia
  4. if dominant (usually left) hemisphere: aphasia
  5. if non-dominant (usually right) hemisphere: neglect
  6. eye deviation towards the side of the lesion (away from the weak side)
- **PCA**
  1. contralateral hemianopia or quadrantanopia
  2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  3. thalamic findings: sensory loss, amnesia, decreased LOC
  4. if bilateral: cortical blindness or prosopagnosia
  5. hemiballismus
- **basilar artery**
  - proximal (usually thrombosis): impaired EOM, vertical nystagmus, reactive miosis, hemi- or quadriplegia, dysarthria, locked-in syndrome, coma
  - distal (usually embolic, i.e. top of the basilar syndrome): somnolence, memory and behaviour abnormalities, oculomotor deficit
- **PICA** (lateral medullary or Wallenberg syndrome): ipsilateral ataxia, ipsilateral Horner's, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, nausea/vomiting, dysphagia, dysarthria, hiccups
- **medial medullary infarct** (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- **lacunar infarcts** (deep hemispheric white matter; involving deep penetrating arteries of MCA, circle of Willis, basilar and vertebral arteries)
- **sensorimotor stroke**: weakness and numbness of the face/arm/leg without other cortical signs (i.e. aphasia, apraxia, visual loss)
  - pure motor hemiparesis (posterior limb of internal capsule): contralateral arm, leg, and face
  - pure sensory loss (ventral thalamic): hemisensory loss
  - ataxic hemiparesis (ventral pons or internal capsule): ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome (ventral pons or genu of internal capsule): dysarthria, facial weakness, dysphagia, mild hand weakness, and clumsiness

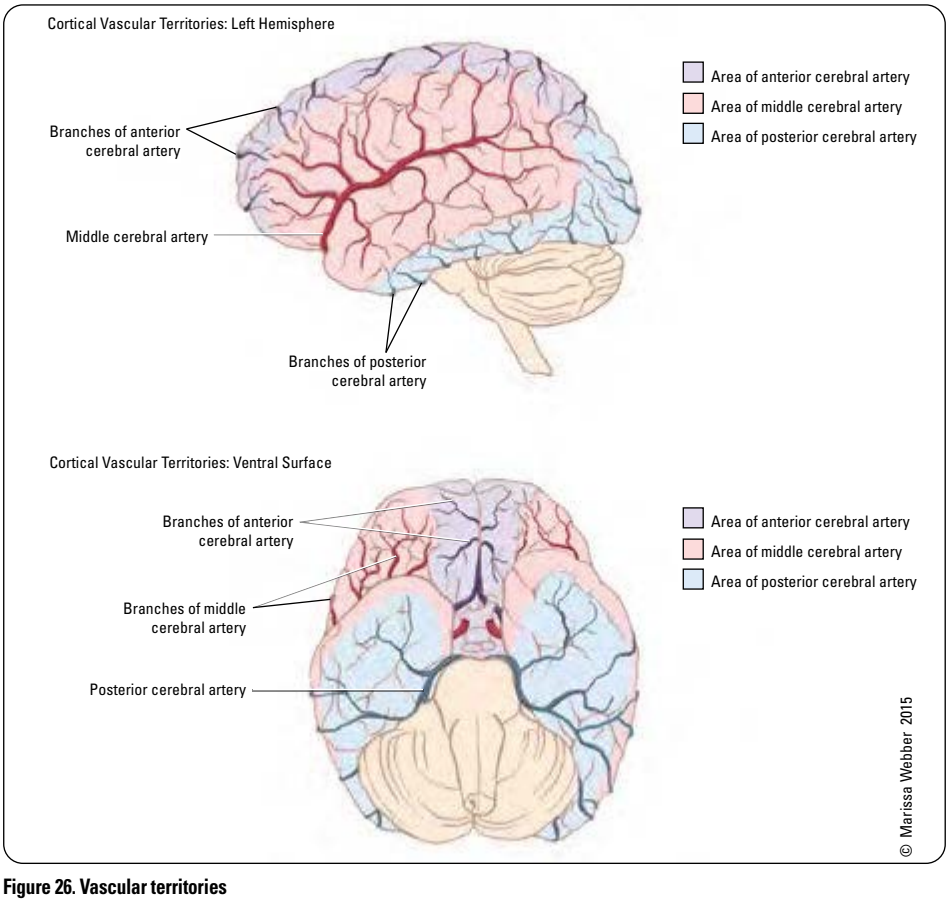

**Figure 26. Vascular territories**

Stroke mimics: drug intoxication, infections, migraines, metabolic, seizures, tumours

Suspect an alternate diagnosis if fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after stroke onset

**Oral Direct Thrombin Inhibitors or Oral Factor Xa Inhibitors for the Treatment of Deep Vein Thrombosis**
Cochrane DB Syst Rev 2015;6:CD010956
**Purpose**: To assess whether direct thrombin inhibitors or factor Xa inhibitors are effective treatment for DVTs.
**Study**: Systematic review search 1950-2015, inclusive. Results included 11 RCTs, 27,945 patients, comparing direct thrombin inhibitors or factor Xa inhibitors to standard treatment (heparin, wafarin, and similar).
**Outcome**: Recurrent DVT or PE.
**Results**: Separate meta-analyses of direct thrombin inhibitors and factor Xa inhibitors showed that each was comparable to standard treatment in terms of DVT recurrence rates. Rates of fatal or non-fatal PE, and all-cause mortality were also not significantly different. Additionally, factor Xa inhibitors had lower rates of bleeding complications than standard treatment (OR 0.57; CI 0.43 to 0.76).
**Conclusions**: New oral treatment options, including direct thrombin inhibitors and factor Xa inhibitors represent reasonable and safe alternatives for acute.

**The National Institute of Health Stroke Scale (NIHSS)** is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time
The scale uses 11 items that evaluate:
- Level of consciousness
- Visual system
- Motor system
- Sensory system
- Language abilities

Scoring (x/42):
0=no stroke
1-4=mild stroke
5-15=moderate stroke
15-20=moderate to severe stroke
21-42=severe stroke
rtPA is typically considered if score ≥6, but some stroke neurologists will administer rtPA with lower NIH stroke scale scores

# Assessment and Treatment of Ischemic Stroke

## General Assessment

- ABCs, full vital sign monitoring, capillary glucose (Accu-Chek®), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
- LOC (knows age, month; obeys commands), dysarthria, dysnomia (cannot name objects)
- gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- **history**
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- **investigations**
  - non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
  - ECG: to rule out atrial fibrillation (cardioembolic cause)
  - carotid dopplers, ECG
  - CBC, electrolytes, creatinine, partial thromboplastin time/international normalized ratio, blood glucose, lipid profile
- **imaging** (i.e. CT ± MR or CT angiography) signs of stroke
  - loss of cortical white-grey differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense MCA sign

## ACUTE STROKE MANAGEMENT

### 1. Thrombolysis

- rtPA (recombinant tissue plasminogen activator) should be given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use (see sidebar)

### 2. Anti-Platelet Therapy

- loading dose of antiplatelets at presentation of TIA or stroke if rtPA not received
  - loading dose of ASA: recommended dose 160 mg chewed
  - if patient intolerant to ASA, use another antiplatelet agent (e.g. clopidogrel 300 mg)
- ASA 81 mg daily should be continued indefinitely for secondary prevention

### 3. Acute Anti-Coagulant Therapy

- for patients with TIA or stroke and atrial fibrillation, if rtPA not received:
  - recommend IV heparin (or ensuring international normalized ratio between 2-3 if already anticoagulated on warfarin)
  - may delay initiation of oral anticoagulation depending on size of infarct and presence of petechial/frank hemorrhage

### 4. Intra-Arterial Mechanical Thrombectomy

- early thrombectomy ≤24 h since symptom onset improves outcomes in ischemic stroke with large artery occlusions of the proximal anterior circulation

## Other Acute Management Issues

- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
- prevent complications
  - NPO if dysphagia (to be reassessed by SLP)
  - DVT prophylaxis if bed-bound
  - initiate rehabilitation early

## Blood Pressure Control

- do NOT lower the blood pressure unless the HTN is severe
- antihypertensive therapy is withheld for 48-72 h (permissive hypertension) after thromboembolic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection (IV labetalol first-line if needed)
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive but their BP will improve within 1-2 d

## Etiological Diagnosis

- further investigations
  - additional neuroimaging (MRI)
  - vascular imaging: CTA/MRA/carotid dopplers
  - cardiac tests: ECG, Holter monitoring
  - correct etiological diagnosis is critical for appropriate 2º prevention strategies

**Aspect Score: 10-Point Quantitative Score to Assess Ischemic Changes on CT Scan**

- 10/10 is normal and <4/10 signifies high risk of bleed with rtPA
- Subtract 1 point for each of following structures if abnormal within the ischemic hemisphere: caudate, lentiform, insula, internal capsule, MCA 1, 2, 3, 4, 5, 6 regions

If rtPA is given at stroke onset, delay acute antiplatelet/anticoagulation treatment by 24 h

**Absolute Contraindications to rtPA**

**Hx:** improving Sx, minor Sx, seizure at stroke onset, recent major surgery or trauma (within 14 d), recent GI or urinary hemorrhage (within 21 d), recent LP or arterial puncture at noncompressible site, PMHx of ICH, Sx of SAH/pericarditis/MI, pregnancy

**P/E**: sBP ≥185, dBP ≥110, aggressive treatment to decrease BP, uncontrolled serum glucose, thrombocytopenia

**Ix:** hemorrhage or mass on CT, high INR or aPTT

**Factor Xa Inhibitors vs. Vitamin K Antagonists for Preventing Cerebral or Systemic Embolism in Patients with Atrial Fibrillation**

Cochrane DB Syst Rev 2014;8:CD008980

**Purpose**: To review the evidence comparing factor Xa inhibitors with vitamin K antagonists for prevention of embolic events in patients with atrial fibrillation.

**Study**: Inclusive systematic review search for 1950-2013. Results included 10 RCTs, 42,084 patients, follow-up from 12 wk-1.9 yr.

**Outcome**: Stroke (hemorrhagic or ischemic) and non-CNS embolic event

**Results**: Factor Xa inhibitor treatment resulted in significantly fewer embolic events than dose adjusted warfarin treatment (OR 0.81; CI 0.72 to 0.91). There was no significant difference in rate of major bleeds between factor Xa inhibitors and warfarin treatment. Furthermore, factor Xa inhibitors resulted in significantly fewer intracranial bleeds and lower all-cause mortality.

**Conclusions**: Use of factor Xa inhibitor for anti-coagulation in patients with atrial fibrillation offered better protection against embolic events than warfarin. Factor Xa inhibitors also had equal or lower rates of adverse events.

**High-Dose Atorvastatin after Stroke or Transient Ischemic Attack (SPARCL Trial)**

NEJM 2006;355:549-59

**Method**: Multicentre double-blind RCT.

**Population**: 4,731 patients with stroke or TIA within 1-6 mo before study entry, LDL 100-190 mg/dL, no coronary heart disease.

**Intervention**: 80 mg atorvastatin PO OD or placebo.

**Outcome**: First non-fatal or fatal stroke over 5 yr.

**Results**: Patients receiving atorvastatin had a lower rate of stroke (ARI 2.2%, hazard ratio 0.84; p=0.03). There was a 5 yr ARI of 3.5% (p=0.002). There was no significant change in mortality rate, but a small significant increase in the risk of hemorrhagic stroke.

**Conclusions**: High-dose atorvastatin decreases overall incidence of strokes and cardiovascular events in patients with a history of recent stroke or TIA.

**Evaluating for Occult Atrial Fibrillation – CRYSTAL AF Trial**

NEJM 2014:370;2478-86

Patients with a cryptogenic ischemic stroke or TIA and no evidence of atrial fibrillation on ECG and Holter monitoring may benefit from ambulatory cardiac monitoring with subcutaneous implantable loop recorder or external loop recorder for several weeks.

# Primary and Secondary Prevention of Ischemic Stroke

## Anti-Platelet Therapy

- primary prevention
  - no firm evidence of a protective role for antiplatelet agents in low-risk patients without a prior stroke/TIA
- secondary prevention
  - initial choice: ASA
  - if cerebrovascular symptoms while on ASA or if unable to tolerate ASA: Aggrenox® (ESPRIT trial), clopidogrel (CAPRIE trial)

## Carotid Stenosis

- primary prevention (asymptomatic)
  - carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET trial), see Vascular Surgery, VS9
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

## Atrial Fibrillation

- primary and secondary prevention with anticoagulation
  - classical risk stratification used $CHADS_2$ score (0-6), but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be anticoagulated
    - 0 (low risk, 1.9% annual stroke risk): antiplatelet
    - 1 (intermediate risk, 2.8% annual stroke risk): anticoagulant or antiplatelet – patient specific decision
    - >2 (high risk, 4-18.2% annual stroke risk): anticoagulant
  - anticoagulation therapy
    - warfarin (titrate to international normalized ratio 2-3)
    - dabigatran (110 or 150 mg PO bid), apixaban (2.5 or 5 mg PO bid) or rivaroxaban (15 or 20 mg PO daily) may be alternatives to warfarin, but should be used cautiously; Praxbind® reversal agent for dagibatran if necessary

## Hypertension

- primary prevention
  - targets: BP <140/90 (sBP <120 for high risk without diabetes [SPRINT trial] or <130/80 for diabetics or renal disease)
  - ACEI: ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
- secondary prevention
  - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

## Hypercholesterolemia

- primary prevention
  - statins in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
  - high dose atorvastatin (SPARCL trial) but lower doses may be adequate if patient cannot tolerate high dose

## Diabetes

- ideal management: HbA1c <7%, fasting blood glucose 4-7

## Smoking

- primary prevention: smoking increases risk of stroke in a dose-dependent manner
- secondary prevention: after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

## Physical Activity

- beneficial effect of regular physical activity has a dose-related response in terms of intensity and duration of activity

## Stroke Rehabilitation

- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

**$CHADS_2$**
Stroke risk stratification for patients with atrial fibrillation
**C**HF (1 point)
**H**TN sBP >160 mmHg/treated HTN (1 point)
**A**ge >75 yr (1 point)
**D**M (1 point)
Prior **S**troke or TIA (2 points)

Carotid endarterectomy needs to be done within 2 wk of the ischemic event for the most benefit

**$ABCD^2$ Score**
To predict/identify individuals at high risk of stroke following TIA
**A**ge: 1 point for age >60 yr
**B**lood pressure (at presentation):
1 point for HTN
(>140/90 mmHg at initial evaluation)
**C**linical features: 2 points for unilateral weakness, 1 point for speech disturbance without weakness
**D**uration of symptoms: 1 point for 10-59 min, 2 points for >60 min
**D**M: 1 point
Stroke risk: 0-3: low risk, 4-5: moderate risk, 6-7: high risk

**Long-Term Results of Stenting vs. Endarterectomy for Carotid-Artery Stenosis**
NEJM 2016; 374:1021-31
**Study**: Patients were randomly assigned to stenting or endarterectomy and assessed every 6 mo for up to 10 yr.
**Population**: 2502 patients at 117 centres with carotid-artery stenosis.
**Outcome**: Primary composite outcome was stroke, myocardial infarction, or death during periprocedural period or subsequent ipsilateral stroke.
**Results**: There was no significant difference in outcomes of either primary composite endpoint (HR 1.10; 95% CI 0.83-1.44) or post-procedural stroke (HR 0.99; 95% CI 0.64-1.52) in patients treated with stenting or endarterectomy. Asymptomatic and symptomatic patients showed no significant between-group differences in either endpoint.
**Conclusions**: The rate of periprocedural stroke, myocardial infarction, death, and subsequent ipsilateral stroke did not differ between carotid-artery stenosis patients treated with stenting or endarterectomy at 10 yr of follow-up.

**Endovascular Treatment vs. Medical Care Alone for Ischaemic Stroke: Systematic Review and Meta-Analysis**
BMJ 2016;353:i1754
**Purpose**: To evaluate the evidence for endovascular intervention in the treatment of ischemic stroke.
**Study**: Systematic review and meta-analysis of 10 RCTs of 2925 patients testing the efficacy and safety of adjunctive endovascular intervention vs. medical therapy, including thrombolysis, alone in patients suffering acute ischemic stroke in the anterior circulation.
**Results**: The 7 RCTs published or presented in 2015 were without significant heterogeneity and formed the basis for the analysis. The majority of patients (86%) received stent retrievers and experienced higher than expected rates of recanalization (>58%). Risk ratios for good functional outcomes were 1.56 (95%CI 1.38-1.75) and 0.86 for mortality (95% CI 0.69-1.06). There was no difference in symptomatic intracranial hemorrhage following therapy.
**Conclusions**: Endovascular therapy is safe and improves functional outcomes if added to medical care with thrombolysis and administered within 6-8 h of a large-vessel anterior circulation ischemic stroke. A trend towards improved mortality exists with complete follow-up results of several key trials pending.

# Cerebral Hemorrhage

- **definition**: intracranial bleeding into brain tissue
- **etiology**: head trauma, hemorrhagic stroke

### Investigations
- general investigations: see *Assessment and Treatment of Ischemic Stroke*, N50
- further investigations
  - LP (if suspect SAH despite negative CT)
  - may require cerebral angiogram if suspecting aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

### Treatment
- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is safe and appropriate management (target sBP 140-160)
  - ICP lowering medical management (if necessary): see Neurosurgery, NS8
- surgical: see Neurosurgery, NS22

**ACE Inhibitor in Stroke Prevention – HOPE Trial**
NEJM 2000;342:145-53
**Study**: Randomized, blinded, placebo-controlled trial. Mean follow-up 5 yr.
**Patients**: 9297 patients ≥55 yr (mean age 66 yr, 73% men) who had evidence of vascular disease or DM plus one other cardiovascular risk factor and who were not known to have a low ejection fraction or heart failure.
**Intervention**: Ramipril 10 mg daily PO versus matching placebo.
**Main Outcomes**: Stroke, MI, or death from cardiovascular causes.
**Results:**

| Outcome | RRR (95%CI) | NNT (CI) |
|---|---|---|
| Stroke | 32% (16-44) | 67 (43-145) |
| MI, stroke, or CV mortality | 22% (14-30) | 26 (19-43) |
| All-cause mortality | 16% (5-25) | 56 (32-195) |

Treatment with ramipril reduced the risk of stroke (3.4% vs. 4.9%; RR 0.68; p<0.001).
**Conclusions**: In adults at high risk for cardiovascular events, ramipril reduced the risk of stroke, as well as other vascular events and overall mortality. In addition, ACEI reduce risk of stroke beyond their hypertensive effect.

# Neurocutaneous Syndromes

- see Pediatrics, P79

# Multiple Sclerosis

### Definition
- a chronic inflammatory disease of the CNS characterized by relapsing-remitting or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

### Clinical Patterns of MS
- relapsing-remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- benign MS (BMS): retrospective diagnosis made after 15 yr of mild disease, with no evidence of worsening (in functional ability and MRI)
- most RRMS goes on to become SPMS

### MS Variants
- **Devic's = neuromyelitis optica (NMO)**: severe optic neuritis and extensive transverse myelitis extending >3 vertebral segments (antibody positive)
- **clinically isolated syndrome (CIS)**: single MS-like episode, which may progress to MS
- **tumefactive MS**: solitary lesion >2 cm mimicking neoplasms on MRI
- **fulminant MS (Marburg)**: rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- **pediatric MS**: onset of MS before the age of 18
  - epidemiology: rare (1.35-2.5 per 100,000 children)
  - presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome, or symptoms of encephalopathy compared to adults
  - course: 98% have RRMS
  - diagnosis and treatment similar to adult MS
  - differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of white matter lesion, rule out ADEM, optic neuritis, transverse myelitis, neuromyelitis optica, CNS malignancies, leukodystrophies, and mitochondrial disease
- **acute disseminated encephalomyelitis (ADEM)**: monophasic demyelinating disorder with multifocal neurologic symptoms seen mainly in children, often following infection or vaccination

### Etiology
- **genetic**
  - polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- **environmental**
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, SE Australia)
  - MS has also been linked to certain viruses (e.g. EBV)

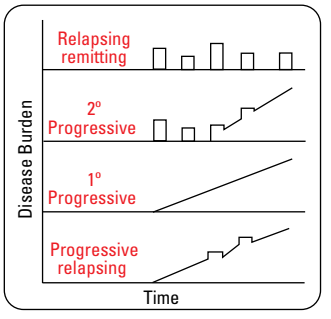

**Figure 27. Clinical patterns of MS**

Most symptoms in MS are due to cord, brainstem, and optic nerve lesions

**Chronic Cerebrospinal Venous Insufficiency (CCSVI)**
A theory proposed in 2008 described abnormal venous blood flow in patients with MS; while some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

**The Expanded Disability Status Scale (EDSS)** is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

## Epidemiology
- onset 17-35 yr; F:M = 3:1
- PPMS occurs in an older population with F=M

## Diagnosis for MS
- demonstration of both dissemination in time and space based on the revised McDonald criteria (2017)
  - dissemination in time: ≥2 attacks, simultaneous presence of gadolinium enhancing and non-enhancing MRI lesions at any time, or a new T2 and/or gadolinium-enhancing lesion(s) on follow-up MRI, presence of CSF oligoclonal bands
  - dissemination in space: ≥1 T2 lesions on MRI in at least 2 of the 4 CNS regions (periventricular, juxtacortical, infratentorial, or spinal cord) or developing a second attack that implicates a different CNS region

## Clinical Features
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- **Lhermitte's sign:** flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- **Uhthoff's phenomenon**: worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically presents as weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4-0.6 relapses per yr, but higher disease activity in first yr of disease

## Investigations
- **MRI**: demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
  - Dawson's fingers: periventricular lesions extending into corpus callosum
  - cranial MRI is more sensitive than spinal MRI
- **CSF**: oligoclonal bands in 90%, increased IgG concentration
- **evoked potentials** (visual/auditory/somatosensory): delayed but well-preserved wave forms

## Treatment
- **acute treatment**: methylprednisolone 1000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids, may consider plasma exchange
- **long-term treatment**: vitamin D 4000 units/d
- **disease modifying therapy (DMT)**
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: teriflunomide, interferon-β (injection: Betaseron®, Avonex®, Rebif®), glatiramer acetate (injection: Copaxone®), BG-12 (Tecfidera®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion), fingolimod (Gilenya®)
  - increased risk of progressive multifocal leukoencephalopathy (PML) associated with natalizumab
  - CIS: early treatment with interferons may delay potential second attack
  - RRMS: DMT reduces rate of relapse by about 30%
  - PPMS: ocrelizumab infusion (ORATORIO trial 2017)
  - SPMS: no proven efficacy of DMTs, some evidence for interferon-β
- **symptomatic treatment**
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantadine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil (Viagra®), tadalafil (Cialis®), vardenafil (Levitra®, Staxyn®)
- **education and counselling**: MS Society, support groups, psychosocial issues

## Prognosis
- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

**Fingolimod for Relapsing-Remitting Multiple Sclerosis**
Cochrane DB Syst Rev 2016;4:CD009371
**Purpose**: Systematic literature review of the evidence for fingolimod in treatment of relapsing-remitting MS.
**Study**: Meta-analysis of six RCTs (N=55,152 patients) investigating the benefits and harms of fingolimod and other disease modifying drugs in the treatment of relapsing-remitting MS.
**Results**: Compared to placebo and interferon beta-1a, fingolimod increases the probability of being relapse free at 24 mo (RR 1.44 vs. placebo, RR 1.18 vs. interferon β-1a) but has little to no effect on disability progression (RR 1.07 vs. placebo, RR 1.02 vs. interferon β-1a). Fingolimod use was associated with a higher incidence of adverse events and discontinuation within 6 mo.
**Conclusions**: Fingolimod significantly reduces disease activity in relapse-remitting MS compared to placebo but does not prevent disability. Its use is associated with adverse events and requires close patient monitoring, particularly within the first 6 mo. Further study is needed to assess the benefits of fingolimod versus other disease modifying drugs.

**Recombinant Interferon β or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis**
Cochrane DB Syst Rev 2008;2:CD005278
**Study**: Meta-analysis of RCTs investigating clinically isolated syndrome (CIS) pateints treated with immunomodulatory drugs.
**Primary Outcomes**: Proportion of patients converting to clinically definite MS and adverse effects.
**Results**: Three trials (n=1160) tested the efficacy of interferon (IFN-α) and no trial tested glatiramer acetate (GA). The pooled odds ratio (OR) for patients on IFN versus placebo at 1 yr was 0.53 (95% CI 0.40-0.71, p<0.0001). The 2 yr follow-up OR was 0.52 (95% CI 0.38-0.70, p<0.0001). There was no significant increase in adverse events for those on IFN-α.
**Conclusions**: IFN-α treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.

# Common Medications

## Table 25. Common Medications – Major Issues

| Indications | Mechanism of Action/Class | Generic Name | Trade Name | Dosing | Contraindications | Side Effects |
|---|---|---|---|---|---|---|
| **Parkinson's Disease** | Dopamine precursor | levodopa + carbidopa | Sinemet® | Carbidopa 25 mg/levodopa 100 mg PO tid<br>Maximum 200 mg carbidopa and 2000 mg levodopa/d | Narrow-angle glaucoma, use of MAO inhibitor in last 14 d, history of melanoma or undiagnosed skin lesions | Nausea, hypotension, hallucinations, dyskinesias |
| | Dopamine agonist | bromocriptine | Parlodel® | 1.25 mg PO bid, increase by 2.5 mg/d q2-4wk, up to 10-30 mg PO tid | Concomitant use of potent inhibitors of CYP3A4, uncontrolled HTN, ischemic heart disease, peripheral vascular disease; caution with renal or hepatic disease | Hypotension, N/V, dizziness, constipation, diarrhea, abdominal cramps, H/A, nasal congestion, drowsiness, hallucinations |
| | MAOB inhibitor | selegiline | Eldepryl® | 5 mg PO bid | Concomitant use of meperidine or tricyclic antidepressants | H/A, insomnia, dizziness, nausea, dry mouth, hallucinations, confusion, orthostatic hypotension, increased akinesia, risk of hypertensive crisis with tyramine-containing foods |
| **Myasthenia Gravis** | Acetylcholinesterase inhibitor | pyridostigmine | Mestinon® | 600 mg/d PO divided in 5-6 doses<br>Range 60-1500 mg/d | GI or GU obstruction | N/V, diarrhea, abdominal cramps, increased peristalsis, increased salivation, increased bronchial secretions, miosis, diaphoresis, muscle cramps, fasciculations, muscle weakness |
| **Acute Migraine** | Triptan (selective 5-hydroxytryptamine receptor agonist) | sumatriptan | Imitrex® | 25-100 mg PO prn, maximum 200 mg/d | Hemiplegic/basilar migraine, ischemic heart disease, CVD, uncontrolled HTN, use of ergotamine/5-HT1 agonist in past 24 h, use of MAO inhibitor in last 14 d, severe hepatic disease | Vertigo, chest pain, flushing, sensation of heat, hypertensive crisis, peripheral vascular disease, coronary artery vasospasm, cardiac arrest, nausea, vomiting, H/A, hyposalivation, fatigue |
| | Ergot (5-HT1D receptor agonist) | dihydroergotamine | Migranal® | Nasal spray 0.5 mg/spray, maximum 4 sprays/d | Hemiplegic/basilar migraine, high-dose ASA therapy, uncontrolled HTN, ischemic heart disease, peripheral vascular disease, severe hepatic or renal dysfunction, use of triptans in last 24 h, use of MAO inhibitors in last 14 d | Coronary artery vasospasm, transient myocardial ischemia, MI, ventricular tachycardia, ventricular fibrillation; may cause significant rebound H/A |
| **Migraine Prophylaxis** | Anticonvulsant | topiramate | Topamax® | 25 mg PO OD (in evening); may increase weekly by 25 mg/d to a max 50 mg bid | | Sedation, mood disturbance, cognitive dysfunction, anorexia, nausea, diarrhea, paresthesias, metabolic acidosis, glaucoma, SJS/TEN |
| | β-blocker | propranolol | Inderal® | 80 mg/d divided every 6-8 h; increase by 20-40 mg/dose every 3-4 wk to max 160-240 mg/d in divided doses q6-8h | Uncompensated CHF, severe bradycardia or heart block, severe COPD or asthma | Fatigue, cognitive dysfunction, disturbed sleep, rashes, dyspepsia, dry eyes, heart failure, bronchospasm, risk of acute tachycardia and HTN if withdrawal |
| **Epilepsy** | Anticonvulsant for partial ± 2º generalization, generalized tonic-clonic | carbamazepine | Tegretol® | Start at 100-200 mg PO OD-tid, increase by 200 mg/d up to 800-1200 mg/d | History of bone marrow depression, hepatic disease, hypersensitivity to the drug, use of MAO inhibitor in last 14 d | Drowsiness, H/A, unsteadiness, dizziness, N/V, skin rash, agranulocytosis/aplastic anemia (rare) |
| | Anticonvulsant for partial, tonic-clonic, status epilepticus | phenytoin | Dilantin® | 100 mg PO tid, maintenance dose up to 200 mg PO tid<br>SE: 10-15 mg/kg IV loading dose then maintenance doses of 100 mg PO or IV q6-8h | Hypersensitivity, pregnancy, breastfeeding; caution with P-450 interactions | Hypotension, SJS/TEN, SLE-type symptoms, gingival hypertrophy, peripheral neuropathy, H/A, blood dyscrasias, nystagmus, N/V, constipation, sedation, teratogenic |
| | Anticonvulsant for partial or generalized, absence seizures | valproic acid | Depakene® Apo-Valproic® | 10-15 mg/kg/d PO in divided doses, increase incrementally until therapeutic dose to max of 60 mg/kg/d | Hypersensitivity, hepatic disease, urea cycle disorders | Hepatic failure, H/A, somnolence, alopecia, N/V, diarrhea, tremor, diplopia, thrombocytopenia, hypothermia, pancreatitis, encephalopathy |
| | Anticonvulsant for absence seizures | ethosuximide | Zarontin® | 500 mg/d PO, increase by 250 mg every 4-7 d to max 1.5 g/d in divided doses | Hypersensitivity (succinimides) | CNS depression, blood dyscrasias, SLE, SJS, GI symptoms |
| **Stroke Prevention in Atrial Fibrillation** | Anticoagulant (direct thrombin inhibitor) | dabigatran | Pradaxa® | 110 mg PO bid or 150 mg PO bid | CrCl <30 mL/min, significant hemostatic impairment, or CNS lesions within 6 mo with high risk of bleeding | Dyspepsia, gastritis, bleeding |
| | Anticoagulant (Factor Xa inhibitor) | rivaroxaban | Xarelto® | 15 mg PO daily or 20 mg PO daily | Concomitant anticoagulant, hepatic disease, pregnancy, strong CYP3A4 and P-gp inhibitors e.g. itraconazole, ritonavir | Bleeding |
| | Anticoagulant (Factor Xa inhibitor) | apixaban | Eliquis® | 2.5 mg PO bid or 5 mg PO bid | Active bleeding, gastrointestinal bleeding, recent cerebral infarction, active peptic ulcer disease with recent bleeding, hepatic disease with coagulopathy | Bleeding (conjunctival, gastrointestinal, gingival, contusion, hematoma, epistaxis, hematuria) |

**Table 25. Common Medications – Major Issues** (continued)

| Indications | Mechanism of Action/Class | Generic Name | Trade Name | Dosing | Contraindications | Side Effects |
|---|---|---|---|---|---|---|
| **Mild to Moderate Alzheimer's Disease or Dementia with Lewy Bodies** | Cholinesterase Inhibitor | donepezil | Aricept® | 5 mg PO OD, may increase to 10 mg PO OD after 4-6 wk | Hypersensitivity to donepezil or to piperidine derivatives | Diarrhea, N/V, insomnia, muscle cramps, fatigue, anorexia, HTN, syncope, AV block |
| **Multiple Sclerosis** | MS Disease Modifying Therapy | interferon-β-1b<br>interferon-β-1a SC<br>interferon-β-1a IM | Betaseron®<br>Rebif®<br>Avonex® | 0.25 mg (8 MU) SC every other day<br>44 µg SC 3 times/wk<br>30 µg IM once weekly | Pregnancy, hypersensitivity to natural or recombinant interferon-β | Injection site reactions, injection site necrosis, flu-like symptoms (fever, chills, myalgia; tend to decrease over time) |
| | MS Disease Modifying Therapy | glatiramer acetate | Copaxone® | 20 mg SC OD | Hypersensitivity to glatiramer or mannitol | Injection site reactions, nausea, transient chest pain, vasodilation |
| | MS Disease Modifying Therapy | natalizumab | Tysabri® | 300 mg IV given over 1 h, every 4 wk | Hypersensitivity to natalizumab, progressive multifocal leukoencephalopathy (PML) | Rash, nausea, arthralgia, H/A, infections, rare risk of PML and melanoma |
| | MS Disease Modifying Therapy | fingolimod | Gilenya® | 0.5 mg PO OD | Not available | Diarrhea, transaminitis, H/A, bradyarrhythmia, lymphopenia |
| **Spasticity (i.e. MS)** | Muscle Relaxant – Antispastic | baclofen | Lioresal® | 5 mg PO tid, increase by 15 mg/d q3d<br>to max dose 80 mg/d in three divided doses | Hypersensitivity to baclofen | Transient drowsiness, daytime sedation, dizziness, weakness, fatigue, convulsions, constipation, nausea |

# Landmark Neurology Trials

| Trial | Reference | Results |
|---|---|---|
| NASCET | *NEJM* 1991;7:445-53 | Patients with symptomatic carotid stenosis of 70-99% benefited more from carotid endarterectomy than best medical therapy |
| Interferon-β Multiple Sclerosis Study Group Trial | *Neurology* 1993;43:655-61 | Interferon-β-1b reduces relapse rate and severity of relapses in RRMS |
| NINDS rtPA | *NEJM* 1995;333:1581-7 | rtPA reduces mortality and long-term disability when administered within 3 h of acute stroke |
| SPARCL | *NEJM* 2006;355:549-59 | The observed benefit of statins in cardiovascular disease is also extended to patients with a recent stroke or TIA |
| ECASS 3 | *NEJM* 2008;359:1317-29 | rtPA improved clinical outcomes when administered within 3 to 4.5 h of acute ischemic stroke |
| PROFESS | *NEJM* 2008;359:1238-51 | ASA + dipyridamole and clopidogrel showed similar benefits in secondary stroke prevention |
| RELY | *NEJM* 2009;361:1139 | Dabigatran superior to warfarin for stroke prevention in patients with AF |
| ROCKET-AF | *NEJM* 2011;365:883-91 | Rivaroxaban noninferior to warfarin for stroke prevention in patients with AF |
| ERS | *NEJM* 2011;365:981-92 | Apixaban superior to warfarin for stroke prevention in patients with AFT |
| CREST | *NEJM* 2010;363:11-23 | Carotid stenting and endarterectomy had similar benefits in reduction of stroke, MI, and death in carotid stenosis, but in the periprocedural period, stenting had a higher rate of stroke, while endarterectomy had a higher rate of MI |
| INTERACT2 | *NEJM* 2013;368:2355-65 | Intensive lowering of blood pressure (sBP<140) in spontaneous intracerebral hemorrhage did not improve mortality or severe disability but improved functional outcomes (odds ratio for greater disability 0.87, 95% CI 0.77-1.00, p=0.04) |
| MR CLEAN | *NEJM* 2015;372:11-20 | Intra-arterial treatment (intra-arterial thrombolysis, mechanical treatment, or both) for emergency revascularization administered within 6 h after stroke onset was effective and safe for acute ischemic stroke caused by proximal intracranial occlusion of the anterior circulation |

14. Posterior spinal
15. Anterior choroidal
16. Medial lenticulostriate
17. Lateral lenticulostriate
18. Penetrating branches of posterior spinal artery (P1 segment)

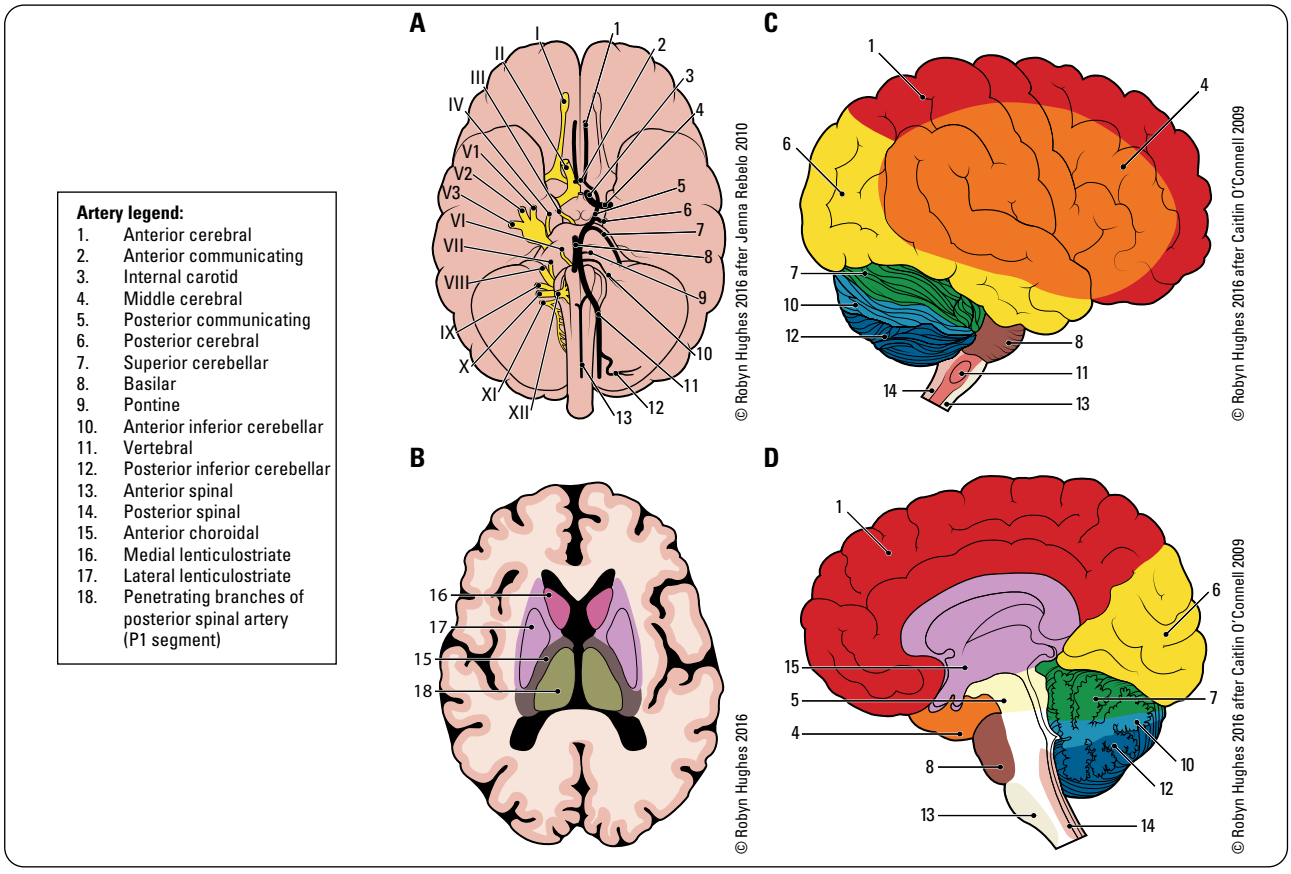

**Figure 4. Vascular supply of the brain**
Please see legend for artery names. 4A. Circle of Willis, most common variant. 4B. Vascular territories of the brain and brainstem, sagittal view, seen laterally. 4C. Vascular territories of the brain and brainstem, sagittal view, seen medially

# Differential Diagnoses of Common Presentations

| Intracranial Mass Lesions | Disorders of the Spine | Peripheral Nerve Lesions |
|---|---|---|
| **Tumour**<br>Metastasis<br>Astrocytoma<br>Meningioma<br>Vestibular schwannoma (acoustic neuroma)<br>Pituitary adenoma<br>Primary CNS lymphoma<br><br>**Pus/Inflammation**<br>Cerebral abscess, extradural abscess, subdural empyema<br>Encephalitis (see Infectious Diseases, ID16)<br>Tumefactive MS<br><br>**Blood**<br>Extradural (epidural) hematoma<br>Subdural hematoma<br>Ischemic stroke<br>Hemorrhage: SAH, ICH, IVH<br><br>**Cyst**<br>Arachnoid cyst<br>Dermoid cyst<br>Epidermoid cyst<br>Colloid cyst (3rd ventricle) | **Extradural**<br>Degenerative: disc herniation, canal stenosis, spondylolisthesis/spondylolysis<br>Infection/inflammation: osteomyelitis, discitis<br>Ligamentous: OPLL<br>Trauma: mechanical compression/instability, hematoma<br>Tumours (55% of all spinal tumours): lymphoma, metastases (lymphoma, lung, breast, prostate), neurofibroma<br><br>**Intradural Extramedullary**<br>Vascular: dural AVF, subdural hematoma (especially if on anticoagulants)<br>Tumours (40% of all spinal tumours): meningioma, schwannoma, neurofibroma<br><br>**Intradural Intramedullary**<br>Tumours (5% of all spinal tumours): astrocytomas, ependymomas, hemangioblastomas, and dermoids<br>Syringomyelia: trauma, congenital, idiopathic<br>Infectious/inflammatory: TB, sarcoid, transverse myelitis<br>Vascular: AVM, ischemia | **Neuropathies**<br>Traumatic<br>Entrapments<br>Iatrogenic<br>Inflammatory<br>Tumours |

# INTRACRANIAL PATHOLOGY

## Intracranial Pressure Dynamics

**Table 1. Approach to Intracranial Pathology**

| Issue | Time Frame | Features |
|---|---|---|
| **Vascular** | Sudden | No H/A = occlusive<br>H/A = hemorrhagic |
| **Metabolic** | Hours to days | Affects entire CNS |
| **Infectious** | Days to weeks | Often a source of infection or immunodeficiency on history |
| **Tumour** | Months | Increased ICP:<br>Initially → H/A<br>Constant<br>Progressive<br>Severe<br>Worse in morning and/or wakes from sleep<br>As ICP increases:<br>Blurry vision<br>Projectile vomiting (may initially present without nausea)<br>Severely raised ICP:<br>Cushing's reflex<br>1. Bradycardia<br>2. HTN<br>3. Respiratory irregularity |

**Table 2. Consequences of Common Brain Lesions**

| Location of Lesion | Consequence |
|---|---|
| **Frontal Lobe**<br>Usually large lesions produce symptoms | Abulia, disinhibition, apathy, executive dysfunction, deficits in orientation and judgment, ± primitive reflex re-emergence, ± contralateral UMN signs (upgoing Babinski reflex and pronator drift) |
| **Frontal Eye Fields** | Gaze deviation toward side of a destructive lesion<br>Gaze deviation away from irritative lesion (i.e. seizure) |
| **Broca's Area**<br>Posterior inferior frontal gyrus of dominant hemisphere | Non-fluent, dysarthric, aphasia<br>Repetition impaired<br>Comprehension spared |
| **Occipital Lobe** | Contralateral homonymous hemianopsia |
| **Parietal Lobe**<br>Either side<br>Dominant side (Left)<br>Non-dominant side (Right) | Dressing apraxia, cortical sensory loss, lower homonymous quadrantanopia<br>Inattention or extinction of non-dominant side<br>Aphasias, Gerstmann's syndrome<br>Hemispatial neglect, apraxias, agnosias (if temporal involvement) |
| **Temporal Lobe** | Hippocampus: anterograde amnesia<br>Upper homonymous hemianopia<br>Wernicke's aphasia (if left/dominant side) |
| **Wernicke's Area**<br>Posterior superior temporal gyrus of dominant hemisphere | Fluent aphasia<br>Repetition impaired<br>Comprehension impaired |
| **Basal Ganglia** | Resting tremor<br>Chorea<br>Athetosis<br>Hemiplegia if internal capsule involved |
| **Subthalamic Nucleus** | Contralateral hemiballismus |
| **Brainstem** | Absent brainstem reflexes: oculocephalic, oculovestibular, corneal, gag, and cough<br>Dorsal midbrain/pineal gland: Parinaud's syndrome (supranuclear upward gaze palsy)<br>Pons: locked-in syndrome<br>Below red nucleus: decerebrate posture<br>Above red nucleus: decorticate posture<br>Reticular activating system (midbrain): reduced level of arousal<br>Cerebellar pontine angle: disequilibrium, ataxia, and other CN V,VII,VIII deficits |
| **Cerebellar Hemisphere** | Intention tremor<br>Ipsilateral limb ataxia<br>Fall towards side of lesion |
| **Cerebellar Vermis** | Truncal ataxia<br>Dysarthria |

# ICP/Volume Relationship

- Monro-Kellie Doctrine: the brain is encased in a rigid skull with constant intracranial volume consisting of CSF, blood, and brain
- the increase in one constituent will: 1) necessitate the redistribution of CSF, blood, and/or brain and 2) increase ICP
- compensatory mechanisms initially maintain a normal ICP
- compensatory reserve (spatial compensation): 60-80 mL in young people, 100-140 mL in elderly (largely due to cerebral atrophy)
  - **immediate**: egression of CSF through foramen magnum to spinal canal, displacement of venous blood from sinuses into jugular veins
- once compensation is exhausted, ICP rises exponentially:
  - **late**: displacement of arterial blood (decreased CPP) eventually leading to ischemia, increasing brain edema, or expanding mass displaces parenchyma into compartments under less pressure (Table 3)
  - **end**: cessation of cerebral perfusion when ICP>MAP, cerebral herniation down into foramen magnum

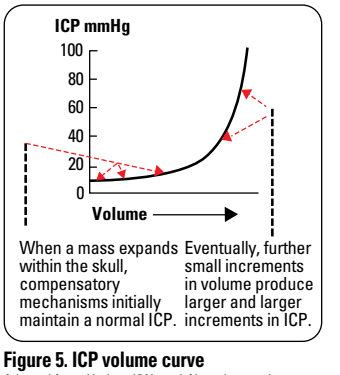

**Figure 5. ICP volume curve**
Adapted from: Lindsay KW, et al. Neurology and neurosurgery illustrated. © 2004. With permission from Elsevier

# Cerebral Blood Flow

- brain receives about 15% of cardiac output (~750 mL/min)
- CBF is the vital parameter for brain function, it depends on CPP and CVR
- CPP is the difference between MAP and ICP (normal CPP >50 mmHg)
- cerebral autoregulation: mechanism that maintains constant CBF despite changes in CPP, unless:
  - high ICP such that CPP <40 mmHg
  - MAP >150 mmHg or MAP <50 mmHg (these setpoints can be higher in hypertensives, thus important to avoid hypotension)
  - increased $CO_2$ = increased CBF via vasodilation
  - $O_2$ <50 mmHg = increased CBF via vasodilation
  - brain injury: e.g. SAH, severe trauma

CBF = CPP / CVR
CPP = MAP – ICP

**MAP Targets in Trauma**
Traumatic brain injury (TBI): MAP >80 mmHg
Spinal cord injury (SCI): MAP between 85-90 mmHg in first 7 d post injury

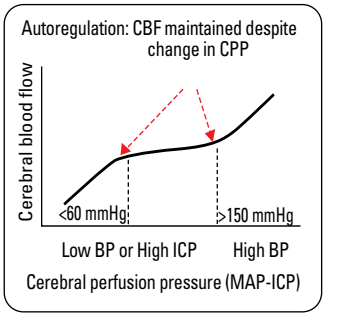

**Figure 6. Cerebral autoregulation curve**
Adapted from: Lindsay KW, et al. Neurology and neurosurgery illustrated. © 2004. With permission from Elsevier

# ICP Measurement

- normal ICP 10-15 mmHg for adult, 3-7 mmHg for child, 1.5-6 mmHg for infant; varies with patient position
- moderate elevation >20 mmHg
- severe elevation >40 mmHg

### Acute Monitoring
- indications include: severe TBI (GCS <8T) + abnormal CT; normal CT if two or more of age >40, blood pressure <90 mmHg, or abnormal motor posturing
- methods: intraventricular catheter (external ventricular drain) is the "gold standard"; most accurate method and allows therapeutic drainage of CSF. Non-invasive methods (including transcranial Doppler, CT/MRI, fundoscopy etc) fail to measure ICP accurately enough to be used as routine measurement techniques

### Chronic Monitoring
- fibre-optic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

# Elevated ICP

### Etiology
- pathologic structure
  - intracranial mass (tumour, cyst)
  - cerebral edema
    - vasogenic: BBB compromised (meningitis, hypertensive encephalopathy, tumour, late ischemia)
    - cytotoxic: BBB intact (cell death in: early ischemia, brain injury, encephalitis, status epilepticus)
    - interstitial: transudation of CSF into peri-ventricular white matter in hydrocephalus
    - osmotic: osmotic gradient increases intracellular free $H_2O$ (acute hyponatremia, hepatic encephalopathy)
  - other space occupying lesions: depressed skull fracture, foreign body, pus/empyema
- increased intracranial blood volume
  - space occupying blood: epidural and subdural hematomas, intraparenchymal and SAHs
  - venous obstruction (venous sinus thrombosis, superior vena cava syndrome, cor pulmonale, venous sinus compression)
  - impaired autoregulation (hypotension, HTN, brain injury, status epilepticus)
  - vasodilatation (increased $pCO_2$/decreased $pO_2$/decreased extracellular pH)
- **increased intracranial CSF volume** (see *Hydrocephalus*, Table 6, NS9)
  - non-obstructive: increased production (rare, choroid plexus papilloma), decreased absorption
  - obstructive: blockage in CSF pathway
- **idiopathic intracranial HTN** (pseudotumour cerebri) – see *Idiopathic Intracranial Hypertension*, NS8

Lumbar puncture can be used for ICP monitoring, though it is not the most accurate. LP can precipitate tonsillar and uncal herniation with elevated ICP and is absolutely contraindicated with known/suspected intracranial mass

**Consider Monitoring ICP in the following Situations**
- Patients with an abnormal head CT (SAH, hematoma, contusion, basal cistern compression, swelling, and herniation), and GCS score ≤8 after CPR

Or
- Patients with a normal head CT and GCS score of ≤8 AND the presence of two or more of the following:
  - >40 yr
  - Unilateral or bilateral motor posturing
  - sBP <90 mmHg
  - Post-operative monitoring
  - Investigation of NPH

**Cautioned Medication Use in Elevated ICP**
- Nitroprusside – can raise ICP in patients with intracranial mass lesions due to direct vasodilation (arterial>venous)
- Nitroglycerine – can raise ICP via vasodilation but less so than nitroprusside because venous>arterial
- Succinylcholine – induced fasciculations may increase ICP

## Clinical Features

### Table 3. Clinical Features of Elevated ICP

| Clinical Features | Acutely Elevated ICP | Chronic Progressive ICP Elevation |
|---|---|---|
| **Headache** | Both aggravated by stooping, coughing, and straining<br>Morning H/A: vasodilatation due to increased $CO_2$ with recumbency | |
| **Nausea and Vomiting** | Present in both, though greater predilection in acutely elevated ICP | |
| **Level of Consciousness** | Lethargy if ICP = dBP or midbrain compression | Irritability, inattentiveness. Normal or modestly reduced LOC, confusion |
| **GCS** | Significant decline in GCS<br>Best index to monitor progress and predict outcome of acute intracranial process (see *Neurotrauma*, NS30) | Can be unchanged or modestly decreased |
| **Optic Disc Changes** | Subtle changes suggesting papilledema (subtle elevations in disc margin, mild disc hyperemia) ± retinal hemorrhages (may take 24-48 h to develop) | Obvious papilledema |
| **Visual Changes** | Less common. Often not affected initially, however visual obscurations, flickering, or blurring can occur | Optic atrophy/blindness due to chronic papilledema<br>Enlarged blind spot, if advanced → episodic constrictions of visual fields ("grey-outs" lasting ~20 min)<br>Differentiate from papillitis (usually unilateral with decreased visual acuity) |
| **Extra-Ocular Movements** | Less common. CN VI palsy: due to long intracranial course, more sensitive to ICP changes and thus earlier sign of acutely increased ICP<br>Often falsely localizing (causative lesion remote to nerve)<br>**Upward gaze palsy and sunset eyes** (especially in children with obstructive hydrocephalus) | Often full extraocular movement |
| **Herniation Syndromes** | Often occur | Present if acute on chronic presentation |
| **Neurologic Deficits** | Focal deficits present | Focal deficits can be present |

**Blood Brain Barrier**
Glucose and amino acids cross slowly
Non-polar/lipids cross fast

Infarction/neoplasm → destroy tight junctions → vasogenic edema

**Cushing's Triad of Acute Raised ICP**
(full triad seen in 1/3 of cases)
- Hypertension
- Bradycardia (late finding)
- Irregular respiratory pattern

**Papilledema**
- Optic disc swelling with blurred margins (most commonly bilateral)
- Larger blind spot

### Investigations
- patients with suspected elevated ICP require an urgent CT/MRI to identify etiology, assess for midline shift/herniation
- ICP monitoring where appropriate

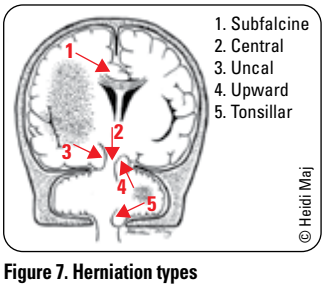

**Figure 7. Herniation types**

# Herniation Syndromes

### Table 4. Herniation Syndromes

| Herniation Syndrome | Definition | Etiology | Clinical Features |
|---|---|---|---|
| **1. Subfalcine** | Cingulate gyrus herniates under falx | Lateral supratentorial lesion | Usually asymptomatic<br>Warns of impending transtentorial herniation<br>Risk of ACA compression |
| **2. Central Tentorial (Axial)** | Displacement of diencephalon through tentorial notch | Supratentorial midline lesion<br>Diffuse cerebral swelling<br>Late uncal herniation | Small pupils, moderately dilated, fixed (rostral to caudal deterioration), sequential failure of diencephalon, medulla<br>Decreased LOC (midbrain compression), EOM/upward gaze impairment ("sunset eyes"): compression of pretectum and superior colliculi (Parinaud's syndrome)<br>Risk of PCA compression<br>Brainstem (Duret) hemorrhage: secondary to shearing of basilar artery perforating vessels<br>Diabetes insipidus (traction on pituitary stalk and hypothalamus), end-stage sign |
| **3. Lateral Tentoria (Uncal)** | Uncus of temporal lobe herniates down through tentorial notch | Lateral supratentorial lesion (often rapidly expanding traumatic hematoma) | Ipsilateral non-reactive dilated pupil (earliest, most reliable sign) + ipsilateral EOM paralysis, ptosis (CN III compression)<br>Decreased LOC (midbrain compression)<br>Risk of PCA compression<br>Contralateral hemiplegia ± extensor (upgoing) plantar response<br>± ipsilateral hemiplegia ("Kernohan's notch" – a false localizing sign resulting from pressure from the edge of the tentorium on the contralateral cerebral peduncle) |
| **4. Upward** | Cerebellar vermis herniates through tentorial incisura | Posterior fossa mass, brainstem or cerebellar infarction, exacerbated by ventriculostomy or VP shunt | Cerebellar infarct (superior cerebellar artery [SCA] compression)<br>Hydrocephalus (cerebral/sylvian aqueduct compression) |
| **5. Tonsillar** | Cerebellar tonsils herniate through foramen magnum | Infratentorial lesion<br>Following central tentorial herniation<br>Following LP in presence of intracranial mass lesion | Neck stiffness and head tilt (tonsillar impaction)<br>Decreased LOC (midbrain compression)<br>Flaccid paralysis<br>Respiratory irregularities, respiratory arrest (compression of medullary respiratory centres)<br>Blood pressure instability (compression of medullary cardiovascular centres) |

# Treatment of Elevated ICP

- treatment principle: treat primary etiology (i.e. remove mass lesions, ensure adequate ventilation for example in ARDS)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- targets: ICP <22 mmHg, CPP 60-70 mmHg, sBP >100 (age 50-69) or >110 (age <50 or >70) mmHg (individualize targets based on patient's clinical picture and progression)

**Table 5. Management of Elevated ICP**

| Consideration | Intervention | Rationale |
|---|---|---|
| **Conservative Measures** | | |
| **Position** | Elevate head of bed at 30°<br>Maintain neck in neutral position | Increases<br>1. Jugular venous patency<br>2. intracranial venous outflow with minimal effect on MAP |
| **Fever Management** | Acetaminophen or mechanical cooling | Decrease metabolic demands to decrease CBF and minimize brain injury |
| **Prevent Hypotension** | PRN: fluid, vasopressors, dopamine, norepinephrine | Maintains CBF |
| **Normocarbia** | Ventilate to $pCO_2$ 35-40 mmHg | Prevents vasodilatation |
| **Adequate $O_2$** | Target $pO_2$ >60 mmHg | Prevents hypoxic brain injury |
| **Osmolar Diuresis** | Mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6h to serum osmolarity of 315-320<br>Acts in 15-30 min, maintain sBP >100 mmHg<br>3% hypertonic saline comparable to mannitol | Increase serum tonicity → osmotically drives fluid out of brain |
| **Corticosteroids** | Dexamethasone | Decrease vasogenic edema over subsequent days around brain tumour, abscess, blood<br>No proven value in head injury or stroke |
| **Aggressive Measures** | | |
| **Sedation** | Usually Propofol<br>Others: barbituates/codeine, or fentanyl/$MgSO_4$<br>Light = barbituates/codeine<br>Heavy = fentanyl/$MgSO_4$ | Reduces sympathetic tone<br>Reduces HTN induced by muscle contraction |
| **Paralysis** | Vecuronium | Reduces sympathetic tone<br>Reduces HTN induced by muscle contraction |
| **Barbiturate-Induced Coma (refractory ICP)** | Phentobarbital 10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion | Reduce CBF and metabolism<br>Decreases mortality, but no affect on neurologic outcome<br>No role for the use of hypothermia in head injury |
| **Hyperventilate** | Target $pCO_2$ 30-35 mmHg<br>Avoid within 24 h following trauma | Decreases CBF and thus ICP but use for brief periods only |
| **Drain CSF** | Insert EVD (if acute) or shunt<br>Drain 3-5 mL CSF | Reduces intracranial volume |
| **Decompression** | Decompressive craniectomy | Allows brain to swell while reducing risk of herniation |

**Treatment of Elevated ICP**

**ICP HEAD**
**I**ntubate
**C**alm (sedate)/**C**oma
**P**lace drain/**P**aralysis
**H**yperventilate
**E**levate head
**A**dequate BP
**D**iuretic (mannitol)

**Trial of Decompressive Craniectomy for Traumatic Intracranial Hypertension**
N Engl J Med 2016;375:1119-30
**Methods**: RCT comparing decompressive craniectomy to barbiturate coma and medical management in 400 patients with TBI and refractory intracranial hypertension. Primary outcome was Extended Glasgow Outcome Scale at 6 mo.
**Results**: Patients treated with decompressive craniectomy had lower mortality rates (26.9% vs. 48.9%) but higher rates of disability (8.5% v. 2.1% lower severe disability, 21.9% v. 14.4% upper severe disability, 15.4% v. 8.0% moderate disability).
**Conclusion**: Compared to medical care, decompressive craniectomy in patients with TBI and refractory intracranial hypertension results in lower mortality and higher rates of vegetative state and severe disability.

# Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)

## Definition
- raised ICP with papilledema, but without: mass, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)
- diagnosed by modified Dandy's criteria

## Etiology
- unknown (majority), but associated with:
  - dural sinus thrombosis
  - **habitus/diet**: obesity, hypervitaminosis A
  - **endocrine**: reproductive age, menstrual irregularities, Addison's/Cushing's disease
  - **hematologic**: iron deficiency anemia, polycythemia vera
  - **drugs**: steroid withdrawal, tetracycline, amiodarone, lithium, nalidixic acid, oral contraceptive, growth hormone, retinoids
- risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones ("fat, female, fertile, forties")

## Epidemiology
- incidence: general population ~1-2/100,000/yr; obese women of childbearing age 19-21/100,000

## Clinical Features
- **symptoms**: H/A in >90%, nausea, transient visual obscurations, pulsatile tinnitus, diplopia can occur with CN VI palsy, neck/back pain
- **signs**: CN VI palsy can occur (otherwise no neurologic deficits), visual acuity and field deficits, papilledema, optic atrophy
- **morbidity**: risk of blindness and severe visual impairment are the major morbidity of IHH (6-24%

**Modified Dandy's Criteria**
1. Symptoms of raised ICP
2. No localizing signs except sixth nerve palsy
3. Patient awake and alert
4. Normal neuroimaging without evidence of thrombosis
5. LP opening pressure >25 cm $H_2O$, normal CSF
6. No better explanation for raised ICP

risk), but are not reliably correlated to duration, symptoms or clinical course
- **clinical course**: usually self-limited, recurrence in 10%, chronic in some

### Investigations
- **MRI-brain** (with and without contrast): slit like ventricles and distended perioptic subarachnoid space, but otherwise normal
  - rule out: venous sinus thrombosis, mass, infection, hydrocephalus
- **LP findings**
  - opening pressure >25 cm $H_2O$
  - normal CSF analysis
- **ophthalmologic**: fields, acuity, papilledema

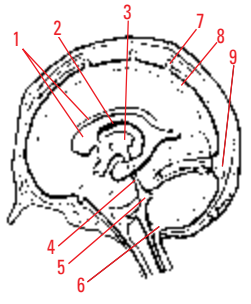
### Treatment
- **lifestyle change**: encourage weight loss, fluid/salt restriction
- **pharmacotherapy**: acetazolamide (decreases CSF production), thiazide diuretic, or furosemide; discontinue offending medications
- **surgery**: if above fail, serial LPs (temporizing), shunts, optic nerve sheath fenestration (if progressive impairment of visual acuity)
- **long term**: 2 yr follow-up, repeat imaging to rule out occult tumour, ophthalmology follow-up

**Effect of Acetazolamide on Visual Function in Patients with Idiopathic Intracranial Hypertension and Mild Visual Loss (IIHTT)**
JAMA 2014;311(16):1641-1651
**Methods**: RCT comparing low-sodium weight-reduction diet plus maximally tolerated dose of acetazolamide (up to 4 g/d) to diet alone in 165 patients with IIH and mild visual loss.
**Results**: Acetazolamide was superior to placebo with regards to perimetric mean deviation improvement (p=0.05), papilledema grade improvement (p<0.001), vision-related quality of life (p=0.003), and weight reduction (p<0.001).
**Conclusion**: Acetazolamide with low-sodium weight-reduction diet resulted in improvement in visual field function in patients with IIH and mild visual loss.

# Hydrocephalus

- for hydrocephalus in children, see *Pediatric Neurosurgery*, NS36

### Definition
- accumulation of excess CSF in the brain, functionally divided into obstructive and communicating
  - flow of CSF: produced by choroid plexus, lateral ventricles → foramen of Monroe → 3rd ventricle → cerebral/Sylvian aqueduct → 4th ventricle → foramina of Luschka (lateral) and Magendie (medial) → subarachnoid space where CSF is re-absorbed by arachnoid villi/granulations into dural venous sinuses



CSF production = CSF reabsorption = ~ 500 mL/d in normal adults
Normal CSF volume ~150 mL (50% spinal, 50% intracranial → 25 mL intraventricular, 50 mL subarachnoid)

### Classification

**Table 6. Classification of Hydrocephalus**

| Disorder | Definition | Etiology | Findings on CT/MRI |
|---|---|---|---|
| **Obstructive (Non-Communicating) Hydrocephalus** | CSF circulation blocked within ventricular system proximal to the arachnoid granulations | **Acquired**<br>**Aqueductal stenosis:** adhesions after infection, hemorrhage; gliosis, tumour (e.g. medulloblastoma)<br>**Intraventricular lesions**: tumours, e.g. 3rd ventricle colloid cyst, hematoma<br>Mass causing tentorial herniation causing aqueduct/4th ventricle compression<br>**Others:** neurosarcoidosis, abscess/granulomas, arachnoid cysts<br><br>**Congenital**<br>Primary aqueductal stenosis, Dandy-Walker malformation, Arnold-Chiari malformation, myelomeningocele, encephalocele (see *Pediatric Neurosurgery*, NS35) | Ventricular enlargement proximal to block (enlarged temporal horns, ballooning frontal and/or occipital horns, enlarged 3rd ± 4th ventricles)<br>Periventricular hypodensity/lucency (transependymal migration of CSF forced into extracellular space)<br>Sulcal effacement, reduced visibility of Sylvian and interhemispheric fissures |
| **Non-Obstructive (Communicating) Hydrocephalus** | Most commonly CSF absorption blocked at extraventricular site = arachnoid granulations, rarely CSF absorption is overwhelmed by increased production | Post-infectious (#1 cause) → meningitis, abscess, cysticercosis<br>Post-hemorrhagic (#2 cause) → SAH, IVH, traumatic<br>Leptomeningeal carcinomatosis – metastatic meningitis<br>Choroid plexus papilloma<br>Idiopathic → NPH | All ventricles dilated |
| **Normal Pressure Hydrocephalus (NPH)** | Persistent ventricular dilatation in the context of normal CSF pressure | Idiopathic (50%)<br>Others: SAH, meningitis, trauma, radiation-induced | Enlarged ventricles without increased prominence of cerebral sulci |
| **Hydrocephalus *Ex Vacuo*** | Ventricular enlargement resulting from atrophy of surrounding brain tissue | Normal aging<br>Degenerative dementias see Neurology, N22 (Alzheimer's, frontotemporal, Creutzfeldt-Jacob disease) | Enlarged ventricles and sulci<br>Cerebral atrophy |

### Etiology
- impaired CSF dynamics
  - obstruction of CSF flow
  - decreased CSF absorption
  - increased CSF production (rarely in choroid plexus papilloma – 0.4-1% of intracranial tumours)
- congenital and acquired causes

1. Lateral ventricles
2. Choroid plexus
3. Third ventricle
4. Cerebral aqueduct (of Sylvius)
5. Fourth ventricle
6. Foramina of Luschka and Magendie
7. Arachnoid granulations
8. Subarachnoid space
9. Superior sagittal sinus

© Kari Francis 2004

**Figure 8. The flow of CFS**

## Epidemiology
- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1000 live births

## Clinical Features
- acute hydrocephalus: signs and symptoms of acutely elevated ICP (see Table 3)
- chronic/gradual onset hydrocephalus: (wk to mo; i.e. NPH) presents with a classic triad (Hakim's Triad)
  - **A**taxia (magnetic gait) + apraxia (pressure of ventricle on lower extremity motor fibres → gait disturbance)
  - **I**ncontinence (pressure on cortical bowel/bladder centre)
  - **D**ementia (subcortical)

**Classic (Hakim's) Triad of NPH Progression**
"Wet, wacky, wobbly": Incontinence, dementia, ataxia

## Investigations
- imaging
  - CT/MRI findings (see Table 6)
  - ultrasound (through anterior fontanelle in infants): ventriculomegaly, size and location of lesions (e.g. IVH)
  - mantle radionuclide cisternography can test CSF flow and absorption rate (unreliable)
- ICP monitoring (e.g. LP, EVD) may be used to investigate NPH and test response to shunting (lumbar tap test)

**Important Features to Note on CT and MRI (± contrast enhancement)**
- Lesions (± edema, necrosis, hemorrhage)
- Midline shifts and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)

## Treatment
- EVD
- intermittent LPs for transient communicating hydrocephalus (SAH, IVH in premature infants)
- eliminating obstruction (i.e. excision of mass, posterior fossa decompression for Chiari Malformation)
- endoscopic
  - endoscopic third ventriculostomy (ETV) ± choroid plexus cauterization (for obstructive hydrocephalus)
  - endoscopic placement of aqueductal stent
- shunt
  - ventriculoperitoneal (VP): most common shunt
  - ventriculopleural (VPl)
  - ventriculoatrial (VA)
  - lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri

## Shunt Complications

**Table 7. Shunt Complications**

| Complication | Etiology | Clinical Features | Investigations |
|---|---|---|---|
| **Obstruction** (most common) Proximal Catheter Valve Distal Catheter | Obstruction by choroid plexus Buildup of proteinaceous accretions, blood, cells (inflammatory or tumour) Infection Disconnection or damage | Acute hydrocephalus signs and symptoms of increased ICP | "Shunt series" (plain x-rays of entire shunt that only rule-out disconnection, break, tip migration) CT Radionuclide "shuntogram" |
| **Infection** (3-6%) | *S. epidermidis* *S. aureus* *P. acnes* Gram-negative bacilli | Fever, N/V, anorexia, irritability Meningitis Peritonitis Signs and symptoms of shunt obstruction Shunt nephritis (VA shunt) | CBC Blood culture Tap shunt for CandS (LP usually NOT recommended) |
| **Overshunting** (10% over 6.5 yr) | Slit ventricle syndrome, collapse of ventricles leading to occlusion of shunt ports by ependymal lining | Chronic or recurring H/A often relieved when lying down | CT/MRI Slit-like ventricles on imaging |
| | Subdural hematoma Collapsing brain tears bridging veins (especially common in NPH patients) | Asymptomatic H/A, vomiting, somnolence | CT |
| | Secondary craniosynostosis (children): apposition and overlapping of the cranial sutures in an infant following decompression of hydrocephalus | Abnormal head shape | Clinical CT |
| **Seizures** (5.5% risk in 1st yr, 1.1% after 3rd yr) | Ventricular shunts only | | EEG |
| **Inguinal Hernia** (17% incidence with VP shunt inserted in infancy) ± skin breakdown over hardware | Increased intraperitoneal pressure/fluid results in hernia becoming apparent | Inguinal swelling, discomfort | U/S |

**Complications of Specific Hydrocephalus Treatments**
1. VP Shunt – intra-abdominal cysts, adhesions, ascites
2. VA Shunt – greater infection risk, septicemia, emboli
3. VPl Shunt – pleural effusion, hydrothorax, respiratory distress
4. LP Shunt – radiculopathy, CSF leaks, adhesions, arachnoiditis
5. ETV – 56% success rate, hypothalamic injury, traumatic basilar aneurysm

# CNS Tumours

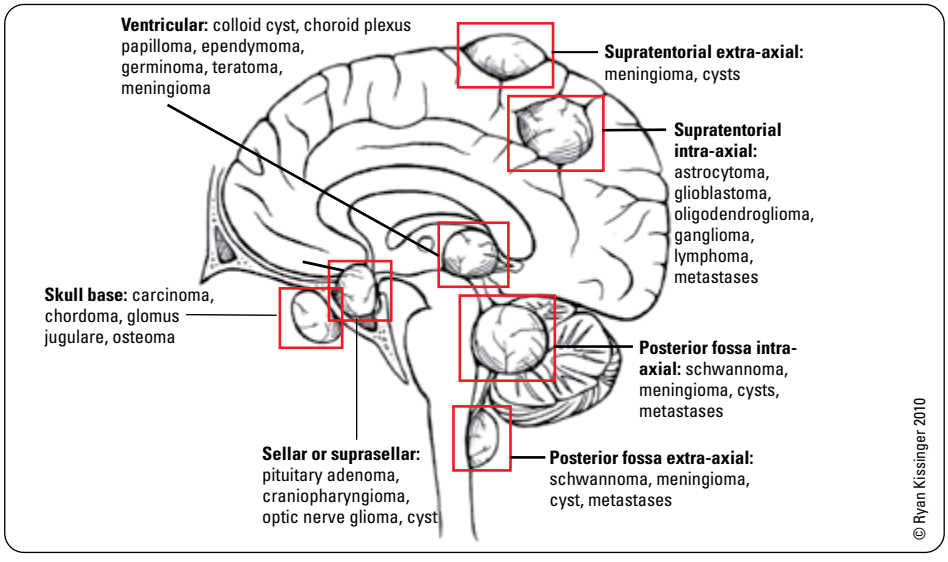


**Figure 9. Tumours of the CNS**

## Classification

- primary vs. metastatic (e.g. primary in breast, lung), intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, but can be devastating due to mass effect in fixed volume of skull (e.g. most meningiomas, WHO Grade I)
- malignant: implies rapid growth, invasiveness, possibly drop-metastases to spinal cord from a primary CNS tumour (rare)
- classification of nervous system tumours (* = most common). In 2007, the WHO Classification of CNS tumours was based solely on histology; an update was made in 2016 which bases the classification on a combination of histology (phenotype) and molecular genetics (genotype) for "integrated" diagnoses:
  - **neuroepithelial**
    - astrocytic tumours
      - oligoastrocytic tumours: oligoastrocytoma
      - neuronal and mixed neuronal-glial tumours: ganglion cell tumours, cerebral neurocytomas
      - embryonal tumours: medulloblastoma, PNET
      - other: pineal, ependymal, and choroid plexus tumours
  - **meningeal**: meningiomas*, mesenchymal, hemangioblastomas
  - **cranial and paraspinal nerves**: schwannoma, neurofibroma
  - **lymphomas and hematopoietic**: primary CNS lymphoma, plasmacytoma
  - **germ cell**: germinomas, teratomas, choriocarcinomas
  - **sellar region**: craniopharyngiomas, spindle cell oncocytoma, pituitary adenomas*
  - **cysts**: epidermoid/dermoid cysts, colloid cysts
  - **local extension**: chordomas, glomus jugulare tumours
  - **metastatic tumours**: lung*, breast*, melanoma

## Familial Syndromes Associated with CNS Tumours

- ataxia telangiectasia, Cowden syndrome, familial adenomatous polyposis, hereditary non-polyposis-related colorectal cancer, Li-Fraumeni Syndrome, Gorlin syndrome, neurofibromatosis Types 1 & 2, multiple endocrine neoplasia type 1, tuberous sclerosis complex, von Hippel-Lindau disease, and Turcot syndrome

## Investigations

- CT, MRI with contrast, stereotactic biopsy (tissue diagnosis and molecular markers for prognosis), metastatic workup, tumour markers (i.e. germ cell tumours)

## Treatment

- **conservative**: serial Hx, Px, imaging for slow growing/benign lesions
- **medical**: corticosteroids to reduce ICP, cytotoxic cerebral edema, pharmacologic (i.e. pituitary adenoma)
- **surgical**: total or partial excision (decompressive, palliative), shunt if hydrocephalus
- **radiotherapy**: conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (SRS) (e.g. Gamma Knife®)
- **chemotherapy**: e.g. alkylating agents (i.e. temozolomide (GBM)*, vincristine, cyclophosphamide, etc.)

**DDx for Ring Enhancing Lesion on CT with Contrast**

**MAGICAL DR**
**M**etastases*
**A**bscess*
**G**lioblastoma (high grade astrocytoma)*
**I**nfarct
**C**ontusion
**A**IDS (toxoplasmosis)
**L**ymphoma
**D**emyelination
**R**esolving hematoma, **R**adiation Necrosis
(*3 most common diagnoses)

**Ring Enhancing Lesions in Patients with HIV**
DDx: Toxoplasmosis or CNS Lymphoma
Tx: Pyrimethamine and Sulfadiazine; later brain biopsy if no resolution with antimicrobial
Primary CNS lymphoma reported in 6-20% of HIV infected patients

**Primary Brain Tumours**
Rarely undergo metastasis
Adults = mostly supratentorial
Children = mostly infratentorial

New onset communicating hydrocephalus in a patient with cancer should raise the suspicion of leptomeningeal carcinomatosis

**Table 8. Tumour Location: Etiology and Clinical Feature**

| | Supratentorial | Infratentorial (Posterior Fossa) |
|---|---|---|
| **Epidemiology** | | |
| **Age <15 yr** Incidence: 2-5/100,000/yr<br>60% infratentorial | Astrocytoma (all grades) (50%)<br>Craniopharyngioma (2-5%)<br>Others: pineal region tumours, choroid plexus tumours, ganglioglioma, DNET | Medulloblastoma (15-20%)<br>Cerebellar astrocytoma (15%)<br>Ependymoma (9%)<br>Brainstem astrocytoma |
| **Age >15 yr**<br>80% supratentorial | High grade astrocytoma (12-15%, e.g. GBM)<br>Metastasis (15-30%, includes infratentorial)<br>Meningioma (15-20%)<br>Low grade astrocytoma (8%)<br>Pituitary adenoma (5-8%)<br>Oligodendroglioma (5%)<br>Other: colloid cyst, CNS lymphoma, dermoid/epidermoid cysts | Metastasis<br>Acoustic neuroma (schwannoma) (5-10%)<br>Hemangioblastoma (2%)<br>Meningioma |
| **Clinical Feature** | | |
| **Shared Features** (from elevated ICP) | **H/A**: usually worse in AM and made worse with straining, coughing<br>**N/V**<br>**Papilledema**<br>**Diplopia** - CN VI palsy | |
| **Distinguishing Features** | **Seizure**: commonly the first symptom<br>Progressive neurological deficits (70%)<br>Frontal lobe: hemiparesis, dysphasia, personality changes, cognitive changes<br>Temporal lobe: auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopsia<br>**Mental Status Change**: depression, apathy, confusion, lethargy<br>**"Tumour TIA"** (transient ischemic attack) stroke like symptoms caused by<br>a) occlusion of vessel by tumour cells<br>b) hemorrhage<br>c) 2° to "steal phenomenon" - blood is shunted from ischemic regions to non-ischemic regions<br>Endocrine disturbance - with pituitary tumours (see Endocrinology, E20) | **Brainstem involvement**: cranial nerve deficits and long tract signs<br>**N/V**: compression on vagal nucleus/area postrema<br>**Diplopia**: direct compression CN VI<br>**Vertigo**<br>**Nystagmus**<br>**Truncal ataxia + titubation**: cerebellar vermis lesions<br>**Limb ataxia, dysmetria, intention tremor:** cerebellar hemisphere lesions<br>**Obstructive hydrocephalus** more common than supratentorial lesions |

# Metastatic Tumours

## Brain Metastasis

- most common intra-cranial tumour in adults (~50% of all brain tumours)
- afflict ~25% of patients with any cancer
- hematogenous spread most common
- 80% are hemispheric, often at grey-white matter junction or temporal-parietal-occipital lobe junction
  - likely emboli spreading to terminal MCA branches

## Investigations

- identify primary tumour
  - full metastatic workup (CXR, CT chest/abdo, abdominal U/S, nuclear medicine scan/PET, mammogram)
- CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
- contrast-enhanced MRI more sensitive, especially for posterior fossa
- consider biopsy in unusual cases or if no primary tumour identified

## Treatment

- medical
  - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  - dexamethasone to reduce edema given with ranitidine
  - chemotherapy (e.g. small cell lung cancer), but difficult delivery across BBB
- radiation
  - SRS (highly focused fraction of radiation targeted to tumour): for discrete, deep-seated/inoperable tumours
  - multiple lesions: use WBRT (upwards of 10 lesions); consider SRS if <3 lesions
  - post-operative adjuvant RT consideration
  - emerging evidence supports avoidance of whole brain radiation and use of focal radiation to spare cognitive functions (refer to Brown et al., 2016)
- surgical
  - single/solitary lesions: surgical resection and radiation in carefully selected patients

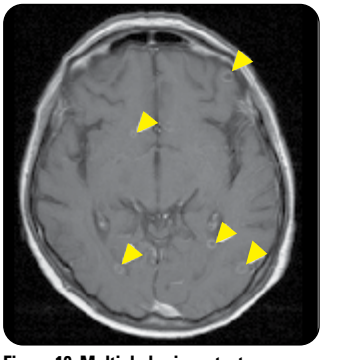

**Figure 10. Multiple brain metastases** (see arrows)

**Most Common Cancers that Metastasize to the CNS**

| Site of Primary | Frequency of CNS metastasize |
|---|---|
| **Lung** | 44% |
| **Breast** | 10% |
| **Kidney (RCC)*** | 7% |
| **GI** | 6% |
| **Melanoma** | 3% |

*RCC=renal cell carcinoma

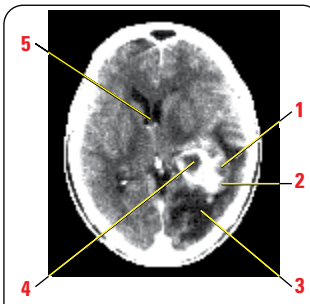
### Prognosis
- median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo. The disease-specific Graded Prognostic Assessment (Ds-GPA) is a useful prognostic index. Prognosis varies depending on primary tumour type and extent of systemic tumour burden

## Astrocytoma
- most common primary intra-axial brain tumour, common in 4th-6th decades

**Table 9. World Health Organization Astrocytoma Grading System**

| | Typical CT/MRI Findings | Survival |
|---|---|---|
| **I – Pilocytic astrocytoma** | ± mass effect, ± enhancement | >10 yr, cure if gross total resection |
| **II – Low grade/diffuse*** | Mass effect, no enhancement | 5 yr |
| **III – Anaplastic*** | Complex enhancement | 1.5-2 yr |
| **IV – Glioblastoma multiforme (GBM)** | Necrosis (ring enhancement) | 12 mo, 10% at 2 yr |

*IDH mutant WHO Gr II/III tumours have a better overall prognosis than IDH wild-type; following IDH stratification, the chromosomal 1p/19q codeletion has prognostic value in IDH mutated grade II–III gliomas after adjustment for tumour proliferation, age, and adjuvant treatment



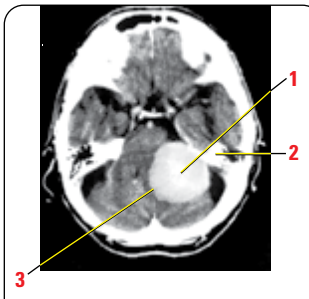
### Clinical Features
- sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
- symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

### Investigations
- CT/MRI with contrast: variable appearance depending on grade
  - hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
  - low grade: most do not enhance and have calcification on CT
  - high grade: most enhance with CT contrast dye/gadolinium, possibly with central necrosis (especially if IDH wildtype)
  - histology during surgical resection or biopsy

### Treatment
- **low grade diffuse astrocytoma**
  - close follow-up, radiation, chemotherapy, and surgery all valid options
  - de-differentiation to more malignant grade; typically occurs faster when diagnosed after age 45
  - surgery: maximal safe resection, not curative, trend towards better outcomes, provides tissue sample for histologic/molecular characterization
  - radiotherapy alone or post-operative prolongs survival (retrospective evidence)
  - chemotherapy: usually reserved for tumour progression
- **high grade astrocytomas** (anaplastic astrocytoma and GBM)
  - goal is to prolong "quality" survival
  - **surgery**
    - gross total resection: maximal safe resection + fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
      - except: nearing end-of-life; or extensive brainstem, bilateral, or dominant lobe GBM involvement
    - awake craniotomy for tumours in 'eloquent' regions (e.g. speech and language regions or near motor strip)
    - stereotactic biopsy if resection not possible, followed by fractioned radiation with 2 cm margin
  - **expectant** (based on functional impairment – Karnofsky score <70; patient's/family's wishes)
  - **chemotherapy**: ~20% response rate, temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene hypermethylation
- **multiple gliomas**: WBRT ± chemotherapy

## Meningioma
- most common ***primary*** intracranial tumour, arising from arachnoid membrane
- often calcified, may cause hyperostosis of adjacent bone (detectable on imaging)
- classically see Psammoma bodies ("meningocytic whorls") on histology
- location: 70% occur along the parasagittal convexity, falx cerebri, and sphenoid bone; other locations: tuberculum sellae, foramen magnum, olfactory groove, and CP angle

### Clinical Features
- middle aged, slight female predominance (M:F = 1:1.8), high progesterone receptors (increase in size with pregnancy)
- many are asymptomatic and can be an incidental finding; when symptoms occur focal neurologic deficits specific to location, ± seizures, symptoms of increased ICP
- molecular changes: between 40-80% of meningiomas contain mutations in chromosome 22 (involved in suppressing tumour growth); some have extra copies of PDGFR and EGFR; some are associated with mutations in the NF2 gene



1. Heterogenous contrast enhancement
2. Ill-defined borders (infiltrative)
3. Peritumoural edema
4. Central necrosis
5. Compression of ventricles, midline shift

**Figure 11. High grade astrocytoma on CT**

**Comparison of a Strategy Favouring Early Surgical Resection vs. a Strategy Favouring Watchful Waiting in Low-Grade Gliomas**
JAMA 2012; 308(18): 1881-8
**Purpose**: To examine "watchful waiting" vs. early surgical resection of low grade gliomas.
**Study**: A population-based parallel cohort study was undertaken between two hospitals that each favoured different management approaches for low grade gliomas (biopsy and watchful waiting vs. early surgical resection).
**Results**: 66 patients were included from the watchful waiting hospital and 87 patients from the early resection centre. Median follow-up was 7.0 and 7.1 years at each centre. The two groups were equivalent in terms of baseline parameters. Overall, survival was significantly better with early surgical resection (watchful waiting: median survival of 5.9 years 95% CI, 4.5-7.3 vs. early resection: median survival was not reached due to prolonged length of life, p<0.01).
**Conclusions**: Early surgical resection of low grade-gliomas is associated with better overall survival as compared to watchful waiting.

**Bevacizumab Plus Radiotherapy-Temozolamide for Newly Diagnosed Glioblastoma**
NEJM 2014;370:709-722
**Purpose**: To evaluate the effect of combined bevacizumab and radiotherapy-temozolamide in the treatment of newly diagnosed glioblastoma.
**Study**: Patients with supratentorial glioblastoma randomly assigned to receive intravenous bevacizumab or placebo plus radiotherapy and oral temozolamide for 30 wk total in cycles, followed by bevacizumab or placebo monotherapy. Outcomes were progression-free survival and overall survival.
**Results**: 458 patients in bevacizumab group, 463 patients in placebo. The median progression-free survival was longer in the bevacizumab group compared with placebo (10.6 mo vs. 6.2 mo, HR 0.64, 95% CI 0.55-0.74), although overall survival did not differ significantly between groups (HR 0.88, 95% CI 0.76-1.02). Baseline health-related QOL and performance status were maintained longer in the bevacizumab group although there was a higher frequency of adverse events.
**Conclusions**: The addition of bevacizumab to radiotherapy-temozolamide improves progression-free survival but not overall survival in patients with glioblastoma.

1. Homogenous contrast enhancement
2. Dural attachment
3. Distinct margins

**Figure 12. Meningioma on CT**

### Investigations
- **CT with contrast**: homogeneous, densely enhancing, along dural border ("dural tail"), well circumscribed, usually solitary (10% multiple, likely with loss of NF2 gene/22q12 deletion)
- **MRI with contrast**: characterization of mass and provides a better assessment of the patency of dural venous sinuses
- **angiography**
  - most are supplied by external carotid feeders (meningeal vessels)
  - can assess venous sinus involvement, "tumour blush" commonly seen (prolonged contrast image)

### Treatment
- **conservative management**: asymptomatic and/or non-progressive on CT/MRI – serial monitoring for interval growth changes
- **surgery**: curative if complete resection and indicated when symptomatic and/or documented growth on serial CT/MRI
- **endovascular**: embolization for highly vascularized, likely bloody, tumours to facilitate surgery
- **radiation**: SRS may be an option for lesions <3 cm partially occluding the superior sagittal sinus; SRS or XRT for non-resectable, recurrent atypical/malignant meningiomas

### Prognosis
- 5 yr survival is 7-25% for Grade I, 30-50% for Grade II, and 50-94% for Grade III
- depends on extent of resection
- Simpson's classification: degree of surgical resection completeness with symptomatic recurrence

**WHO Classification of Meningioma (by histology)**
Grade 1: low risk of recurrence
Grade 2: intermediate risk of recurrence
Grade 3: high risk of recurrence

**Recommendations for Management of Meningiomas**
Lancet Oncol 2016;17(9):e383-91
European Association of Neuro-Oncology assessed available literature and rated scientific evidence and graded recommendation levels.
Despite high frequency of meningiomas, evidence for diagnosis and treatment recommendation are low. Prospective studies to generate new evidence is required.
Key recommendations include:
1. First standard therapy is gross total surgical resection (including involved dura).
2. Alternative treatments include radiosurgery for small tumours and fractionated radiotherapy in large/previously treated tumours.
3. New treatment concepts combining surgery and radiosurgery/fractionated radiotherapy to treat complete tumour volume are being developed.
4. Although pharmacological treatments are still experimental, antiangiogenic drugs, peptide receptor radionuclide therapy, and targeted agents are candidates for future pharmacological approaches to treat refractory meningioma of all WHO grades.

## Vestibular Schwannoma (Acoustic Neuroma)

- slow-growing (60% show no growth over 1 yr; average rate for growing tumours 1-2 mm/yr), benign posterior fossa tumour (8-10% of tumours)
- arises from vestibular nerve of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of NF2
- epidemiology: 1.5/100,000; all age groups affected, peaks at 4th-6th decades

### Clinical Features
- **early clinical triad**: (tumour <2 cm) unilateral progressive hearing loss 98%, tinnitus, and disequilibrium (compression of CN VIII)
- **later clinical features**
  - tumour usually >2 cm: otalgia, facial numbness + weakness, changes to taste (due to CN V and VII compression, respectively)
  - tumour usually >4 cm: ataxia, H/A, N/V, diplopia, cerebellar signs (due to brainstem compression; ± obstructive hydrocephalus)

Progressive unilateral or asymmetrical sensorineural hearing loss = acoustic neuroma until proven otherwise

### Investigations
- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/specific); CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

### Treatment
- expectant: serial imaging (CT/MRI q6mo) and audiometry if tumour is small, hearing is still preserved, high perioperative risk, or elderly patient
- radiation: SRS or XRT
- surgery: if lesion >3 cm, brainstem compression, edema, hydrocephalus
- curable if complete resection (almost always possible)
- operative complications: CSF leak, meningitis, required shunt; CN V, VII, VIII dysfunction (proportional to tumour size; only significant CNVIII disability if bilateral)
- implications for testing of family members of NF2 mutation carrier

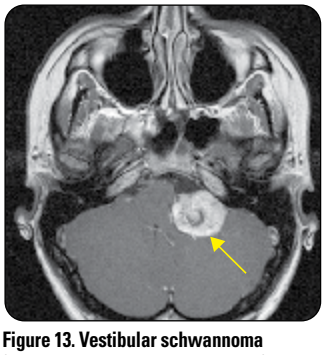


**Figure 13. Vestibular schwannoma** (tumour in cerebello-pontine angle)

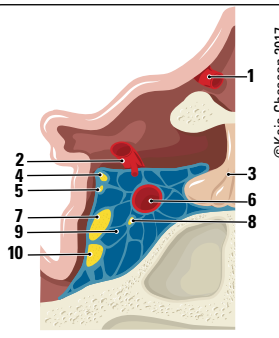
## Pituitary Adenoma

- primarily from anterior pituitary, 3rd-4th decades, M=F, associated with MEN-1 syndrome
- incidence in autopsy studies approximately 20%
- **classification**
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
  - most common functional: prolactinomas, adrenocorticotropic, growth-hormone (GH) producing
  - differential diagnosis: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm

**Go Look For The Adenoma Please – GH, LH, FSH, TSH, ACTH, Prolactin**
A compressive adenoma in the pituitary will impair hormone production in this order (i.e. GH-secreting cells are most sensitive to compression)



### Clinical Features
- mass effects
- H/A
- bitemporal hemianopsia (compression of optic chiasm); hydrocephalus (3rd ventricle compression)
- invasive adenomas: CN III, IV, V1, V2, VI palsy (cavernous sinus compression); proptosis and chemosis (cavernous sinus occlusion)
- endocrine effects (see Endocrinology, E20)
  - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido

- ACTH production: Cushing's disease, hyperpigmentation
- GH production: acromegaly/gigantism
- panhypopituitarism: due to compression of pituitary (hypothyroidism, hypoadrenalism, hypogonadism)
- DI – rare, except in apoplexy

- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
  - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, panhypopituitarism and DI
  - CSF rhinorrhea and seizures (rare)
  - signs and symptoms of SAH (rare)

### Investigations
- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolarity
- imaging (MRI with and without contrast)

### Treatment
- medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing's: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
- surgical
  - endoscopic trans-sphenoidal, trans-ethmoidal, and less commonly trans-cranial approaches (i.e. for significant suprasellar extension)
- post-operative concerns: DI, adrenal insufficiency (AI), CSF leak
  - DI and AI: AM cortisol, serum sodium and osmolality, urine output and specific gravity (treatment - AI: glucocorticoids; DI: desmopressin/DDAVP)
  - CSF rhinorrhea: test for β transferrin

1. Anterior cerebral artery
2. Internal carotid artery (cerebral part)
3. Pituitary gland
4. Oculomotor nerve
5. Trochlear nerve
6. Internal carotic artery (cavernous part)
7. Ophthalmic nerve
8. Abducent nerve
9. Cavernous sinus
10. Maxillary nerve

**Figure 14. Cavernous sinus**

### Genetic Associations
- Sellar masses have known associations with several classic oncogene mutations, including:
  - *MEN1*: loss-of-function mutations are common
  - Gs-alpha: activating mutations found in ~40% of somatotroph adenomas
  - AIP: mutations associated with familial pituitary adenomas

# Cerebral Abscess

### Definition
- pus in brain substance, surrounded by tissue reaction (capsule formation)

### Etiology
- modes of spread: 10-60% of patients have no cause identified
- pathogens
  - *Streptococcus* (most common), often anaerobic or microaerophilic
  - *Staphylococcus* (penetrating injury)
  - Gram-negatives, anaerobes (*Bacteroides, Fusobacterium*)
  - in neonates: *Proteus* and *Citrobacter* (exclusively)
  - immunocompromised: fungi and protozoa (*Toxoplasma, Nocardia, Candida albicans, Listeria monocytogenes, Mycobacterium*, and *Aspergillus*)

### Sources of Pus/Infection
- four routes of microbial access to CNS
  1. hematogenous spread: arterial and retrograde venous
     - adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
     - children: congenital cyanotic heart disease with R-to-L shunt
     - immunosuppression (AIDS – toxoplasmosis)
  2. direct implantation (dural disruption)
     - trauma
     - iatrogenic (e.g. following LP, post-operative)
     - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site (e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess)
  4. spread from PNS (e.g. viruses: rabies, herpes zoster)
- common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
    - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
    - treatment: surgical drainage and antibiotics, 20% mortality
  - meningitis, encephalitis (see Infectious Diseases, ID15)
  - cerebral abscess

### Risk Factors
- lung abnormalities (infection, AVFs; especially Osler-Weber-Rendu syndrome [i.e. hereditary hemorrhagic telengiectasia])
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess, poor dentition

### Clinical Features
- focal neurological signs and symptoms
  - H/A, decreased LOC; hemiparesis and seizures in 50%
- mass effect, increased ICP and sequelae (cranial enlargement in children)
- hemiparesis and seizures in 50%
- ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

### Complications
- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

### Investigations
- CT scan often first test in emergency department
- MRI
  - imaging of choice
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
- WBC/ESR may be normal, blood cultures rarely helpful and LP contraindicated if large mass
- CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

### Treatment
- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), C&S, fungal culture
- excision preferable if location suitable
- antibiotics
  - empirically: vancomycin + ceftriaxone + metronidazole or chloramphenicol or rifampin (6-8 wk therapy)
  - revise antibiotics when C&S known
- anti-convulsants (1-2 yr)
- follow-up CT is critical (do weekly initially, more frequent if condition deteriorates)

### Prognosis
- mortality with appropriate therapy ~10%, permanent deficits in ~50%

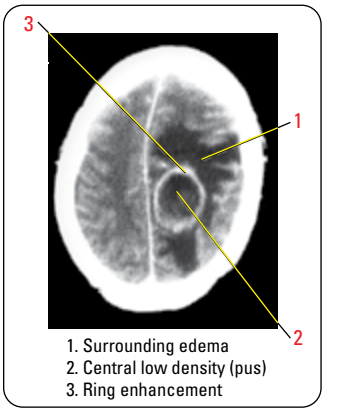


**Figure 15. Cerebral abscess on CT**

**Recommendations for Duration of Antibiotic Therapy for Brain Abscesses**
Int J Infect Dis 2010;14 Suppl 4:S79-92
**Summary:**
1. Prudent period of 4-6 weeks of antibiotic therapy for surgically treated abscesses.
2. 6-8 weeks of IV treatment for abscesses treated medically only.
3. 6-8 weeks of IV treatment for multiple abscesses when larger ones are treated surgically.
**Methods**: Systematic literature search using MEDLINE database for studies during 1988-2008 to methodologically evaluate all studies pertaining to brain abscess.
**Results**: Several recommendations were made by extracting evidence; for duration of antibiotic therapy, it was noted that IV antibiotic therapies were usually ≥4 weeks. No studies have evaluated the duration of antibiotic therapy on outcome. Without evidence to safely evaluate endovenous therapy time, authors agreed with British Society for Antimicrobial Chemotherapy recommendations (see summary).

# Blood

**Table 10. Comparison of Epidemiology and Etiology of Intracranial Bleeds**

| Types of Hematoma/ Hemorrhage | Etiology | Epidemiology | Clinical Features | CT Features | Treatment | Prognosis |
|---|---|---|---|---|---|---|
| **Epidural Hematoma** | Skull fracture causing middle meningeal bleed | M>F (4:1), associated with trauma | Lucid interval before LOC | Hyperdense lenticular mass with sharp margins, usually limited by suture lines | Craniotomy | Good with prompt management (Note: respiratory arrest can occur from uncal herniation) |
| **Acute SDH** | Ruptured subarachnoid bridging vessels | Age >50, associated with trauma | No lucid interval, hemiparesis, pupillary changes | Hyperdense crescentic mass, crossing suture lines | Craniotomy if bleed >1 cm thick | Poor |
| **Chronic SDH** | Ruptured subarachnoid bridging vessels | Age >50, EtOH abusers, anticoagulated | Often asymptomatic, minor H/A, confusion, signs of increased ICP, llight-headedness | Hypodense crescentic mass, crossing suture lines | Burr hole to drain; craniotomy if recurs | Good |
| **SAH** | Trauma, spontaneous (aneurysms, idio-pathic, AVM) | Age 55-60, 20% cases under age 45 | Sudden onset thunderclap H/A, signs of increased ICP | Hyperdense blood in cisterns/fissures (sensitivity decreases over time) | Conservative: NPO, IV NS, ECG, Foley, BP 120-150, vasospasm prophylaxis (nimodipine); open vs. endovascular surgery to repair if rebleed | Poor: 50% mortality; 30% of survivors have moderate to severe disability |
| **ICH** | HTN, vascular abnormality, tumours, infections, coagulopathy | Age >55, male, drug use (cocaine, EtOH, amphetamine) | TIA-like symptoms, signs of increased ICP | Hyperdense intra-parenchymal collection | Medical: decrease BP, control ICP<br>Surgical: craniotomy | Poor: 44% mortality due to cerebral herniation |

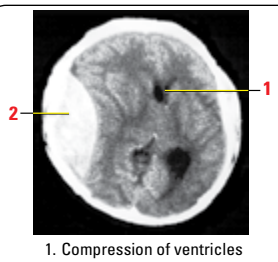
**CT Density and MRI Appearance of Blood**

| Time | CT | MRI T1 | MRI T2 |
|---|---|---|---|
| Acute (<72 h) | Hyper. | Grey | Black |
| Subacute (<3 wk) | Iso. | White | White |
| Chronic (>3 wk) | Hypo. | Black | Black |

MRI-T1: "**G**eorge **W**ashington **B**ridge"
MRI-T2: "Oreo" cookie – **B**lack/**W**hite/**B**lack

# Extradural ("Epidural") Hematoma

## Etiology
- temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins



## Epidemiology
- young adult, M>F = 4:1; rare before age 2 or after age 60
- 1-4% of traumatic head injuries

## Clinical Features
- classic sequence (seen in <30%): post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
- signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, aphasia, seizures, HTN, and respiratory distress
- deterioration can take hours to days

## Investigations
- CT without contrast: "lenticular-shaped" usually limited by suture lines but not limited by dural attachments (not visible on initial CT in 8% of cases)

## Treatment
- admission, close neurological observation with serial CT indicated if all of the following are present
  - small volume clot (<30 mL), clot thickness <15 mm, minimal midline shift (MLS <5 mm), GCS >8, no focal deficit
- otherwise, urgent craniotomy to evacuate clot, follow-up CT
- patients with initial EDH >10 mL on CT within 2 h or EDH in temporoparietal region are more likely to develop epidural hematoma enlargement and require close CT follow-up at 5-6 h post impact
- mannitol pre-operative if elevated ICP or signs of brain herniation
- reverse anticoagulation if on warfarin

## Prognosis
- good with prompt management, as the brain is often not damaged
- worse prognosis if bilateral Babinski or decerebration pre-operative
- death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

1. Compression of ventricles (midline shift)
2. Blood

**Figure 16. Extradural hematoma on CT**

**Poor Prognostic Indicators for Epidural Hematoma**
- Older age
- Low GCS on admission
- Pupillary abnormalities (especially non-reactive)
- Longer delay in obtaining surgery (if needed)
- Post-operative elevated ICP

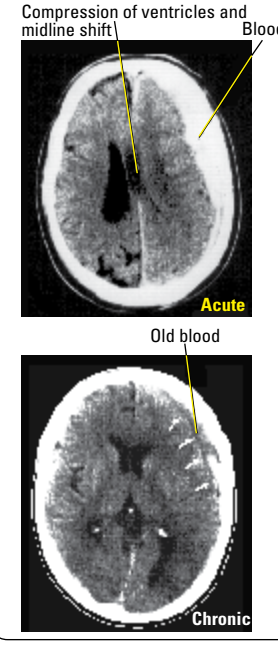


**Figure 17. Subdural hematoma on CT**

# Subdural Hematoma

**Table 11. Comparison of Epidemiology and Etiology of Acute and Chronic SDH**

| | Acute SDH | Chronic SDH |
|---|---|---|
| **Time Course** | 1-2 d after bleeding onset | ≥15 d after bleeding onset |
| **Etiology** | Rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration | Many start out as acute SDH<br>Blood within the subdural space evokes an inflammatory response:<br>Fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot (forming a hygroma)<br>Course is determined by the balance of rebleeding from neomembranes and resorption of fluid |
| **Risk Factors** | Trauma, acceleration-deceleration injury, anticoagulants, alcohol, cerebral atrophy, infant head trauma | Older, alcoholics, patients with CSF shunts, anticoagulants, coagulopathies |
| **Clinical Features** | Signs and symptoms can include: altered LOC, pupillary irregularity, hemiparesis<br>Up to 50% of patients can present with coma from the time of injury | Often due to minor injuries or no history of injury<br>May present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ± seizures, progressive dementia, gait problem, light-headedness<br>Presents with global rather than focal deficits, such as disturbance of consciousness; "the great imitator" of dementia, tumours |
| **Investigations** | CT: Hyperdense concave "crescentic" mass, crossing suture lines | CT: hypodense (liquefied clot), crescentic mass |
| **Treatment** | Indications for craniotomy:<br>- if clinically symptomatic, hematoma >1 cm thick, MLS >5 mm, GCS decreased by >2 from time of injury to hospital admission, or ICP persistently >20 mmHg (optimal if surgery <4 h from onset)<br>Otherwise observe with serial imaging if stable or improving | Seizure prophylaxis only if post-traumatic seizure<br>Reverse coagulopathies<br>Burr hole drainage of liquefied clot indicated if symptomatic or thickness >1 cm; craniotomy if recurs more than twice |
| **Prognosis** | Poor overall since the brain parenchyma is often injured (mortality range is 50-90%, due largely to underlying brain injury)<br>Prognostic factors: initial GCS and neurological status, post-operative ICP | Good overall as brain usually undamaged, but may require repeat drainage |

**Use of Drains Vs. No Drains After Burr-Hole Evacuation For Treatment of Chronic Subdural Hematoma**
Cochrane Database Syst Rev. 2016;(8):CD011402
**Summary**:
1. Some evidence that post-operative drainage is effective in reducing the symptomatic recurrence of chronic subdural hematoma
2. The effect of drainage on the occurrence of surgical complications, mortality, and poor functional outcomes is uncertain due to low quality evidence
3. No strong evidence of increase in complications when drains are used

**Methods**: Comprehensive search strategy databases extracting 9 RCTs (n=968) comparing external subdural drains with no drains after burr-hole evacuation for treatment of chronic subdural hematoma.
**Results**: Significant reduction in the risk of recurrence with subdural drains (RR 0.45, 95% CI 0.32-0.61), no strong evidence of increase in complications (RR 0.78, 95% CI 0.77-1.72), mortality (RR 0.78, 95% CI–0.45-1.33), poor functional outcome (RR 0.68, 95% CI 0.44-1.05).

# Cerebrovascular Disease

**Cerebrovascular disease may be divided into two general categories:**

### Ischemic Cerebral Infarction (80% of disease)
- includes embolism, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc. (see Neurology, N48)

### Intracranial Hemorrhage (20% of disease)
- includes SAH, spontaneous ICH, IVH
- may occur due to ruptured intracranial aneurysms

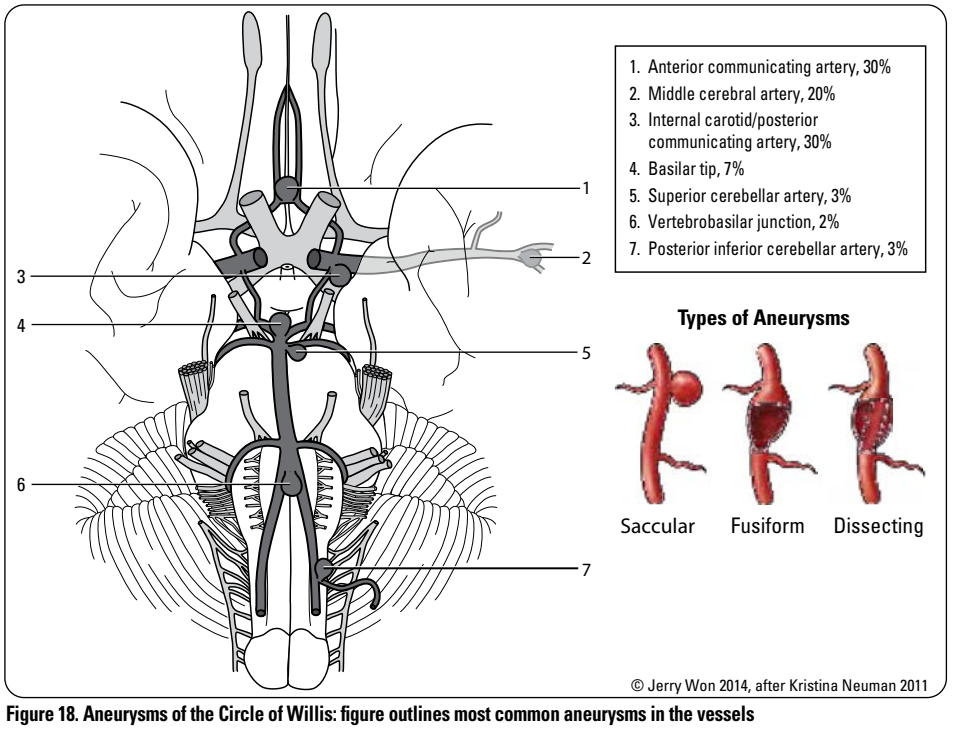

**Figure 18. Aneurysms of the Circle of Willis: figure outlines most common aneurysms in the vessels**

**Hemicraniectomy in Older Patients with Extensive Middle-Cerebral-Artery Stroke**
NEJM 2014;370:1091-1100
**Purpose**: To determine if early decompressive hemicraniectomy reduces mortality among patients >60 yr.
**Study**: 112 patients >60 yr (median age 70 yr) with malignant MCA infarction randomly assigned to conservative ICU treatment versus hemicraniectomy. Endpoint was survival without severe disability (modified Rankin scale score 0-4).
**Results**: The proportion of patients who survived without severe disability was 38% in the hemicraniectomy group and 18% in the control group (OR 2.91, 95% CI 1.06-7.49). Modified Rankin scale scores in hemicraniectomy versus control group in terms of percentages of patients: 0-2 (0%, 0%), 3 or moderate disability (7%, 3%), 4 or moderate severe disability (32%, 15%), 5 or severe disability (28%, 13%) and 6 or death (33%, 70%). Infections were more frequent in the hemicraniectomy group and herniation more frequent in the control group.
**Conclusions**: Hemicraniectomy increased survival without severe disability among patients >60 yr with a malignant MCA infarction.

# Subarachnoid Hemorrhage

### Definition
- bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

### Etiology
- trauma (most common)
- spontaneous
  - ruptured aneurysms (75-80%)
  - idiopathic (14-22%)
  - AVMs (4-5%)
- coagulopathies (iatrogenic or primary), vasculitides, tumours, cerebral artery dissections (<5%)

### Epidemiology
- ~10-28/100,000 population/yr
- peak age 55-60, 20% of cases occur under age 45

### Risk Factors
- HTN
- pregnancy/parturition in patients with pre-existing AVMs, eclampsia
- oral contraceptive pill
- substance abuse (cigarette smoking, cocaine, alcohol)
- conditions associated with high incidence of aneurysms (see *Intracranial Aneurysms*, NS20)

### Clinical Features of Spontaneous SAH
- sudden onset (seconds) of severe "thunderclap" H/A usually following exertion and described as the "worst headache of my life" (up to 97% sensitive, 12-25% specific)
- N/V, photophobia
- meningismus (neck pain/stiffness, positive Kernig's and Brudzinski's sign)
- decreased LOC (due to either raised ICP, ischemia, or seizure)

**Hunt and Hess Grade (clinical grading scale for SAH)**

| Grade | Description |
|---|---|
| 1 | No Sx or mild H/A and/or mild meningismus |
| 2 | Grade 1 + CN palsy |
| 3 | Confusion/lethargy, mild hemiparesis, or aphasia |
| 4 | GCS <15 but >8, moderate-severe hemiparesis, mild rigidity |
| 5 | Coma (GCS <9), decerebrate, moribund appearance |

Mortality of Grade 1-2 20%, increased with grade

- focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
- ocular hemorrhage in 20-40% (due to sudden raised ICP compressing central retinal vein)
- reactive HTN
- sentinel bleeds
  - represents undiagnosed SAH
  - SAH-like symptoms lasting <1 d ("thunderclap H/A")
  - may have blood on CT or LP
  - ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
- differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

## Investigations

- non-contrast CT – for diagnosis of SAH
  - 98% sensitive within 12 h, 93% within 24 h; 100% specificity
  - may be negative if small bleed or presentation delayed several days
  - acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
- LP (highly sensitive) – for diagnosis of SAH if CT negative but high suspicion:
  - elevated opening pressure (>18 cm $H_2O$)
  - bloody initially, xanthochromic supernatant with centrifugation ("yellow") by ~12 h, lasts 2 wk
  - RBC count usually >100,000/mm3 without significant drop from first to last tube (in contrast to traumatic tap)
  - elevated protein due to blood breakdown products
- four vessel cerebral angiography ("gold standard" for aneurysms)
  - demonstrates source of SAH in 80-85% of cases
  - angiogram negative SAH: repeat angiogram in 7-14 d, if negative → "perimesencephalic SAH"
- MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

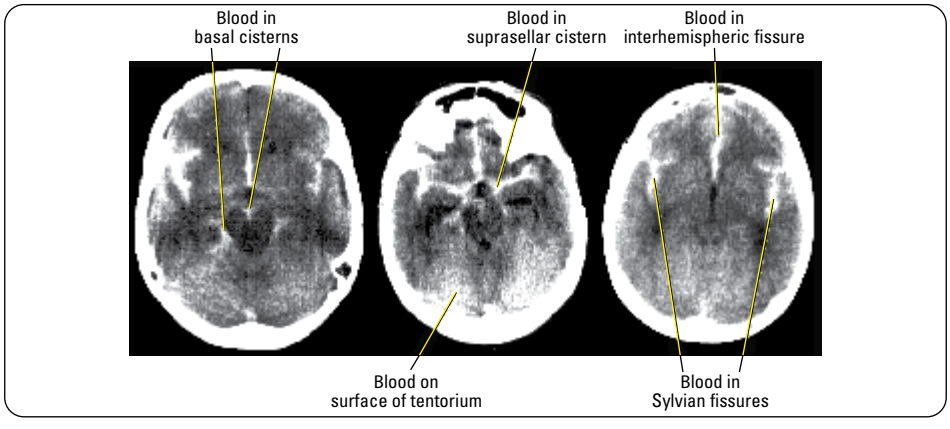

**Figure 19. Diagnosis of SAH**

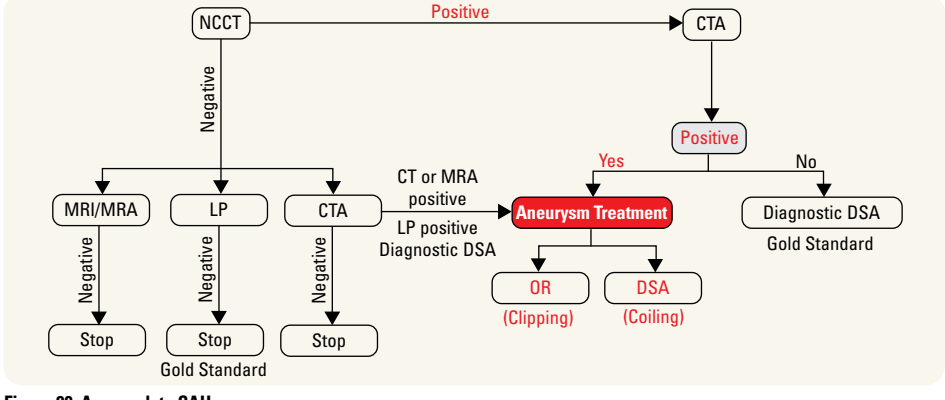

**Figure 20. Approach to SAH**
Adapted from: de Oliveira Manoel et al. (2014) Subarachnoid haemorrhage from a neuroimaging perspective. Critical Care

## Treatment

- admit to ICU or NICU
  - oxygen/ventilation prn
  - NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
  - aim to maintain sBP = 120-150 (balance of vasospasm prophylaxis, risk of rebleed, risk of hypotension since CBF autoregulation impaired by SAH)
  - cardiac rhythm monitor, Foley prn, strict monitoring of ins and outs

**World Federation of Neurological Surgeons Grading of SAH**

| WFNS Grade | GCS Score | Aphasia, Hemiparesis, or Hemiplegia |
|---|---|---|
| 0 * | | |
| 1 | 15 | – |
| 2 | 13-14 | – |
| 3 | 13-14 | + |
| 4 | 7-12 | + or – |
| 5 | 3-6 | + or – |

*Intact aneurysm

**Nontraumatic Subarachnoid Hemorrhage in the Setting of Negative Cranial Computed Tomography Results: External Validation of a Clinical and Imaging Prediction Rule**
Ann Emerg Med 2012;59:460-8.e1-7.doi:10.1016
**Background**: Two rules for SAH diagnosis exist. A clinical prediction rule states that patients with acute severe H/A but without the clinical variables age ≥40 yr, neck pain, LOC, or onset of H/A with exertion are at low risk for SAH. An imaging prediction rule bases diagnosis on non-contrast cranial CT for patients within 6 h of H/A onset.
**Methods**: Matched case-control study of 55 patients at 21 emergency departments between 2000 and 2011, and diagnoses were verified by LP.
**Results**: The clinical prediction rule for diagnosis of SAH was 97.1% sensitive, 22.7% specific, and had a negative likelihood ratio of 0.13. Using the imaging prediction rule resulted in a false negative rate of 20%.
**Conclusions**: Performing the clinical and imaging rules together has the potential for maximizing sensitivity of prediction and reducing rates of LP, but using imaging alone can result in missed cases.

**The Vasograde: A Simple Grading Scale For Prediction Of Delayed Cerebral Ischemia After Subarachnoid Hemorrhage**
Stroke 2015; 46(7):1826-31
**Background**: Patients are classically at risk of delayed cerebral ischemia (DCI) after aneurysmal SAH. We validated a grading scale – the VASOGRADE – for prediction of DCI.
**Method**: We used data of 3 phase II RCT and a single hospital series to assess the relationship between the VASOGRADE and DCI.
**Results**: In a cohort of 746 patients, the VASOGRADE signicantly predicted DCI (P<0.001). The VASOGRADE-Yellow had a tendency for increased risk for DCI (odds ratio [OR], 1.31; 95% CI, 0.77–2.23) when compared with VASOGRADE- Green; those with VASOGRADE-Red had a 3-fold higher risk of DCI (OR, 3.19; 95% CI, 2.07–4.50). VASOGRADE had an adequate discrimination for prediction of DCI (area under the receiver operating characteristics curve=0.63) and good calibration.
**Conclusions**: The VASOGRADE results validated previously published risk charts in a large and diverse sample of SAH patients, which allows DCI risk stratification on presentation after SAH. It could help to select patients at high risk of DCI, as well as standardize treatment protocols and research studies.

**The VASOGRADE**: A simple grading scale for prediction of delayed cerebral ischemia after SAH
*Stroke* 2015;46: 1826-1831

- medications
  - IV NS with 20 mmol KCl/L at 125-150 cc/h
  - nimodipine 60 mg PO/NG q4h x 21 d for delayed cerebral ischemia neuroprotection; may discontinue earlier if patient is clinically well
  - seizure prophylaxis: levetiracetam (Keppra®) 500 mg PO/IV q12h x 1 wk
  - mild sedation prn
  - neuroprotection
  - the only validated neuroprotective agent is nimodipine
  - studies on the use of IV magnesium and endothelin-A antagonist (clazosentan) showed reduction in DCI and vasospasm, respectively, without any effect on functional outcome
  - a trial on the use of statins did not show any neuroprotective benefit

**VASOGRADE**

| VASOGRADE | WFNS | Modified Fischer scale |
|---|---|---|
| **Green** | 1-2 | 1-2 |
| **Yellow** | 1-3 | 3-4 |
| **Red** | 4-5 | Any |

### Complications

- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood – can lead to delayed cerebral ischemia and death
  - onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
  - clinical features (new onset ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor e.g. pronator drift)
  - risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
  - "symptomatic" vasospasm in 20-30% of SAH patients
  - "radiographic" vasospasm in 30-70% of arteriograms performed 7 d following SAH
  - diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
  - risk of cerebral infarct and death
  - treatment
    - hyperdynamic ("triple H") therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
    - direct vasodilation via angioplasty or intra-arterial verapamil for refractory cases
- delayed cerebral ischemia: neurological deterioration persisting more than 1 h in the absence of any obvious contributing physiological, radiological or laboratory abnormalities
  - peaks 4-10 d post ictus
  - can progress to cerebral infarction and is associated with significant morbidity and mortality
  - mechanism behind DCI is unclear but includes vasospasm, vascular dysautoregulation, neurotoxic effects from the blood, inflammation, micro-thrombi and cortical spreading depolarizations
  - it is an essential target for SAH management
- hydrocephalus (15-20%): due to blood obstructing arachnoid granules
  - can be acute or chronic, requires extraventricular drain or shunt, respectively
- neurogenic pulmonary edema
- hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECF volume loss), not SIADH
- DI
- cardiac: arrhythmia (>50% have ECG changes), MI, CHF

**Long-Term Risk of Recurrent Subarachnoid Hemorrhage, Death, Dependence and Standardized Mortality Ratios After Clipping or Coiling of an Intracranial Aneurysm (ISAT)**
Lancet 2015 Feb 21; 385(9969): 691–697
**Summary:**
1. The probability of death or dependency was significantly greater in the neurosurgical group (vs. endovascular group) at 10 year FU.
2. Rebleeding was more likely in endovascular group (vs. neurosurgical group), but risk was small at 10 year FU.
3. Probability of disability free survival was significantly greater in the endovascular group (vs. neurosurgical group) at 10 year FU.

**Methods**: RCT comparing endovascular coiling treatment with craniotomy and clipping for ruptured intracranial aneurysms in 2143 patients who were considered eligible for either modality or therapy between 1994-2002. 1644 patients were followed for deaths and outcomes for 10-18.5 years.
**Results**: At 10 years, 83% of endovascular coiling group and 79% of neurosurgical clipping group were alive. 82% of patients treated with endovascular coiling and 78% of patients treated with neurosurgical clipping were independent. Patients in the endovascular group were more likely to be alive and independent at 10 years vs. neurosurgery group (OR 1.34, 95% CI 1.07-1.67). Rebleeding risks from target aneurysm for endovascular group and neurosurgery group were 0.0216 (95% CI 0.0121-0.0383) and 0.0064 (95% CI 0.0024-0.0173), respectively.

### Prognosis

- 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
- 30% of survivors have moderate to severe disability
- a major cause of mortality is rebleeding, for untreated aneurysms:
  - risk of rebleed: 4% on 1st day, 15-20% within 2 wk, 50% by 6 mo
  - if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
  - only prevention is early clipping or coiling of "cold" aneurysm
  - rebleed risk for "perimesencephalic SAH" is approximately same as for general population

## Intracranial Aneurysms

### Epidemiology

- prevalence 1-4% (20% have multiple)
- F>M; age 35-65 yr (mean age of presentation is 50 years old)

**Commonest Locations of Saccular Aneurysms**
- AComm: 30%
- PComm: 25%
- MCA: 20%
- Basilar tip: 7%

### Types

- saccular (berry)
  - most common type
  - located at branch points of major cerebral arteries (Circle of Willis)
  - 85-95% in carotid (anterior) system, 5-15% in vertebrobasilar (posterior) circulation
- fusiform
  - atherosclerotic
  - more common in vertebrobasilar system, rarely rupture
- infectious
  - secondary to any infection of vessel wall, 20% multiple
  - 60% *Streptococcus* and *Staphylococcus*
  - 3-15% of patients with bacterial endocarditis

## Risk Factors

- autosomal dominant polycystic kidney disease (15%)
- fibromuscular dysplasia (7-21%)
- AVMs
- connective tissue diseases (Ehlers-Danlos, Marfan)
- family history
- bacterial endocarditis
- Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
- atherosclerosis and HTN
- trauma

**Risk Factors for Saccular (Berry) Aneurysms**
**S**moking
**H**ypetension
**A**dult Polycystic Kidney Disease
**E**hlers-Danlos Syndrome

**Table 12. Five Year Cumulative Rupture Risk in Unruptured Aneurysms Based on Size and Location**

| | Cavernous Carotid | AC/MC/IC | Vertebrobasilar/PC/PComm |
|---|---|---|---|
| **<7 mm** | 0% | 0% | 2.5% |
| **7-12 mm** | 0% | 2.6% | 14.5% |
| **13-24 mm** | 3% | 14.5% | 18.4% |
| **≥24 mm** | 6.4% | 40% | 50% |

AC = anterior cerebral/anterior communicating artery; IC = internal carotid artery; MC = middle cerebral artery; PC = posterior cerebral artery; PComm = posterior communicating artery.
Lancet 2003;362:103-110

**Long-Term, Serial Screening for Intracranial Aneurysms in Individuals with a Family History of Aneurysmal Subarachnoid Hemorrhage: A Cohort Study**
Lancet Neurol 2014;13:385-392
**Purpose**: To examine the yield of long-term serial screening for intracranial aneurysms for individuals with a positive family history of aneurysmal subarachnoid hemorrhage (aSAH) (two or more first degree relatives who have had aSAH or unruptured intracranial aneurysms).
**Study**: Screening results from April 1 1993 to April 1 2013 were reviewed in a cohort study. MRA or CTA was done from age 16-18 to 65-70 yr. After a negative screen, individuals were advised to contact the clinic in 5 yr for follow-up.
**Results**: Aneurysms were identified in 11% of individuals at first screening (n=458), 8% at second screening (n=261), 5% at third screening (n=128), and 5% at fourth screening (n=63). Smoking (OR 2.7, 95% CI 1.2-5.9), history of previous aneurysms (3.9, 1.2-12.7), and familial history of aneurysms (3.5, 1.6-8.1) were significant risk factors for aneurysm at first screening. History of previous aneurysms was the only significant risk factor for aneurysms at follow-up screening (HR 4.5, 95% CI 1.1-18.7).
**Conclusions**: The benefit of long-term screening in individuals with a family history of aSAH is substantial up to and after 10 yr of follow-up and two initial negative screens.

## Clinical Feature

- rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
- sentinel hemorrhage ("thunderclap H/A") → requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
  - internal carotid or anterior communicating aneurysm may compress:
    - the pituitary stalk or hypothalamus causing hypopituitarism
    - the optic nerve or chiasm producing a visual field defect
    - basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
    - posterior communicating artery aneurysm may produce CN III palsy
    - intracavernous aneurysms (CN III, IV, V1, V2, VI)
- distal embolization (e.g. amaurosis fugax)
- seizures
- H/A (without hemorrhage)
- incidental CT or angiography finding (asymptomatic)

## Investigations

- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

## Treatment

- **ruptured aneurysms**
  - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
    - treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling) or flow diversion stents, wrapping (last resort)
  - choice of surgery vs. coiling not yet well defined: consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition; in general:
    - coiling: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    - clipping: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
- **unruptured aneurysms**
  - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
  - no clear evidence on when to operate: need to weigh life expectancy
  - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
  - generally treat unruptured aneurysms >10 mm
  - consider treating when aneurysm 7-9 mm in middle-aged, younger patients, or patients with a family history of aneurysms
  - follow smaller aneurysms with serial angiography

**The Unruptured Intracranial Aneurysm Treatment Score**
Neurology 2015;85(10):881-9
**Objective**: to develop an unruptured intracranial aneurysm (UIA) treatment score (UIATS) model that includes and quantifies key factors involved in clinical decision-making in the management of UIAs and to assess agreement for this model among specialists in UIA management and research.
**Methods**: An international multidisciplinary (neurosurgery, neuroradiology, neurology, clinical epidemiology) group of 69 specialists was convened to develop and validate the UIATS model using a Delphi consensus method.
**Results**: The UIATS accounts for 29 key factors in UIA management.
**Conclusions**: This novel UIA decision guidance study captures an excellent consensus among highly informed individuals on UIA management, irrespective of their underlying specialty.

# Intracerebral Hemorrhage

## Definition
- hemorrhage within brain parenchyma, accounts for ~10% of strokes
- can dissect into ventricular system (IVH) or through cortical surface (SAH)

## Etiology
- HTN (usually causes bleeds at putamen, thalamus, pons, and cerebellum)
- hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
- vascular anomalies
  - aneurysm, AVMs, and other vascular malformations (see *Vascular Malformations*, NS23)
  - venous sinus thrombosis
  - arteriopathies (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
- tumours (1%): often malignant (e.g. glioblastoma multiforme, lymphoma, metastases)
- drugs (amphetamines, cocaine, alcohol, anticoagulants, etc.)
- coagulopathy (iatrogenic, leukemia, thrombotic thrombocytopenic purpura, aplastic anemia)
- CNS infections (fungal, granulomas, herpes simplex encephalitis)
- post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contrecoup mechanism)
- eclampsia
- post-operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
- idiopathic

## Epidemiology
- 12-31 cases/100,000 population/yr

## Risk Factors
- increasing age (mainly >55 yr)
- male gender
- HTN
- Black/Asian > Caucasian
- previous CVA of any type (23x risk)
- both acute and chronic heavy alcohol use; cocaine, amphetamines
- liver disease
- anticoagulants

## Clinical Features
- TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
- gradual onset of symptoms over minutes-hours, usually during activity
- H/A, N/V, and decreased LOC are common
- specific symptoms/deficits depend on location of ICH

## Investigations
- baseline severity score such as the ICH Score should be performed as part of the initial workup
- hyperdense blood on non-contrast CT
- CTA routine, if spot sign (contrast in the hematoma) demonstrated there is high likelihood of clot growth

## Treatment
- patients should be transferred to and managed in a neuro-ICU or stroke unit
- **medical**
  - decrease MAP to pre-morbid level or by ~20% (target BP 140/90) in ED
  - check PTT/INR, and correct coagulopathy (immediate reversal of anticoagulation)
  - control raised ICP (see *Intracranial Pressure Dynamics*, NS4)
  - corticosteroids should NOT be used for elevated ICP in ICH
  - levetiracetam/phenytoin for seizure prophylaxis
  - follow electrolytes (SIADH common)
  - angiogram to rule out vascular lesion unless >45 yr, known HTN, and putamen/thalamic/posterior fossa ICH (yield ~0%)
- **surgical**
  - craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumour, cavernoma), ventriculostomy to treat hydrocephalus
  - indications
    - symptoms of raised ICP or mass effect
    - rapid deterioration (especially if signs of brainstem compression)
    - favourable location (e.g. cerebellar, non-dominant hemisphere)
    - young patient (<50 yr)
    - if tumour, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
  - contraindications
    - small bleed: minimal symptoms, GCS >10
    - poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
    - medical reasons (e.g. very elderly, severe coagulopathy, difficult location [e.g. basal ganglia, thalamus])

**Location of ICH**
Basal Ganglia/Internal Capsule (50%)
Thalamus (15%)
Cerebral White Matter (15%)
Cerebellum/Brainstem – usually pons (15%)
Other (5%)

**ICH Score Components**
- GCS score (3-4 = 2 pts; 5-12=1 pt, 13-15=0 pt)
- ICH volume (≥30 cm= 1 pt, <30 cm= 0 pt)
- Presence of IVH (yes=1 pt, no=0 pt)
- Infratentorial origin (yes=1 pt, no=0 pt)
- Age (≥80 = 1 pt, <80 = 0 pt)

**Early Surgery vs. Initial Conservative Treatment in Patients with Spontaneous Supratentorial Lobar Intracerebral Hematomas (STICH-II): A Randomized Trial**
Lancet 2013 382(9890): 397-408
**Summary**: The STICH II (international, parallel-group trial comparing early surgical hematoma evacuation within 12 hour of randomization and medical treatment vs. initial medical treatment alone) results confirm that early surgery does not increase the rate of death or disability at 6 mo and might have a small but clinically relevant survival advantage for patients with spontaneous superficial intracerebral haemorrhage without intraventricular haemorrhage.

**Spetzler-Martin AVM Grading Scale**

| Item | Score |
|---|---|
| **Size** | |
| 0-3 cm | 1 |
| 3.1-6.0 cm | 2 |
| >6 cm | 3 |
| **Location** | |
| Noneloquent | 0 |
| Eloquent | 1 |
| **Deep Venous Drainage** | |
| Not present | 0 |
| Present | 1 |

AVM grades calculated by adding the 3 individual Spetzler-Martin Scale scores from the above table. e.g. a 2 cm tumour in noneloquent location without deep venous drainage = Grade I

### Prognosis
- 30 d mortality rate 44%, mostly due to cerebral herniation
- rebleed rate 2-6%, higher if HTN poorly controlled

# Vascular Malformations

### Types
- AVMs
- cavernous malformations (cavernomas, cavernous hemangiomas/angiomas)
- venous angioma
- capillary telangiectasias
- AVF (carotid-cavernous fistula, dural AVF, vein of Galen aneurysm)
- "angiographically occult vascular malformations" (any type, 10% of malformations)

## Arteriovenous Malformations, Cavernous Malformations, and Dural Fistulas

**Table 13. Comparison of Pathoetiology, Clinical Feature, and Treatment of Arteriovenous Malformations, Cavernous Malformations, and Dural Fistulas**

| | Arteriovenous Malformation | Cavernous Malformations | Dural Fistulas |
|---|---|---|---|
| **Definition** | Tangle of abnormal vessels/arteriovenous shunts, with no intervening capillary beds or brain parenchyma; usually congenital | Benign vascular hamartoma consisting of irregular sinusoidal vascular channels located within the brain without intervening neural tissue or associated large arteries/veins<br>Several genes now described: CCM1, CCM2, CCM3 | Fistula's connecting dural arteries to dural veins or the dural sinus<br>Frequently described to occur at the transverse and cavernous sinuses, but can be found at every cranial dural sinus<br>Hypothesized to be related to venous sinus thrombosis formation, and subsequent microvascular shunt formation within the dura between arteries and veins |
| **Epidemiology** | Prevalence ~0.14%, M:F = 2:1, average age at diagnosis = 33 yr<br>15-20% of patients with hereditary hemorrhagic telengiectasia (Osler-Weber-Rendu syndrome) will have cerebral AVMs | Prevalence of 0.1-0.2%, both sporadic and hereditary forms described | Unknown true incidence<br>Constitute 10-15% of all intracranial vascular abnormalities |
| **Clinical Features** | Hemorrhage (40-60%): small AVMs are more likely to bleed due to direct high pressure AV connections<br>Seizures (50%): more common with larger AVMs<br>Mass effect<br>Focal neurological signs secondary to ischemia (high flow → "steal phenomena")<br>Localized headache, increased ICP<br>Bruit (especially with dural AVMs)<br>May be asymptomatic ("silent") | Seizures (60%), progressive neurological deficit (50%), hemorrhage (20%), H/A<br>Often an incidental finding<br>Hemorrhage risk less than AVM, usually minor bleeds | Asymptomatic, pulsatile tinnitus if involving sigmoid or transverse sinuses, bruits, H/A<br>Carotid cavernous involvement classically produces proptosis, chemosis, and bruits<br>Symptoms of SAH, SDH, or ICH |
| **Investigations** | MRI (flow void), MRA<br>Angiography (7% will also have one or more associated aneurysms) | T2WI MRI (non-enhancing)<br>Gradient echo sequencing (best for diagnosis) | Non-enhanced CT to r/o hemorrhage<br>MRI; however, this does not demonstrate the arterial supply to the fistula<br>Angiography remains the gold standard |
| **Treatment** | Decreases risk of future hemorrhage and seizure<br>Surgical excision is treatment of choice even in Spetzler-Martin Grades I – II with general good health<br>SRS is preferred for small (<3 cm) or very deep lesions<br>Endovascular embolization (glue, balloon) can be curative (5%) or used as adjuvant to surgery or SRS in larger lesions<br>Conservative (e.g. palliative embolization, seizure control if necessary) | Surgical excision:<br>Only appropriate for symptomatic lesions that are surgically accessible (supratentorial lesions are less likely to bleed than infratentorial lesions) | Approach is dependent on size, location and symptoms, and includes:<br>Conservative treatment<br>Neuroradiological endovascular interventions<br>Radiation therapy<br>Surgery<br>Combination of the above |
| **Prognosis** | 10% mortality, 30-50% morbidity (serious neurological deficit) per bleed<br>Risk of major bleed in untreated AVMs: 2-4%/yr | Annual bleeding rates: 0.25-1.1% for supratentorial, 2-3% for brainstem<br>Symptomatic lesions have a higher hemorrhage risk than asymptomatic | 8.1% annual risk of hemorrhage<br>6.9% annual risk for non-hemorrhagic neurological deficit<br>10.4% mortality rate |

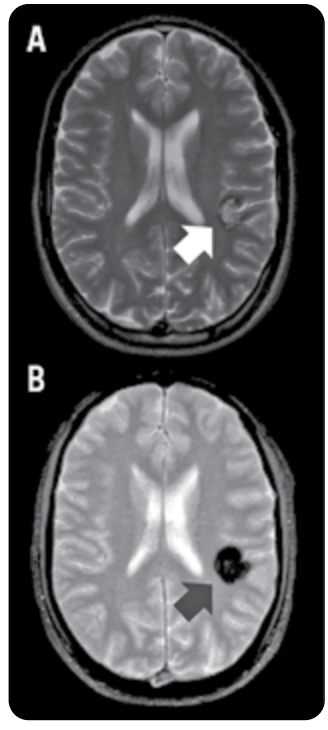

**Figure 21. MRI of cavernous malformation**
A. T2 weighted imaging MRI
B. Gradient echo sequencing MRI

**Clinical Course of Untreated Cerebral Cavernous Malformations (CCM)**
Lancet Neurol 2015 pii: S1474-4422(15)00303-8
**Summary**: (1) mode of clinical presentation and (2) CCM location are independently associated with ICH within 5 yr of CCM diagnosis. The risk of recurrent hemorrhage from a CCM is greater than the risk of first event and declines over 5 yr.
**Methods**: Collected individual patient data from investigators of published studies on MEDLINE and Embase since inception until April 2015 (7 cohorts from 6 studies, n=1620) on clinical course from CCM diagnosis until first CCM treatment or last available follow-up.
**Results**: 204 of 1620 experienced ICH during 5187 person-year follow-up (Kaplan-Meier estimated 5-year risk 15.8%, 95% CI 13.7-17.9). ICH within 5 yr of CCM was associated with clinical presentation with ICH or focal neurological deficit without brain imaging evidence of recent hemorrhage (vs. other presentations; HR 5.6, 95% CI 3.2-9.7) and with brainstem CCM location (vs. other locations; HR 4.4, 95% CI 2.3-8.6).

# Cerebrospinal Fluid Fistulas

### Etiology
- cranial or spinal
- traumatic: after head trauma, iatrogenic (post-transsphenoidal surgery, post skull base surgery)
- nontraumatic: high pressure (hydrocephalus, tumour), normal pressure (bone erosion secondary to infection, congenital defect)

### Clinical Features
- otorrhea or rhinorrhea (clear fluid)
- low pressure H/A (worse when sitting up)
- confirmatory testing for CSF: β transferrin test, quantitative glucose analysis of fluid, "ring sign", "reservoir sign"

### Investigations
- CT (detect pneumocephalus, fractures, skull base defects), water contrast CT cisternography

### Treatment
- lower ICP (avoid straining, acetazolamide to reduce CSF production, modest fluid restriction)
- persistent leak: may require continuous lumbar drainage via percutaneous catheter
- surgical indications: traumatic leak lasting >2 wk, spontaneous leaks, delayed onset of leak after trauma or surgery, leaks complicated by meningitis

Suspect CSF fistula in patients with otorrhea or rhinorrhea after head trauma or recurrent meningitis

**Ring Sign**: If CSF is stringed with blood. Allow CSF to drain onto the surrounding sheets; positive if clear in centre with surrounding blood coloured ring (double ring sign)
**Reservoir Sign**: Gush of CSF leaks out in certain head positions; i.e. teapot sign (not specific or sensitive)

**Stereotactic Radiosurgery for Cavernous Malformations (CM)**
J Neurosurg. 2010;113(4):691-9
**Summary**: SRS is a safe intervention for CMs, with advantages of reducing rebleed risks in patients with repeated pretreatment hemorrhage. Treating CMs with single bleed is less clear. However, the morbidity of repeated hemorrhage outweights any radiosurgery related morbidity and early active management of deep-seated CMs should be considered.
**Methods**: Retrospective analysis of 113 patients with 79 brainstem and 39 thalamic/basal ganglia CMs treated with gamma knife surgery.
**Results:**
1. Patients with multiple symptomatic hemorrhages before radiosurgery (n=41): rebleed rate decreased from 30.5% per lesion to 15% for the first 2 years after radiosurgery and 2.4% subsequently. Pretreatment multiple bleeds led to permanent deficits in 72% of these patients.
2. Patients with ≤1 symptomatic bleed before radiosurgery (n=77): natural history is uncertain due to short period between presenting bleed and treatment (median 1 year). Rate of hemorrhage was 5.1% for the first 2 years and 1.3% subsequently. Pretreatment hemorrhages led to permanent deficits in 43% of these patients (significantly lower than multiple-bleeds group, p<0.001).
3. Permanent adverse radiation effects were rare (7.3%) and minor in both groups.
4. Posttreatment hemorrhages led to persistent deficits in 7.3% of patients.

**RED FLAGS for Back Pain**
**BACK PAIN**
**B**owel/**B**ladder (retention or incontinence)
**A**nesthesia (saddle)
**C**onstitutional symptoms
"**K**"hronic disease
**P**arasthesia
**A**ge >50 yr or <20 yr
**I**V drug use
**N**euromotor deficits
**Cauda Equina**
- Urinary retention or incontinence, fecal incontinence or loss of anal sphincter tone, saddle anesthesia, uni/bilateral, leg weakness/pain

**Malignancy**
- Age >50 yr, previous Hx of cancer, pain unrelieved by bed rest, constitutional symptoms

**Infection**
- Increased ESR, IV drug use, immunosuppressed, fever

**Compression Fracture**
- Age >50 yr, trauma, prolonged steroid use

# EXTRACRANIAL PATHOLOGY

# Approach to Limb/Back Pain

- see Orthopedic Surgery, OR3

# Extradural Lesions

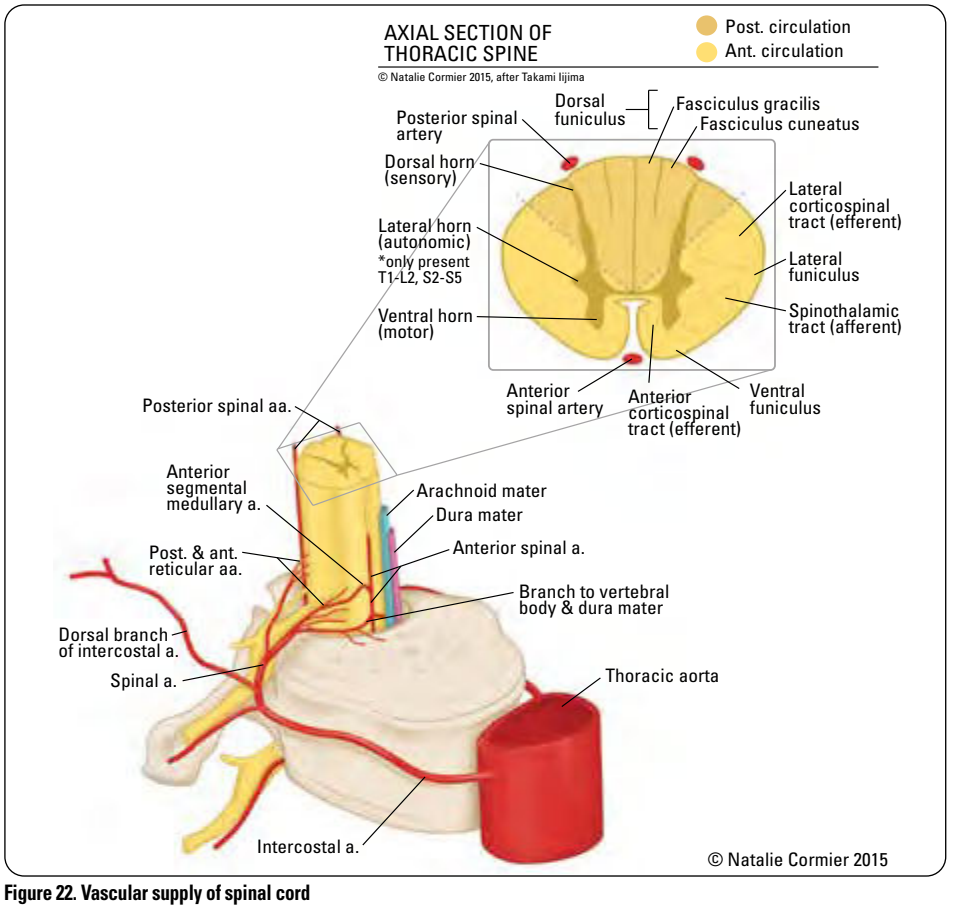

**Figure 22. Vascular supply of spinal cord**

# Root Compression

- radiculopathy is a pain and/or sensorimotor deficit syndrome that involves compression of a nerve root. Nerve compression generally occurs as a result of disc herniation, degenerative disc diseases (spondylosis), instability, and rarely, masses
- patients generally present with referred pain, sensory changes (numbness and/or tingling) or weakness. Whereas patients might sometime describe sensory changes in a dermatomal distribution, the referred pain will not be in a dermatomal distribution. The areas of pain and altered sensorium may be incongruent
- muscle innervation has less overlap than sensory innervation and hence is a better predictor of level of pathology

**Sensory Fibres**
Fasciculus gracilis/cuneatus: proprioception, fine touch, vibration
Spinothalamic tract: pain and temperature
**Motor Fibres**
Corticospinal tract: skilled movements

### Differential Diagnosis
- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

# Cervical Disc Syndrome

### Etiology
- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)

Disc herniations impinge the nerve root at the level **below** the interspace (i.e. C5-6 disc affects the C6 nerve root)

### Clinical Features
- pain in arm follows nerve root distribution, worse with neck extension, ipsilateral rotation, and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

### Investigations
- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG/nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue

### Treatment
- conservative
  - no bedrest unless severe radicular symptoms
  - activity modification, patient education (reduce sitting, lifting)
  - physiotherapy, exercise programs focus on strengthening core muscles
  - analgesics; NSAIDs are more efficacious
  - avoid cervical manipulation like traction
- surgical indications
  - anterior cervical discectomy is the usual approach (posterior formanotomy with discectomy is the other option)
  - intractable pain despite adequate conservative treatment for >3 mo
  - progressive neurological deficit

### Prognosis
- 95% improve spontaneously in 4-8 wk

**Table 14. Lateral Cervical Disc Syndromes**

| | C4-5 | C5-6 | C6-7 | C7-T1 |
|---|---|---|---|---|
| **Root Involved** | C5 | C6 | C7 | C8 |
| **Incidence** | 2% | 19% | 69% | 10% |
| **Sensory** | Shoulder | Thumb | Middle finger | Ring finger, 5th finger |
| **Motor** | Deltoid, biceps, supraspinatus | Biceps, wrist extensors | Triceps | Digital flexors, intrinsics |
| **Reflex** | No change | Biceps, brachioradialis | Triceps | Finger jerk (Hoffmann's sign) |

# Cervical Spondylosis

### Definition
- progressive degenerative process of cervical spine leading to canal stenosis – congenital spinal stenosis, degeneration of intervertebral discs, hypertrophy of lamina, dura, or ligaments, subluxation, altered mobility, telescoping of the spine due to loss of height of vertebral bodies, alteration of normal lordotic curvature
- resultant syndromes: mechanical neck pain, radiculopathy (root compression), myelopathy (spinal cord compression)

Cervical spondylotic myelopathy is the most common cause of spinal cord impairment

### Epidemiology
- typically begins at age 40-50, M>F, most commonly at the C5-C6 > C6-C7 levels

### Pathogenesis
- any of: disc degeneration/herniation, osteophyte formation, ossification, and hypertrophy of ligaments
- pathophysiology includes static compression, dynamic compression, and vascular compromise

### Clinical Features
- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling's test)
- the earliest symptoms are gait disturbance and lower extremity weakness or stiffness
- occipital H/A is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder, and arm pain, paresthesias, and numbness
- cervical spondylotic myelopathy may present with:
  - weakness (upper > lower extremity), lower extremity weakness (corticospinal tracts) is most worrisome complaint
  - decreased dexterity, loss of fine motor control
  - sensory changes
  - UMN findings such as hyperreflexia, clonus, and Babinski reflex
  - funicular pain, characterized by burning and stinging ± Lhermitte's sign (lightning-like sensation down the back with neck flexion)

**Clinical Grading Scores to Assess CSM**
- mJOA
- Nurick Grade
- Neck Disability Index

### Investigations
- x-ray of cervical spine ± flexion/extension (alignment, fractures)
- MRI most useful for determination of compression of the neural element
- CT is only used for better determination of bony anatomy (i.e. OPLL)
- EMG/nerve conduction studies reserved for peripheral nerve investigation

**A Clinical Practice Guideline for the Management of Patients with Degenerative Cervical Myelopathy (Dcm): Recommendations for Patients with Mild, Moderate, and Severe Disease and Nonmyelopathic Patients with Evidence of Cord Compression**
Global Spine Journal 2017; 7(3S):70S-83S
**Severe and moderate DCM**: Moderate evidence suggesting strong recommendation of surgical intervention.
**Mild DCM**: Very low to low evidence suggesting offering surgical intervention or a structured rehabilitation and if non-operative management initially pursued, consider operative intervention if evidence of neurological deterioration.
**Non-myelopathic patients without radiculopathy**: In such patients with imaging evidence of cervical cord compression, suggestion of not offering prophylactic surgery; counsel, educate, and follow clinically.
**Non-myelopathic patients with radiculopathy**: Such patients with imaging evidence of cervical cord compression are at a higher risk of developing myelopathy and should be counselled. Offer surgical or nonoperative treatment with appropriate follow-up and structured rehabilitation.

### Treatment
- nonsurgical: physiotherapy, anti-inflammatory medications
- surgical: anterior approach (anterior cervical discectomy or corpectomy), posterior approach (decompressive cervical laminectomy)
- in multilevel CSM, an anterior approach is associated with better postoperative neural function but has a higher complication and reoperation rate than the posterior group
- surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain
- complete remission almost never occurs; surgical decompression may stop progression of disease

# Lumbar Disc Syndrome

### Definition
- compression of nerve roots caused by herniation of the nucleus pulposus through the annulus fibrosus of an intervertebral disc in the lumbar spine

### Etiology
- posteriolaterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
- far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
- central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

### Clinical Features
- initially back pain, then leg pain > back pain
- limited back movement (especially forward flexion) due to pain
- motor weakness, dermatomal sensory changes, decreased reflexes
- exacerbation with valsalva; relief with flexing the knee or thigh
- nerve root tension signs
  - straight leg raise (Lasegue's test) or crossed SLR (pain should occur at less than 60°) suggests L5, S1 root involvement
  - femoral stretch test suggests L2, L3, or L4 root involvement

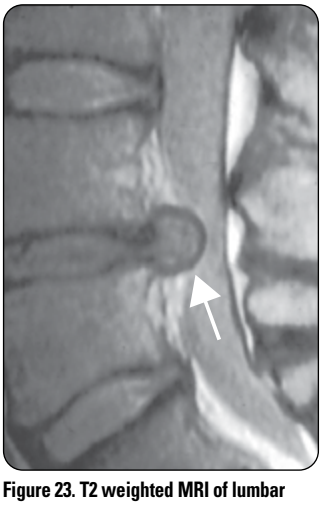

**Figure 23. T2 weighted MRI of lumbar disc herniation**

### Investigations
- MRI is modality of choice
- x-ray spine (only to rule out other lesions), CT (bony anatomy)
- myelogram and post-myelogram CT (only if MRI is contraindicated)

### Treatment
- conservative (same as cervical disc disease)
- surgical indications: same as cervical disc and cauda equina syndrome

### Prognosis
- 95% improve spontaneously within 4-8 wk
- those who do not improve with conservative treatment achieve symptom relief quicker with surgery than continuation of conservative management; however, the long-term outcome after surgery is comparable to conservative therapy
- do not follow patients with serial MRIs; clinical status is more important at guiding management

**Table 15. Lateral Lumbar Disc Syndromes**

| | L3-4 | L4-5 | L5-S1 |
|---|---|---|---|
| **Root Involved** | L4 | L5 | S1 |
| **Incidence** | <10% | 45% | 45% |
| **Pain** | Femoral pattern | Sciatic pattern | Sciatic pattern |
| **Sensory** | Medial leg | Dorsal foot to hallux<br>Lateral leg | Lateral foot |
| **Motor** | Tibialis anterior (dorsiflexion) | Extensor hallucis longus (hallux extension) | Gastrocnemius, soleus (plantar flexion) |
| **Reflex** | Patellar | Medial hamstrings | Achilles |

**Table 16. Differentiating Conus Medullaris Syndrome from Cauda Equina Syndrome**

| | Conus Medullaris Syndrome | Cauda Equina Syndrome |
|---|---|---|
| **Onset** | Sudden, bilateral | Gradual, unilateral |
| **Spontaneous Pain** | Rare, if present usually bilateral, symmetric in perineum or thighs | Severe, radicular type: in perineum, thighs, legs, back, or bladder |
| **Sensory Deficit** | Saddle; bilateral and symmetric; sensory dissociation | Saddle; no sensory dissociation; may be unilateral and asymmetric |
| **Motor Deficit** | Symmetric; paresis less marked; fasciculations may be present | Asymmetric; paresis more marked; atrophy may be present; fasciculations rare |
| **Reflexes** | Only ankle jerk absent (preserved knee jerk) | Knee and ankle jerk may be absent |
| **Autonomic Symptoms (bladder dysfunction, impotence, etc.)** | Urinary retention and atonic anal sphincter prominent early; impotence frequent | Sphincter dysfunction presents late; impotence less frequent |

# Cauda Equina Syndrome

### Etiology
- compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
- decreased space in the vertebral canal below L2
- common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumour

### Clinical Features
- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
  - weakness in multiple root distribution
  - reduced deep tendon reflexes (knee or ankle)
- autonomic
  - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
- sensory
  - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
  - bilateral sensory loss or pain: depends on the level affected
  - saddle area (S2-S5) anesthesia
  - sexual dysfunction (late finding)

### Investigations
- urgent MRI to confirm compression of S2-S3-S4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present; volumes controversial but anything over 250 cc in a healthy individual is cause for concerns

**Surgical versus Non-Operative Treatment for Lumbar Disc Herniation: Eight-Year Results for the Spine Patient Outcomes Research Trial (SPORT)**
Spine 2014; 39(1): 3-16
**Methods**: In the RCT arm of the study, 501 patients with imaging-confirmed lumbar disc herniation were randomized to open discectomy versus standard non-operative management.
**Results**: Surgery was superior in intent-to-treat analysis for sciatica severity (p=0.005), patient satisfaction (p=0.013), and self-rated improvement (p=0.013) at 8 year follow-up. Improvements in pain, physical function, and disability were only seen in an as-treated analysis due to significant non-adherence to treatment assignment.
**Conclusion**: Patients who are carefully selected for surgical intervention show greater symptom improvement compared to non-operative management.

**Magnetic Resonance Imaging in Follow-Up Assessment of Sciatica**
NEJM 2013;368:999-1007
**Background**: Follow-up MRI is a controversial method for monitoring sciatica in patients with known lumbar-disc herniation.
**Methods**: Participants (n=283) were recruited from a simultaneous, parallel, randomized study comparing surgery and conservative care for sciatica (the Sciatica Trial). MRI and clinical assessment were undertaken pre-treatment and 1 yr post-treatment randomization to visualize disc herniation and evaluate outcome.
**Results**: At 1 yr, disc herniation was visible in 35% with a favourable outcome (complete, or nearly complete symptom resolution) and in 33% with an unfavourable outcome (p=0.70). A favourable outcome was reported in 85% of patients with disc herniation and 83% without disc herniation (p=0.70).
**Conclusions**: Anatomical abnormalities visible on repeated MRI 1 yr after treatment for sciatica due to lumbar-disc herniation could not distinguish patients with resolution of their symptoms from patients still experiencing symptoms.

**Causes of Cauda Equina Syndrome**
- Lumbar disc herniation
- Spinal stenosis
- Spinal tumour
- Epidural abscess
- Hematoma
- Trauma

### Treatment
- surgical decompression (<48 h) to preserve bowel, bladder, and sexual function, and/or to prevent progression to paraplegia
- consult radiation oncology for urgent symptomatic management if palliative oncology patient

### Prognosis
- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

## Lumbar Spinal Stenosis

### Etiology
- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

### Clinical Features
- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

### Investigations
- MRI is the optimal investigation to confirm and localize the level of stenosis (unlike nerve root compression which can be localized with clinical exam)

### Treatment
- conservative: NSAIDs, analgesia, physical therapy
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in destabilization)

**Long-Term Outcomes of Lumbar Spinal Stenosis: Eight-Year Results of the Spine Patient Outcomes Research Trial (SPORT)**
Spine 2015; 40(2): 63–76
**Methods**: In the RCT arm of the study, 289 patients were randomized to decompressive laminectomy (n=138) or standard non-operative care (n=151).
**Results**: Intent-to-treat analyses showed no difference in pain, physical function, and disability outcome measures, because 52% randomized to non-operative management had undergone surgery at 8 years. As-treated analyses showed early benefits for surgery until 4 years, however effects in primary outcomes converged between years 5-8.
**Conclusion**: Decompressive laminectomy for symptomatic spinal stenosis may show diminishing symptomatic benefits beyond 4 years.

## Neurogenic Claudication

### Etiology
- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

### Clinical Features
- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- induced by variable degrees of exercise or standing
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

### Investigations
- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

### Treatment
- same as for lumbar spinal stenosis

**Key Features of Neurogenic vs. Vascular Claudication**
**Neurogenic Claudication**: dermatomal distribution with positional relief occurring over minutes
**Vascular Claudication**: sclerotomal distribution with relief occurring with rest over seconds

# Intradural Intramedullary Lesions

## Syringomyelia (Syrinx)

### Definition
- cystic cavitation of the spinal cord
- presentation is highly variable, usually progresses over months to years
- initially pain, weakness; later atrophy and loss of pain and temperature sensation

### Etiology
- 70% are associated with Chiari I malformation, 10% with basilar invagination
- post-traumatic
- tumour
- tethered cord

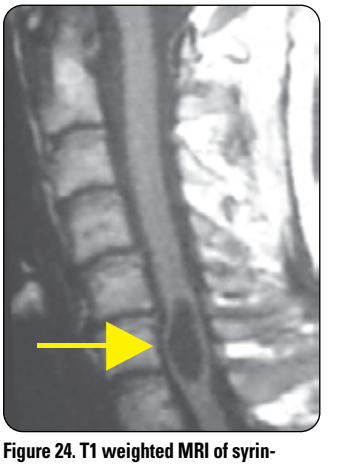

**Figure 24. T1 weighted MRI of syringomyelia**

### Clinical Features
- nonspecific features for any intramedullary spinal cord pathology:
  - initially pain, weakness, atrophy, then loss of pain and temperature (spinothalamic tract) in upper extremities (central syrinx) with progressive myelopathy over years
  - sensory loss with preserved touch and proprioception (dorsal column–medial lemniscus pathway) in a band-like distribution at the level of cervical syrinx
  - dysesthetic pain often occurs in the distribution of the sensory loss
  - LMN arm/hand weakness or wasting
  - painless neuropathic arthropathies (Charcot's joints), especially in the shoulder and neck due to loss of pain and temperature sensation

### Investigations
- MRI is best method, myelogram with delayed CT

### Treatment
- treat underlying cause (e.g. posterior fossa decompression for Chiari I, surgical removal of tumour if causing a syrinx)
- rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

**American Spinal Injury Association Impairment Scale**

| Grade | Description |
|---|---|
| A | Complete, no motor/sensory below neurological level including S4/5 |
| B | Incomplete, sensory but not motor function preserved below neurological level including S4/5 |
| C | Incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade <3 |
| D | Incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade ≥3 |
| E | Normal motor and sensory function |

# Spinal Cord Syndromes

### Complete Spinal Cord Lesion
- bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
- about 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

### Incomplete Spinal Cord Lesion
- any residual function at ≥4 segments below lesion
- signs include sensory/motor function in lower limbs and "sacral sparing" (perianal sensation, voluntary rectal sphincter contraction)

**Table 17. Comparison Between Incomplete Spinal Cord Lesion Syndromes**

| Syndrome | Etiology | Motor | Sensory |
|---|---|---|---|
| **Brown-Séquard** | Hemisection of cord | Ipsilateral LMN weakness at the lesion<br>Ipsilateral UMN weakness below the lesion | Ipsilateral loss of vibration and proprioception<br>Contralateral loss of pain and temperature<br>Preserved light touch |
| **Anterior Cord** | Anterior spinal artery compression or occlusion | Bilateral LMN weakness at the lesion<br>Bilateral UMN weakness below the lesion<br>Urinary retention | Preserved vibration and proprioception<br>Bilateral loss of pain and temperature<br>Preserved light touch |
| **Central Cord (most common)** | Syringomyelia, tumours, spinal hyperextention injury | Bilateral motor weakness: Upper limb weakness (LMN lesion) > Lower limb weakness (UMN lesion)<br>Urinary retention | Variable bilateral suspended sensory loss<br>Loss of pain and temperature > loss of vibration and proprioception |
| **Posterior Cord** | Posterior spinal artery infarction, trauma | Preserved | Bilateral loss of vibration, proprioception, light touch at and below the lesion<br>Preserved pain and temperature |

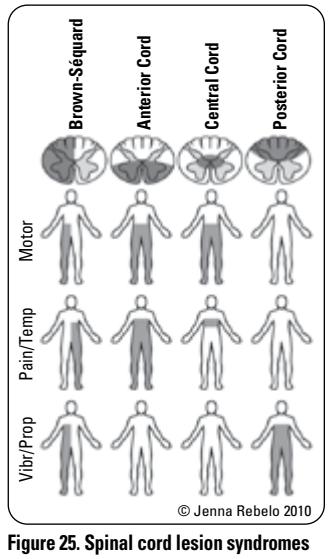

**Figure 25. Spinal cord lesion syndromes**

**Guideline for Timing of Decompressive Surgery in Management of Acute Spinal Cord Injury and Central Cord Syndrome: Results of a Systematic Review**
Global Spine Journal 2017; 7(3S): 195S-202S
**Summary of recommendations:**
- Low quality of evidence: Early surgery (<24 hours after injury) should be considered as a treatment option in adult patients with traumatic central cord syndrome.
- Low quality of evidence: Early surgery should be offered as an option for adult acute SCI patients, regardless of level of lesion.

# Peripheral Nerves

- see Neurology, N36

### Classification

**Table 18. Seddon's Classification of Peripheral Nerve Injury**

| Nerve Injury | Description | Recovery |
|---|---|---|
| **Neurapraxia (class I)** | Axon structurally intact but fails to function | Within hours to months (average 6-8 wk) |
| **Axonotmesis (class II)** | Axon and myelin sheath disrupted but endoneurium and supporting structures intact → Wallerian degeneration of axon segment distal to injury | Spontaneous axonal recovery at 1 mm/d, max at 1-2 yr |
| **Neurotmesis (class III)** | Nerve completely transected | Need surgical repair for possibility of recovery |

### Etiology
- ischemia
- nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve
- direct trauma (e.g. transection)
- iatrogenic

### Investigations
- clinical exam: muscle bulk and tone, power, sensation, reflexes, localization via Tinel's sign (paresthesias elicited by tapping along the course of a nerve)
- electrophysiological studies: EMG/nerve conduction study (assess nerve integrity and monitoring recovery after 2-3 wk post-injury)
- labs: blood work (e.g. CBC, TSH, Vitamin B12), CSF
- imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography, angiogram if vascular damage is suspected

### Treatment
- early neurosurgical consultation if injury is suspected

**Table 19. Treatment by Injury Type**

| Injury | Treatment |
|---|---|
| **Entrapment** | Conservative: Prevent repeated stress/injury, physiotherapy, NSAIDs, local anesthesia/steroid injection<br>Surgical: Nerve decompression ± transposition for progressive deficits, muscle weakness/atrophy, failure of medical management |
| **Stretch/Contusion** | Follow-up clinically for recovery; exploration if no recovery in 3 mo |
| **Axonotmesis** | If no evidence of recovery, resect damaged segment<br>Prompt physical therapy and rehabilitation to increase muscle function, maintain joint ROM, maximize return of useful function<br>Recovery usually incomplete |
| **Neurotmesis** | Surgical repair of nerve sheath unless known to be intact (suture nerve sheaths directly if ends approximate or nerve graft [usually sural nerve])<br>Clean laceration: early exploration and repair<br>Contamination or associated injuries: tag initially with nonabsorbable suture, reapproach within 10 d |

### Complications
- loss of function (temporarily or permanently)
- neuropathic pain: with neuroma formation
- complex regional pain syndrome: with sympathetic nervous system involvement

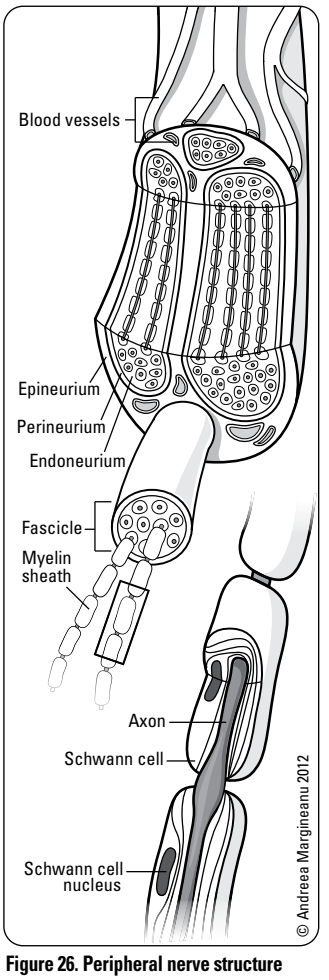

**Figure 26. Peripheral nerve structure**

# SPECIALTY TOPICS

# Neurotrauma

### Trauma Management (see Emergency Medicine, ER7)

### Indications for Intubation in Trauma
1. depressed or decreasing LOC (patient cannot protect airway): usually GCS ≤8
2. need for hyperventilation
3. severe maxillofacial trauma: patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management
   - if basal skull fracture suspected, avoid nasotracheal intubation as may inadvertently enter brain
   - note: intubation prevents patient's ability to verbalize for determining GCS

**Glasgow Coma Scale**

| Eye Response | Verbal Response | Motor Response |
|---|---|---|
| 4 spontaneous | 5 oriented | 6 obeys commands |
| 3 opens eyes to voice | 4 confused | 5 localizes to pain |
| 2 opens eyes to pain | 3 inappropriate words | 4 withdraws from pain |
| 1 no eye opening | 2 incomprehensible sounds | 3 flexion to pain (decorticate posturing) |
| | 1 no response | 2 extension to pain (decerebrate posturing) |
| | T intubated | 1 no response |

Best response for each component recorded individually (e.g. E3V3M5)
≥13 is mild injury; 9-12 is moderate injury; ≤8 is severe injury

# Trauma Assessment

### Initial Management

### ABCs of Trauma Management
- see Emergency Medicine, ER2

### NEUROLOGICAL ASSESSMENT

### Mini-History
- period of LOC, post-traumatic amnesia, loss of bowel/bladder control, loss of sensation, weakness, type of injury/accident
- in urgent situations, remember "**SAMPLE-F**": **s**igns/**s**ymptoms, **a**llergies, **m**edications, **p**ast medical history, **l**ast meal, **e**vents leading up to the trauma, and baseline **f**unctioning

### Neurological Exam
- ABCs
- vital signs
- GCS
- brainstem reflexes (if appropriate)
- cranial nerve exam
- motor and sensory exam, including peripheral reflexes
- spine (pain/tenderness, palpable deformity)
- sphincter tone and saddle sensation
- record and repeat neurological exam at regular intervals, as appropriate

### Investigations
- spinal injury precautions (cervical collar) are continued until C-spine is cleared
- C,T,L-spine x-rays
  - AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer's view if necessary) or CT
  - rarely done: oblique views looking for pars interarticularis fracture ("Scottie dog" sign)
- CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss of mastoid or sinus air spaces, blood in cisterns, pneumocephalus
- cross and type, ABG, CBC, drug screen (especially alcohol)
- chest and pelvic x-ray as indicated

### TREATMENT

### Treatment for Minor Head Injury (GCS 13-15)
- observation over 24-48 h
- wake every hour
- judicious use of sedatives or pain killers during monitoring period
- outpatient: advise patients to undergo stepwise approach to return to play and return to school (for latest recommendations, refer to Ontario Neurotrauma Foundation guidelines)

### Treatment for Moderate (GCS 9-12) and Severe Head Injury (GCS ≤8)
- clear airway and ensure breathing; intubate if necessary
- secure C-spine
- maintain adequate BP
- monitor for clinical deterioration
- monitor and manage increased ICP if present (see Herniation Syndromes, NS7)

### Admission required if:
- skull fracture (indirect signs of basal skull fracture, see Head Injury)
- confusion, impaired consciousness, concussion with >5 min amnesia
- focal neurological signs, extreme H/A, vomiting, seizures
- unstable spine
- use of alcohol
- poor social support

- Never do LP in head injury unless increased ICP has been ruled out
- All patients with head injury have C-spine injury until proven otherwise
- Suspect hematoma in alcoholic-related injuries
- Low BP after head injury means injury elsewhere
- Must clear spine both radiologically AND clinically

**Assessment of Spine CT/X-Ray (Parasagittal View)**
**ABCDS**
**A**lignment (columns: anterior vertebral line, posterior vertebral line, spinolaminar line, posterior spinous line)
**B**one (vertebral bodies, facets, spinous processes)
**C**artilage
**D**isc (disc space and interspinous space)
**S**oft tissues

**Comparative Effectiveness of Using Computed Tomography Alone to Exclude Cervical Spine Injuries in Obtunded or Intubated Patients: Meta-Analysis of 14,327 Patients with Blunt Trauma**
J Neurosurg 2011;115:541-549
**Purpose**: To determine the effectiveness of helical CT alone (vs. CT and adjuvant imaging such as MR) to diagnose acute unstable cervical spine injury following blunt trauma.
**Results**: 17 studies with 14,327 patients total. Sensitivity and specificity for modern CT were both >99.9% (95% CI 0.99 -1.00 for both). The negative predictive value of a normal CT scan was 100% (95% CI 0.96-1.00) and accuracy was not affected by the global severity of injury, CT slice thickness, or study quality.
**Conclusions**: CT alone is sufficient to detect unstable cervical spine injuries in trauma patients and adjuvant imaging is unnecessary with a negative CT scan result. Consequently, if a CT scan is negative for acute injury, the cervical collar may be removed from obtunded or intubated trauma patients.

## Head Injury

### Epidemiology
- M:F = 2-3:1

### Pathogenesis
- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/mesencephalic hematoma
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
  - low velocity: highest damage to structures on entry/exit path
  - high velocity: highest damage away from missile tract

### Scalp Injury
- rich blood supply
- considerable blood loss (vessels contract poorly when ruptured)
- minimal risk of infection due to rich vascularity

### Skull Fractures
- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
  - internal fractures into sinus may lead to meningitis, pneumocephalus
  - risk of operative bleed may limit treatment to antibiotics

**The Canadian CT Head Rule for Patients with Minor Head Injury**
Lancet 2001;357:1391-1396
**CT Head is only required for patients with minor head injuries with any one of the following:**
**High Risk** (for neurological intervention)
- GCS score <15 at 2 h after injury
- Suspected open or depressed skull fracture
- Any sign of basal skull fracture (hemotympanum, "raccoon" eyes, cerebrospinal fluid otorrhea/rhinorrhoea, Battle's sign)
- Vomiting ≥2 episodes
- Age ≥65 yr

**Medium Risk** (for brain injury on CT)
- Amnesia after impact >30 min.
- Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs).

**Minor Head Injury** is defined as witnessed LOC, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.

- basal skull fractures: not readily seen on x-ray, rely on clinical signs
  - retroauricular ecchymoses (Battle's sign)
  - periorbital ecchymoses (raccoon eyes)
  - hemotympanum
  - CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

### Cranial Nerve Injury
- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
  - CN II: local eye/orbit injury
  - CN III, IV, VI: if herniation secondary to mass
  - CN VIII: repair of ossicles
- CN injuries that improve
  - CN I: recovery may occur in a few months; most do not improve
  - CN III, IV, VI: majority recover
  - CN VII: recovery with delayed lesions
  - CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

### Arterial Injury
- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

### Intracranial Bleeding
- see *Blood*, NS6 and *Cerebrovascular Disease*, NS18

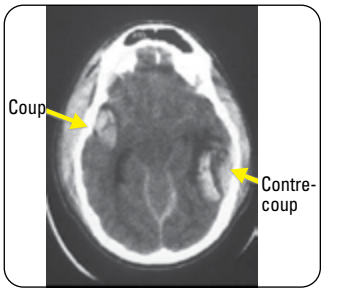

**Figure 27. CT showing coup-contrecoup injury**

## Brain Injury

### Primary Impact Injury
- mechanism of injury determines pathology: penetrating injuries, direct impact
  - low velocity: local damage
  - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
  - refer to American Academy of Neurology (AAN) guidelines for classification and management
  - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow) (Figure 27)
  - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
  - high density areas on CT ± mass effect
  - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
  - wide variety of damage results
  - may tear blood vessels (hemorrhagic foci)
  - often the cause of decreased LOC if no space-occupying lesion on CT

**AAN Classification**
Grade 1: altered mental status <15 min
Grade 2: altered mental status >15 min
Grade 3: any LOC

SIADH → hyponatremia
DI → hypernatremia

**Concussion Grades**

| AAN Grade | Management Options |
|---|---|
| 1 | Examine 15 min for amnesia and other symptoms<br>Return to normal activity if symptoms clear within 15 min |
| 2 | Remove from activity for 1 d, then re-examine<br>CT or MRI if H/A or other symptoms worsen or last >1 wk<br>Return to normal activity after 1 wk without symptoms |
| 3 | Emergent neurological exam and imaging; if initial exam is normal, may go home with close follow-up<br>Admit if any signs of pathology or persistent abnormal mental status<br><br>CT or MRI if H/A or other symptoms<br>If brief LOC (<1 min), return to normal activity after 1 wk without symptoms<br>If prolonged LOC (>1 min), return to normal activity only after 2 wk without symptoms |

### Secondary Pathologic Processes
- same subsequent biochemical pathways for each traumatic etiology
- delayed and progressive injury to the brain due to
  - high glutamate release → NMDA receptor activation → cytotoxic cascade
  - cerebral edema
  - intracranial hemorrhages
  - ischemia/infarction
  - raised ICP, intracranial HTN
  - hydrocephalus

### Extracranial Conditions
- hypoxemia
  - due to trauma to the chest, upper airway, brainstem
  - extremely damaging to vulnerable brain cells
  - leads to ischemia, raised ICP
- hypercarbia
  - leads to raised ICP (secondary to vasodilation)
  - systemic hypotension
  - caused by blood loss (e.g. ruptured spleen)
  - loss of cerebral autoregulation leads to decreased CPP, ischemia
- hyperpyrexia
  - leads to increased brain metabolic demands → ischemia

- fluid and electrolyte imbalance
  - iatrogenic (most common)
  - SIADH caused by head injury
  - DI
  - may lead to cerebral edema and raised ICP
- coagulopathy

### Intracranial Conditions
- raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

### Brain Injury Outcomes
- mildly traumatic (GCS 13-15): post-concussive symptoms: H/A, fatigue, dizziness, nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
- moderately traumatic (GCS 9-12): proportional to age (>40) and CT findings; 60% good recovery, 26% moderately disabled, 7% severely disabled, 7% vegetative/dead
- severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

### Late Complications of Head/Brain Injury
- seizures: 5% of head injury patients develop seizures
  - incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
  - post-traumatic seizure may be immediate, early, or late
  - presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
- meningitis: associated with CSF leak from nose or ear
- hydrocephalus: acute hydrocephalus or delayed NPH
- Post-Concussion Syndrome: H/A, dizziness, cognitive changes, psychological and behavioural symptoms

**A Trial of Intracranial-Pressure Monitoring in Traumatic Brain Injury**
NEJM 2012;367:2471-2481
**Background**: ICP monitoring is frequently used to monitor severe TBI, but controversy exists over whether it is beneficial.
**Methods**: Study sample (n=324 patients, ≥13 yr) consisted of those who had severe TBI and were being treated in ICU in Bolivia or Ecuador. Patients were randomly assigned to one management group:
1. ICP-monitoring based management.
2. Management based on imaging and clinical examination.
Primary outcome was a composite of survival time, impaired consciousness, functional status (at 3, 6 mo), and neuropsychological status (at 6 mo).
**Results**: No significant difference between management groups based on primary outcome, 6 mo mortality, median length of ICU stay, or occurrence of serious adverse events. However, duration of brain-specific treatments (e.g. use of hyperosmolar fluids or hyperventilation) higher in the imaging-clinical examination group (4.8 d vs. 3.4 d, p=0.002).
**Conclusion**: Maintaining monitored ICP at 20 mmHg or less is not superior to care based on imaging and clinical examination.

# Spinal Cord Injury

- see Orthopedic Surgery, OR23 and Emergency Medicine, ER9

### NEUROGENIC AND SPINAL SHOCK
1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by
   - interruption of sympathetics (unopposed parasympathetics) below the level of injury
   - loss of muscle tone due to skeletal muscle paralysis below level of injury → venous pooling (relative hypovolemia)
   - blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the SCI, causing flaccid paralysis and areflexia for variable periods

Resolution of spinal shock is indicated by the return of reflexes (most commonly the bulbocavernous reflex)

### Whiplash-Associated Disorders
- definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck

### Initial Management of Spinal Cord Injury
- major causes of death in SCI are aspiration and shock
- the following patients should be treated as having a SCI until proven otherwise:
  - all victims of significant trauma
  - minor trauma patients with decreased LOC or complaints of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

**Pharmacological Therapy for Acute Spinal Cord Injury: Congress of Neurological Surgeons (CNS) and American Association of Neurological Surgeons (AANS) Guidelines**
Neurosurgery 2013;72(Suppl 2):93-105
**Level I Recommendations**
- No Class I or Class II medical evidence supports the use of methylprednisone in the treatment of acute SCI. Several Class II and Class III studies have been published stating inconsistent effects of methylprednisone likely related to random chance or selection bias.
- Administration of GM-1 ganglioside (Sygen) for the treatment of acute SCI is not recommended.

### Stabilization and Initial Evaluation in the Hospital
1. ABCs, immobilization (backboard/head strap), oxygenation, Foley catheter to urometer, temperature regulation
2. hypotension: maintain sBP >90 mmHg with pressors (dopamine), hydration, and atropine
   - DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see Trauma Assessment, NS30)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
    - 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
    - flexion-extension views to disclose occult instability
    - CT scan (bony injuries) typically most trauma centres use CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners
    - MRI mandatory if neurological deficits (soft tissue injuries)

**Early vs. Delayed Decompression for Traumatic Cervical Spinal Cord Injury: Results of the Surgical Timing in Acute Spinal Cord Injury Study (STASCIS)**
PLoS ONE 2012;7:e32037. doi:10.1371/journal.pone.0032037
**Introduction**: This study sought to determine the relative effectiveness of early (<24 h after injury) versus late (≥24 h after injury) decompressive surgery following a traumatic cervical SCI.
**Methods/Population**: A prospective cohort study completed in 2002-2009 involving 6 North American institutions. Participants were 16-80 yr with a cervical SCI. Outcomes evaluated were changes in American Spinal Injury Association Impairment Scale (AIS) grade at 6 mo follow-up, complications, and mortality.
**Results**: Of 313 participants enrolled, 182 underwent early surgery and 131 underwent late surgery. 222 participants were available for follow-up at 6 mo. The odds of at least 2 grade AIS improvement were greater for those who had early surgery compared to those with late surgery (OR = 2.83, 95% CI 1.10, 7.28). Mortality was observed for each group during the first 30 d post injury. No statistically significant differences were observed for complications (p=0.21).
**Conclusion**: Early decompression surgery following a SCI is safe and associated with higher AIS improvement at 6 mo following injury.

### Medical Management Specific to Spinal Cord Injury
- option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
- ± decompression in acute, non-penetrating SCI

# Fractures of the Spine

## FRACTURES AND FRACTURE-DISLOCATIONS OF THE THORACIC AND LUMBAR SPINE
- assess ligamentous instability using flexion/extension x-ray views ± MRI
- thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
  - anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
  - middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
  - posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspinous, and ligamentum ligaments

### Types of Injury

**Table 20. Denis Classification of Spinal Trauma**

| Fracture Type | Description |
|---|---|
| **Compression Fracture (58%)** | Produced by flexion<br>Posterior ligament complex (supraspinous and interspinous ligaments, ligamentum flavum, and intervertebral joint capsules) remain intact<br>Fractures are stable but lead to kyphotic deformity |
| **Burst Fracture (17%)** | Stable: anterior and middle columns parted with bone retropulsed nearby<br>Hallmark is pedicle widening on AP x-ray<br>Spinal cord (seen on x-ray and CT); posterior column is uninjured<br>Unstable: same as the stable but with posterior column disruption (usually ligamentous) |
| **Flexion Distraction Injury (6%)** | Hyperflexion and distraction of posterior elements<br>Middle and posterior columns fail in distraction<br>Classic: Chance, horizontal fracture through posterior arch, pedicles, posterior vertebral body<br>Can be purely ligamentous, i.e. through PLL and disc |
| **Fracture-Dislocation (6%)** | Anterior and cranial dislocation of superior vertebral body → 3 column failure<br>Three types: (1) flexion-rotation, (2) flexion-distraction, (3) shear/hyperextension (rare) |

### Management of Thoracolumbar Injury
- severity and management based on thoracolumbar injury classification and severity (TLICS) classification

## FRACTURES OF THE CERVICAL SPINE

### Types of Injury

**Table 21. Fracture Patterns of the Cervical Spine**

| Fracture Type | Description |
|---|---|
| **C1 Vertebral Fracture** (Jefferson fracture) | Vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas), pushing the lateral masses of the atlas outward and disrupting the ring of the atlas<br>Also can cause an occipital condylar fracture |
| **Odontoid Fracture** | Causes C1 and odontoid of C2 to move independently of C2 body<br>This occurs because<br>Normally C1 vertebra and odontoid of C2 are a single functional unit<br>Alar and transverse ligaments on posterior aspect of odontoid usually remain intact after injury<br>Patients often report a feeling of instability and present holding their head with their hands<br>Type II fracture the most common |
| **C2 Vertebral Fracture** (hangman fracture) | Bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3 (spondylolisthesis of axis)<br>Usually neurologically intact |
| **Clay-Shoveler Fracture** | Avulsion of spinous process, usually C6 or C7 |

### Imaging
- AP spine x-ray (open-mouth and lateral view), CT

### Treatment
- immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
- Type II and III odontoid fractures
- consider surgical fixation for comminution, displacement, or inability to maintain alignment with external immobilization
- confirm stability after recovery with flexion-extension x-rays

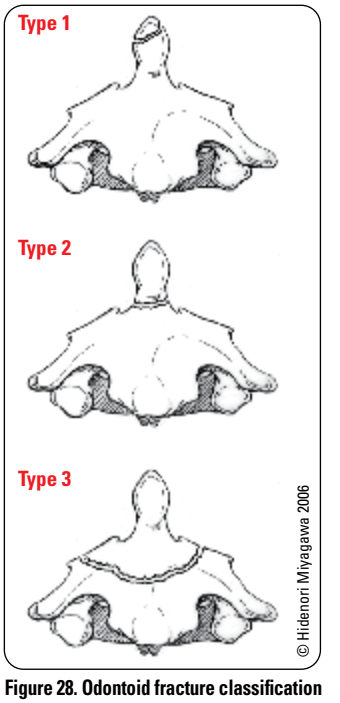

**Figure 28. Odontoid fracture classification**

# Neurologically Determined Death

### Definition
- irreversible and diffuse brain injury resulting in absence of clinical brain function
- cardiovascular activity may persist for up to 2 wk

### Criteria of Diagnosis
- prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/poisoning, temperature >32°C, no electrolyte/acid-base/endocrine disturbance
- absent brainstem reflexes: pupillary light reflex, corneal reflexes, oculocephalic response, caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides), pharyngeal and tracheal reflexes, cough with tracheal suctioning, absent respiratory drive at $PaCO_2$ ≥60 mmHg, ≥20 mmHg rise above baseline, and pH ≤7.28 (apnea test)
- 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
- confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

# Coma

### Definition
- an unrousable state in which patients show no meaningful response to environmental stimuli

### Pathophysiology
- lesions affecting the cerebral cortex bilaterally, the reticular activating system or their connecting fibres
- focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures

### Classification
- structural lesions (tumour, pus, blood, infarction, CSF): 1/3 of comas
  - supratentorial mass lesion: leads to herniation
  - infratentorial lesion: compression of or direct damage to the RAS or its projections
- metabolic disorders/diffuse hemispheric damage: 2/3 of comas
  - deficiency of essential substrates (e.g. oxygen, glucose, vitamin B12)
  - exogenous toxins (e.g. drugs, heavy metals, solvents)
  - endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
  - infections (meningitis, encephalitis)
  - trauma (concussion, diffuse shear axonal damage)

### Investigations and Management
- ABCs
- labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
- CT/MRI, LP (after ruling out space-occupying lesion/increased ICP), EEG

# Persistent Vegetative State

### Definition
- a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
- "awake but not aware"
- follows comatose state

### Etiology/Prognosis
- most commonly caused by cardiac arrest or head injury
- due to irreversible loss of cerebral cortical function but intact brainstem function
- average life expectancy is 2-5 yr

# Pediatric Neurosurgery

## Spinal Dysraphism

- spinal dysraphism refers to a spectrum of congenital anomalies resulting in a defective neural arch through which CNS elements are herniated
- the spectrum is divided largely into aperta (visible lesion; no skin covering) and occulta (no visible lesion; skin covering)

**Thoracolumbar Injury Classification and Severity Scoring**

| Parameter | Points |
|---|---|
| **Morphology** | |
| Compression fracture | 1 |
| Burst fracture | 2 |
| Translational/rotational fracture | 3 |
| Distraction | 4 |
| **Neurologic Status** | |
| Intact | 0 |
| Nerve root injury | 2 |
| **Spinal Cord Status** | |
| Incomplete | 3 |
| Complete | 2 |
| Cauda equine | 3 |
| **Posterior Ligamentous Complex** | |
| Intact | 0 |
| Injury suspected/indeterminate | 2 |
| Injured | 3 |

- TLICS scoring based on morphology of injury, status of posterior ligamentous complex, and neurological status
- Non-operative management if TLICS = 0-3, operative management if TLICS = 5+, either operative or non-operative if TLICS = 4

**Prenatal vs. Postnatal Repair of Myelomeningocele (MMC)**
NEJM 2011; 364:993-1004
**Methods**: RCT comparing prenatal surgery (before 26 weeks of gestation) and standard postoperative surgery. 12 mo outcomes included, death or need for placement of a CSF shunt. 30 mo outcomes included mental development and motor function.
**Results**: 40% of prenatal-surgery patients, compared to 82% of postnatal-surgery patients, required CSF shunt (P<0.001). Prenatal surgery resulted in improvement in mental development and motor function (P=0.007). However, prenatal surgery was associated with an increased risk of gynecological complications.
**Conclusion**: Prenatal surgery for MMC reduced need for shunting and improved motor outcomes but was associated with maternal and fetal risks related to preterm delivery.

**Table 22. Summary of Spinal Dysraphic Anomalies**

| | SPINA BIFIDA OCCULTA | MENINGOCELE (SPINA BIFIDA APERTA) | MYELOMENINGOCELE (SPINA BIFIDA APERTA) |
|---|---|---|---|
| **Definition** | Congenital absence of a spinous process and a variable amount of lamina<br>No visible exposure of meninges or neural tissue | Herniation of meningeal tissue and CSF through a defect in the spine, without associated herniation of neural tissue | Herniation of meningeal and CNS tissue through a defect in the spine |
| **Epidemiology** | 15-20% of the general population; most common at L5 or S1 | 0.1-0.2% of live births | 0.1-0.2% of live births |
| **Etiology** | | Failure of fusion of posterior neural arch | Primary failure of neural tube closure |
| **Clinical Features** | No obvious clinical signs<br>Presence of lumbosacral cutaneous abnormalities (dimple, sinus, port-wine stain, or hair tuft) should increase suspicion of an underlying anomaly (lipoma, dermoid, diastematomyelia) | Most common in lumbosacral area<br>Usually no disability, low incidence of associated anomalies, and hydrocephalus | Sensory and motor changes distal to anatomic level producing varying degrees of weakness<br>Urinary and fecal incontinence<br>Hydrocephalus (65-85% of patients)<br>Most have Type II Chiari malformation (see *Chiari Malformations*) |
| **Investigations** | Plain film: Absence of the spinous process and minor amounts of the neural arch<br>U/S, MRI to exclude spinal anomalies | Plain films, CT, MRI, U/S, echo, GU investigations | Plain films, CT, MRI, U/S, echo, GU investigations |
| **Treatment** | Requires no treatment | Surgical excision and tissue repair | Surgical closure to preserve neurologic status and prevent CNS infections<br>Closure *in utero* shown to decrease hydrocephalus and improve post natal motor scores |
| **Prognosis** | Generally good prognosis | Good prognosis with surgical treatment | Operative mortality close to 0%, 95% 2-yr survival<br>80% have IQ >80 (but most are 80-95), 40-85% ambulatory, 3-10% have normal urinary continence<br>Early mortality: usually due to Chiari malformation complications (respiratory arrest, aspiration), late mortality: due to shunt malfunction |

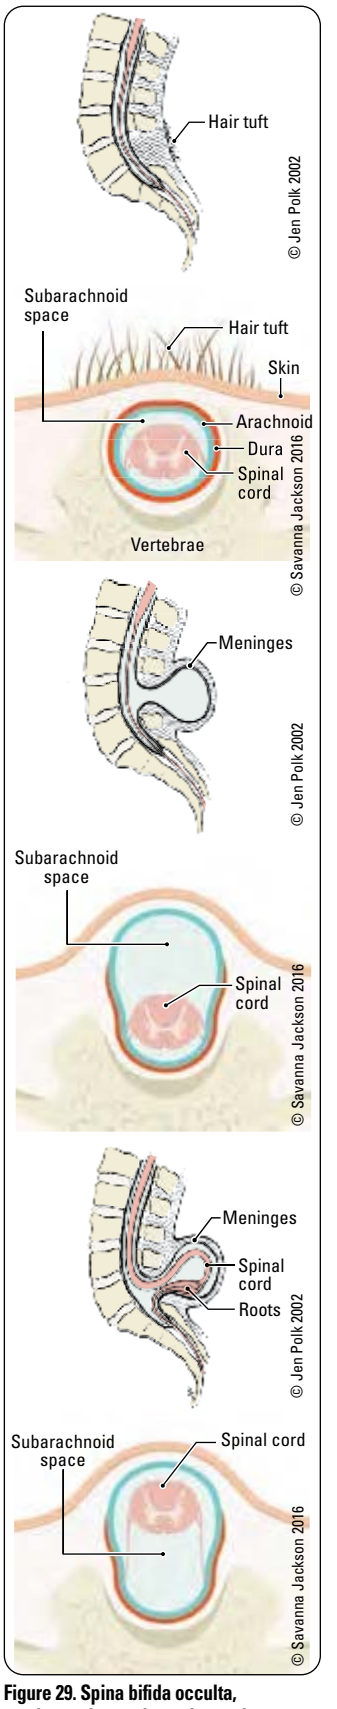

**Figure 29. Spina bifida occulta, meningocele, myelomeningocele**

# Intraventricular Hemorrhage

## Definition
- hemorrhage originating in the periventricular subependymal germinal matrix

## Epidemiology
- incidence and severity increases as GA and BW decrease
- 50% of IVH occurs within 8 h of birth; 90% occurs by day 3

## Risk Factors
- prematurity (<32 wk), BW <1500 g, need for vigorous resuscitation at birth, pneumothorax, ventilated preterm infants, hemodynamic instability, RDS, chorioamnionitis, coagulopathy

## Clinical Feature
- many infants with IVH are asymptomatic
- subtle signs: altered LOC, decreased tone and/or activity, hypoventilation/apnea
- catastrophic deterioration: may have bulging fontanelle, apnea/hypoventilation, hypotension, bradycardia, cranial nerve abnormalities, sudden drop in hematocrit, metabolic acidosis, seizures, coma

## Diagnosis
- head U/S is preferred imaging modality
- routine head U/S screening conducted for all preterm infants <32 wk or <1500 g gestation throughout NICU stay
- IVH graded using Papile classification
- parenchymal hemorrhage may also occur in the absence of IVH

## Management of Acute Hemorrhage
- supportive care to maintain blood volume, cerebral perfusion, and acid-base status
- follow-up with serial imaging

### Prognosis
- outcome largely dependent on grade of IVH, with grades I and II having a relatively favourable prognosis
- greatest morbidity and mortality is seen with grade IV IVH and development of posthemorrhagic hydrocephalus requiring ventriculoperitoneal shunt placement
- short-term sequelae for severe IVH: mortality, extension of bleed, posthemorrhagic hydrocephalus, posthemorrhagic infarction, cyst formation
- possible long-term major neurological sequelae: CP, cognitive deficits, motor deficits, visual and hearing impairment

**Papile Classification**
Grade I: germinal matrix hemorrhage
Grade II: IVH without ventricular dilatation
Grade III: IVH with ventricular dilatation
Grade IV: IVH with parenchymal extension

## Hydrocephalus in Pediatrics

### Etiology
- congenital
  - aqueductal anomalies, primary aqueductal stenosis in infancy
  - secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
  - Dandy-Walker malformation (2-4%)
  - Chiari malformation, especially Type II
  - myelomeningocele
- acquired
  - post meningitis
  - post hemorrhage (SAH, IVH)
  - masses (vascular malformation, neoplastic)

### Clinical Features
- symptoms and signs of hydrocephalus are age related in pediatrics
- increased head circumference, bulging anterior fontanelle, widened cranial sutures
- irritability, lethargy, poor feeding, and vomiting
- "cracked pot" sound on cranial percussion
- scalp vein dilation (increased collateral venous drainage)
- sunset sign (forced downward deviation of eyes)
- episodic bradycardia and apnea

### Investigations
- skull x-ray, U/S, CT, MRI, ICP monitoring

### Treatment
- similar to adults (see *Hydrocephalus Treatment*, NS9)

## Dandy-Walker Malformation

### Definition
- atresia of foramina of Magendie and Luschka, resulting in:
  - complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic cerebellar hemispheres
  - posterior fossa cyst, enlarged posterior fossa
  - dilatation of 4th ventricle (also 3rd and lateral ventricles)
  - can be detected *in utero*
- associated anomalies
  - hydrocephalus (90%)
  - agenesis of corpus callosum (17%)
  - occipital encephalocele (7%)

### Epidemiology
- 2-4% of pediatric hydrocephalus

### Clinical Features
- 20% are asymptomatic, seizures occur in 15%
- symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
- ataxia, spasticity, poor fine motor control common in childhood

### Investigations
- ultrasound, CT, MRI

### Treatment
- asymptomatic patients require no treatment
- associated hydrocephalus requires surgical treatment
  - e.g. ventriculoperitoneal shunt, cystoperitoneal shunt, lumboperitoneal shunt, ventriculoatrial shunt, lumbar drain

### Prognosis
- 75-100% survival, 50% have normal IQ

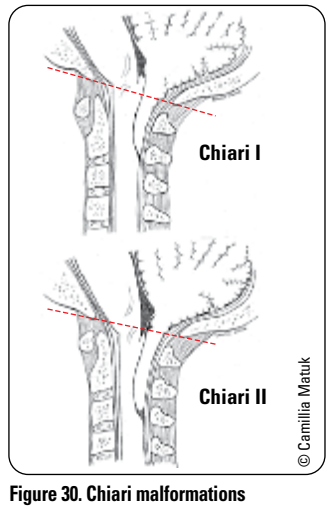

**Figure 30. Chiari malformations**

# Chiari Malformations

## Definition
- malformations at the medullary-spinal junction

## Etiology
- unclear, likely maldevelopment/dysgenesis during fetal life

## Categories

**Table 23. Categories of Chiari Malformations**

| | Type I | Type II |
|---|---|---|
| **Definition** | Cerebellar tonsils lie below the level of the foramen magnum | Part of cerebellar vermis, medulla, and 4th ventricle extend through the foramen magnum often to midcervical region |
| **Epidemiology** | Average age at presentation 15 yr | Present in infancy |
| **Clinical Features** | Many are aysmptomatic<br>Pain (69%), weakness (56%), numbness (52%), loss of temperature sensation (40%)<br>Central cord syndrome (65%)<br>Foramen magnum compression syndrome (22%), Cerebellar syndrome (11%), Syringomyelia (50%), Hydrocephalus (10%) | Findings due to brainstem and lower cranial nerve dysfunction<br>Neurogenic dysphagia (69%), apnea (58%), stridor (56%), aspiration (40%), arm weakness (27%), downbeat nystagmus<br>Respiratory arrest is the most common cause of mortality<br>Usually associated with myelomingocele and hydrocephalus |
| **Investigations** | MRI | MRI |
| **Treatment** | Symptomatic patients (early surgery recommended; <2 yr post symptom onset) → suboccipital craniectomy, duraplasty | Preserved<br>When symptomatic, check the shunt first. Then consider surgical decompression (which does not reverse intrinsic brainstem abnormalities) → cervical laminectomy, duraplasty |

# Craniosynostosis

## Definition
- premature closure of the cranial suture(s)

## Classification
- sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
- coronal: expansion in superior and lateral direction (brachiocephaly)
- metopic (trigonocephaly)
- lambdoid: least common

## Epidemiology
- 0.6/1000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

## Clinical Features
- skull deformity, raised ICP ± hydrocephalus
- ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
- must differentiate from positional plagiocephaly (secondary to persistently/exclusively sleeping on back)

## Investigations
- plain radiographs, CT scan

## Treatment
- parental counselling about nature of deformity, associated neurological symptoms
- surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)

# Pediatric Brain Tumours

- see *Tumours*, NS11

**Most Common Pediatric Brain Tumours**
Astrocytoma, low grade
Supratentorial
Infratentorial
Medulloblastoma
Ependymoma
Glioblastoma

## Epidemiology
- 20% of all pediatric cancers (second only to leukemia)
- 60% of pediatric brain tumours are infratentorial
- pediatric brain tumours arise from various cellular lineages
- glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma multiforme (largely supratentorial) (see *Astrocytoma*, NS13)
- primitive nerve cells: supratentorial PNET
- 90% of neonatal brain tumours, infratentorial (medulloblastoma), pineal gland (pineoblastoma)
- non-neuronal cells: germ cell tumour, craniopharyngioma, dermoid, meningioma, neurinoma (schwanoma), pituitary adenoma, others

## Clinical Features
- vomiting, seizure, macrocrania, hydrocephalus
- developmental delay, poor feeding, failure to thrive
- often initially escapes diagnosis due to expansile cranium and neural plasticity in children

**Table 24. Overview of Childhood Primary Brain Tumours***

| | |
|---|---|
| **Pilocytic (low grade) Astrocytoma** | Usually in posterior fossa<br>Well circumscribed<br>Benign, good prognosis |
| **Medulloblastoma** | PNET<br>In cerebellum → compresses 4th ventricle → hydrocephalus<br>Highly malignant |
| **Ependymoma** | In 4th ventricle → hydrocephalus<br>Poor prognosis |
| **Hemangioblastoma** | Often cerebellar<br>Associated with von Hippel-Lindau syndrome with retinal angiomas<br>Can produce EPO → secondary polycythemia |
| **Craniopharyngioma** | Causes bitemporal hemianopsia (thus often confused with pituitary adenoma)<br>Most common supratentorial childhood tumour<br>Benign |

* See also, *Familial Cancer Syndromes*, Medical Genetics, MG7

# Functional Neurosurgery

## Movement Disorders

- see Neurology, *Parkinson's Disease*, N32, *Dystonia*, N33, and *Multiple Sclerosis*, N52

**Table 25. Surgical Targets for Movement Disorders**

| Disorder | Indications | Procedures | Outcomes | Morbidity |
|---|---|---|---|---|
| **Parkinson's Disease** | Intractable contralateral bradykinesia/tremor<br>Failure of medical management (advanced disease)<br>Drug-induced dyskinesias (see dystonia, below) | Simultaneous, bilateral surgery/stimulation is most common<br>Preferred target: Anterodorsal subthalamic nucleus<br>Other targets: stereotactic ablation (pallidotomy) or stimulation of posteroventral GPi<br>Caudal zona incerta<br>Parkinsonian tremor: stereotactic ablation (thalamotomy) or stimulation of ventral intermediate nucleus of thalamus | 39-48% improvement in Unified Parkinson's Disease Rating Scale (UPDRS) scores<br>Reduced dosage of medications (STN)<br>More effective than medical management in advanced PD<br>Early intervention may reduce severity, course, and progression of disease<br>Less effective for patients with atypical presentations | IH, infection, seizure (1%-4%)<br>Paresthesias<br>Involuntary movements<br>Cognitive functioning: Decreased lexical fluency, impaired executive function (STN > GPi)<br>Psychiatric: Depression, mania, anxiety, apathy (STN > GPi) |
| **Dystonia** | Contralateral primary (generalized) dystonias; cervical and tardive dystonias<br>Contralateral secondary dyskinesia (i.e. drug-induced: L-dopa, neuroleptics) | Preferred target (primary dystonia): Stereotactic ablation (pallidotomy) or stimulation of posteroventral GPi<br>Secondary dystonia: stimulation of anterodorsal STN<br>Stimulation of ventral posterior lateral (VPL) thalamic nucleus | Primary dystonia: 51% reduction in Burke-Fahn-Marsden Dystonia Scale (BFMDS) score<br>Secondary dystonia: 62-89% improvement in dystonias<br>Delayed effects: Weeks to months | ICH, infection, seizure (1%-4%)<br>Minor effects on cognitive functioning (especially decreased lexical fluency; STN > GPi) |
| **Tremor** | Contralateral appendicular ET (first disorder to be treated by DBS; DBS is viable alternative to Rx)<br>Intention tremor resulting from demyelination of cerebellar outflow tracts (e.g. in multiple sclerosis)<br>Brainstem tremor (Holmes tremor) | Preferred target: Stereotactic ablation (thalamotomy) or stimulation of Vim nucleus of thalamus<br>Other targets: stimulation of caudal zona incerta<br>Parkinsonian tremor: stimulation of anterodorsal STN | Durable reductions in essential tremor rating scale (ETRS) scores<br>Reduced dosage of medications<br>Conflicting data on vocal/facial tremor | ICH, infection, seizure (1%-4%)<br>Paresthesias/pain<br>Dysarthria<br>Ataxia<br>Minor effects on cognitive functioning (especially decreased lexical fluency)<br>Tolerance may develop over time |

# Neuropsychiatric Disorders

- see Neurology, N20 and *Obsessive Compulsive Disorder* PS19 and *Depression*, PS12
- psychiatric neurosurgery indicated only for severe symptoms that are refractory to medical management

**Table 26. Surgical Targets for Neuropsychiatric Disorders**

| Disorder | Procedures | Outcomes | Morbidity |
|---|---|---|---|
| **Obsessive Compulsive Disorder (OCD)** | Anterior capsulotomy/stimulation of the anterior limb of the internal capsule (IC) | Currently under investigation<br>Reportedly 25-75% response rate | ICH (1-2%)<br>Mild effects on cognitive functioning<br>Anxiety ± panic disorder (case report) |
| **Tourette's Syndrome** | Stimulation of midline intralaminar nuclei of the thalamus<br>Stimulation of motor and limbic portions of GPi<br>Stimulation of the anterior limb of the IC | Currently under investigation<br>Reportedly >70% reduction in vocal or motor tics and urge | Intracerebral hemorrhages (1-2%)<br>Mild sexual dysfunction |
| **Major Depressive Disorder (MDD)** | Stimulation of the subgenual cingulate cortex<br>Anterior capsulotomy or stimulation of the anterior limb of the internal capsule (IC) | Currently under investigation<br>Reportedly 60% response rate; 35% remission rate | ICH (1-2%)<br>Pain, H/A<br>Worsening mood, irritability |

**Consensus on Guidelines for Stereotactic Neurosurgery for Psychiatric Disorders**
Journal of Neurology, Neurosurgery & Psychiatry 2014;85(9): 1003-1008

- Stereotactic ablative procedures such as cingulotomy and capsulotomy for MDD and OCD lack level I evidence.
- Deep brain stimulation in any brain target attempted so far is considered "investigational."
- Multidisciplinary teams are mandatory to ensure safe and ethical conduct in psychiatric neurosurgery, with particular attention directed to ensuring treatment refractoriness, consent procedures, patient capacity and autonomy, and extensive pre-/post- operative assessments.

- other experimental indications include: anorexia nervosa, substance use disorders, Tourette's syndrome, and functional neurological disorders, amongst others

# Chronic Pain

**Table 27. Surgical Targets for Chronic Pain**

| Disorder | Indications | Procedures | Outcomes | Morbidity |
|---|---|---|---|---|
| **Neuropathic Pain** | Severe, intractable, organic neuropathic pain (e.g. post-stroke pain, phantom limb pain, trigeminal neuralgia, chronic low-back pain, post-operative neuropathic pain, complex regional pain syndrome) | Preferred target: stimulation of the contralateral VPL<br>VPM thalamic nuclei ± periventricular/periaqueductal grey matter (PVG/PAG)<br>Other targets: stimulation of the contralateral IC<br>Stimulation of the contralateral motor cortex<br><br>For post-operative neuropathic pain, surgical procedure may be aimed at correcting any identifiable residual deformity from prior spine surgery<br>Surgery is not primary modality if no structurally correctable radiologic findings | 47% improvement in perception of pain intensity<br>Less favourable results in central pain syndromes and poorly localized pain | Intracerebral hemorrhages (1-2%)<br>Paresthesia<br>Anxiety ± panic disorder |
| **Nociceptive Pain** | Severe, intractable, organic nociceptive pain | Bilateral (most common) stimulation of the PVG/PAG | Reportedly 63% improvement in perception of pain intensity | Intracerebral hemorrhages (1-2%)<br>Paresthesia<br>Anxiety ± panic disorder |

# Surgical Management of Epilepsy

- see Neurology, N18 for the medical treatment of epilepsy

## Indications

- medically refractory seizures, usually defined as recurrent seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing; other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

### Procedure
- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common
- vagus nerve stimulation
- deep brain stimulation

### Outcomes
- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

### Morbidity
- 0.4-4% of surgical patients will have partial hemianopsia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
- most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
- the degree of memory decline stabilizes after 1-2 yr

### Predictors
- positive predictive factors for seizure freedom following anteromedial temporal lobectomy include:
  - hippocampal sclerosis (unilateral)
  - focal localization of interictal epileptiform discharges
  - absence of pre-operative generalized seizures
  - tumoural etiology
  - complete resection of the lesion
- ongoing research on neuroimaging biomarkers to predict treatment response, especially to neuromodulation

## Surgical Management for Trigeminal Neuralgia

- reserved for cases refractory to medical management; see Neurology, N42 for medical management

### Surgical Options
- trigeminal nerve branch procedures
  - local blocks (phenol, alcohol)
  - neurectomy of the trigeminal branch
  - nerve branches
  - V1 block at the supraorbital, supratrochlear nerves
  - V2 block at the foramen rotundum or infraorbital nerves
  - V3 block at the foramen ovale
- percutaneous trigeminal rhizotomy
  - glycerol injection
  - mechanotrauma via catheter balloon
- radiofrequency thermocoagulation
- Gamma Knife® radiosurgery
- microvascular decompression
  - posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable Teflon® felt

# Acronyms

| | |
|---|---|
| AC | abdominal circumference |
| ACOG | American College of Obstetricians and Gynecologists |
| AFI | amniotic fluid index |
| AFLP | acute fatty liver of pregnancy |
| AFV | amniotic fluid volume |
| AP | anteroposterior |
| APGAR | Appearance, pulse, grimace, activity, and respiration |
| aPTT | activated partial thromboplastin time |
| APS | antiphospholipid antibody syndrome |
| ARDS | acute respiratory distress syndrome |
| β-hCG | beta human chorionic gonadotropin |
| BPP | biophysical profile |
| C/S | Cesarean section |
| CHF | congestive heart failure |
| CMV | cytomegalovirus |
| CPD | cephalopelvic disproportion |
| CT | computed tomography scan |
| CTG | cardiotocography |
| CVS | chorionic villus sampling |
| CXR | chest X-ray |
| D&C | dilatation and curettage |
| DIC | disseminated intravascular coagulation |
| DM | diabetes mellitus |
| DVT | deep vein thrombosis |
| ECV | external cephalic version |
| EDD | estimated date of delivery |
| EFM | electronic fetal monitoring |
| eFTS | enhanced first trimester screen |
| EFW | estimated fetal weight |
| FDP | fibrin degradation products |
| FHR | fetal heart rate |
| FISH | fluorescence in situ hybridization |
| FL | femur length |
| FM | fetal movement |
| FPG | fasting plasma glucose |
| FTS | first trimester screen |
| GA | gestational age |
| GBS | Group B *Streptococcus* |
| GDM | gestational diabetes mellitus |
| GTN | gestational trophoblastic neoplasia |
| HC | head circumference |
| HELLP | hemolysis, elevated liver enzymes, low platelets |
| IMM | intramyometrial |
| IOL | induction of labour |
| IPS | integrated prenatal screen |
| ITP | idiopathic thrombocytopenic purpura |
| IUFD | intrauterine fetal death |
| IUGR | intrauterine growth restriction |
| IVH | intraventricular hemorrhage |
| L/S | lecithin-sphingomyelin ratio |
| LFT | liver function test |
| LLDP | left lateral decubitus position |
| LMP | last menstrual period |
| LMWH | low molecular weight heparin |
| MSAFP | maternal serum α-fetoprotein |
| MSS | maternal serum screening |
| MTX | methotrexate |
| N/V | nausea/vomiting |
| NIPT | non-invasive prenatal testing |
| NPO | nothing by mouth |
| NST | non-stress test |
| NTD | neural tube defects |
| NTUS | nuchal translucency ultrasound |
| OA | occiput anterior |
| OGCT | oral glucose challenge test |
| OGTT | oral glucose tolerance test |
| ONTD | open neural tube defect |
| OP | occiput posterior |
| OT | occiput transverse |
| PAPP-A | pregnancy-associated plasma protein A |
| PCR | polymerase chain reaction |
| PE | pulmonary embolism |
| PG | plasma glucose |
| PPD | postpartum depression |
| PPH | postpartum hemorrhage |
| PPROM | preterm premature rupture of membranes |
| PROM | premature rupture of membranes |
| PTL | preterm labour |
| QF-PCR | quantitative fluorescence-polymerase chain reaction |
| RDS | respiratory distress syndrome |
| RhIG | Rh immune globulin |
| ROM | rupture of membranes |
| SFH | symphysis fundal height |
| SOGC | Society of Obstetricians and Gynaecologists of Canada |
| SVD | spontaneous vaginal delivery |
| TENS | transcutaneous electrical nerve stimulation |
| TOLAC | trial of labour after Cesarean section |
| T1 | first trimester |
| T2 | second trimester |
| T3 | third trimester |
| TB | tuberculosis |
| TPN | total parenteral nutrition |
| TTP | thrombotic thrombocytopenic purpura |
| U/S | ultrasound |
| UTI | urinary tract infection |
| V/Q | ventilation/perfusion lung scan |
| VBAC | vaginal birth after Cesarean |
| vWD | von Willebrand disease |
| VTE | venous thromboembolism |

# Basic Anatomy Review

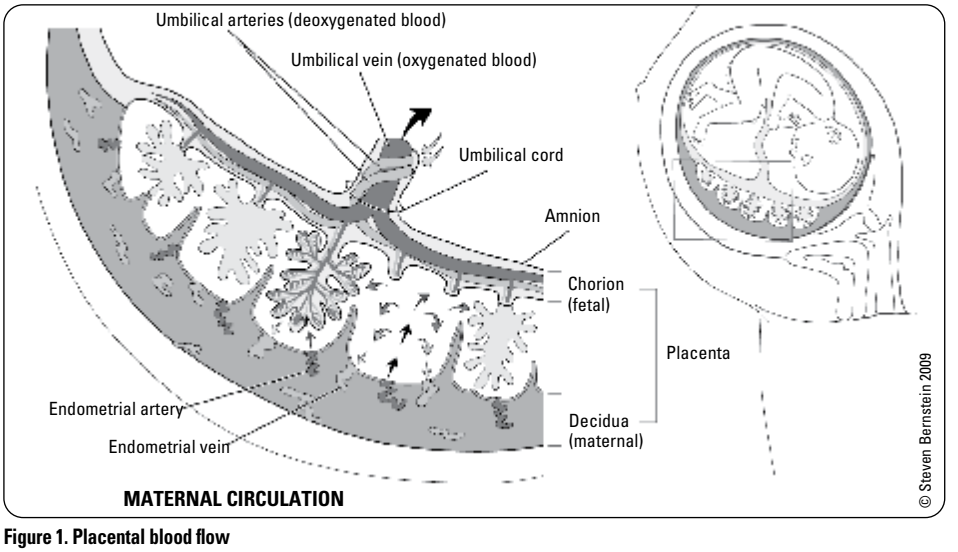

**Figure 1. Placental blood flow**

### Placenta

- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG, and infant growth factors
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see *Obstetrical Hemorrhage*, OB13)

# Pregnancy

## Diagnosis of Pregnancy

### History

- symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, and fatigue
- obstetrical and gynecological history: year, location, mode of delivery, duration of labour, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format
  - Gravidity (G)
    - **G**: total number of pregnancies of any gestation (multiple gestation=one pregnancy)
    - includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles

- Parity (TPAL)
  - **T**: number of term deliveries (>37 wk)
  - **P**: number of premature deliveries (20-36+6 wk)
  - **A**: number of abortions (ending <20 wk)
    - induced (therapeutic) and spontaneous (miscarriage)
  - **L**: number of living children

### Physical Signs
- uterine enlargement
- breast engorgement, areola darkening, and prominent vascular patterns
- Goodell's sign: softening of the cervix (4-6 wk)
- Chadwick's sign: bluish discolouration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)
- Hegar's sign: softening of the cervical isthmus (6-8 wk)

### Investigations
- β-hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
  - positive in serum 9 d post-conception, positive in urine 28 d after 1st day of LMP
  - plasma levels usually double every 1.4-2.0 d, peak at 8-12 wk, then fall, but continue to be measurable until delivery
- levels less than expected suggest ectopic pregnancy, abortion, inaccurate dates, or some normal pregnancies
- levels greater than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates
- U/S:
  - transvaginal
    - 5 wk GA: gestational sac visible
    - 6 wk GA: fetal pole visible
    - 7-8 wk GA: fetal heart activity visible
  - transabdominal
    - 6-8 wk GA: intrauterine pregnancy visible

**β-hCG Rule of 10s**
10 IU at time of missed menses
100,000 IU at 10 wk (peak)
10,000 IU at term

**Trimesters**
- T1 (first trimester): 1-14 wk
- T2 (second trimester): 14-28 wk
- T3 (third trimester): 28-42 wk
- Normal pregnancy term: 37-42 wk

# Maternal Physiologic Adaptations to Pregnancy

**Table 1. Physiologic Changes During Pregnancy**

| | |
|---|---|
| **Skin** | Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation), spider angiomas, palmar erythema due to increased estrogen, and striae gravidarum due to connective tissue changes |
| **Cardiovascular** | Hyper-dynamic circulation<br>Increased cardiac output, heart rate, and blood volume<br>Decreased blood pressure: decreased PVR and decreased venous return from enlarging uterus compressing IVC and pelvic veins<br>Increased venous pressure leads to risk of varicose veins, hemorrhoids, and leg edema |
| **Hematologic** | Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit<br>Increased leukocyte count but impaired function leads to improvement in some autoimmune diseases<br>Gestational thrombocytopenia: mild (platelets >70,000/μL) and asymptomatic, normalizes within 2-12 wk following delivery<br>Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery |
| **Respiratory** | Increased incidence of nasal congestion<br>Increased $O_2$ consumption to meet increased metabolic requirements<br>Elevated diaphragm (i.e. appears more "barrel-chested")<br>Increased minute ventilation leads to decreased $CO_2$ resulting in mild respiratory alkalosis that helps $CO^2$ diffuse across the placenta from fetal to maternal circulation<br>Decreased total lung capacity (TLC), functional residual capacity (FRC), and residual volume (RV)<br>No change in vital capacity (VC) and $FEV_1$ |
| **Gastrointestinal** | GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying)<br>Increased incidence of gallstones due to progesterone causing increased gallbladder stasis<br>Constipation due to progesterone causing decreased GI motility and hemorrhoids as a result of constipation and increased intra-abdominal pressure |
| **Genitourinary** | Increased urinary frequency due to increased total urinary output<br>Increased incidence of UTI and pyelonephritis due to urinary stasis (see *Urinary Tract Infection*, OB29)<br>Glycosuria that can be physiologic especially in the T3; consider testing for GDM if noted in first 2 trimesters<br>Ureters and renal pelvis dilation (R>L) due to progesterone-induced smooth muscle relaxation and uterine enlargement<br>Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmol/L), uric acid, and BUN |
| **Neurologic** | Increased incidence of carpal tunnel syndrome and Bell's palsy |
| **Endocrine** | Thyroid: moderate enlargement (not clinically detectable) and increased basal metabolic rate<br>Increased total thyroxine and thyroxine binding globulin (TBG)<br>Normal free thyroxine index and FSH levels<br>Adrenal: increased maternal cortisol throughout pregnancy (total and free)<br>Calcium: decreased total maternal $Ca^{2+}$ due to decreased albumin<br>Free ionized $Ca^{2+}$ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), resulting in increased bone resorption and gut absorption, and increased bone turnover (but no loss of bone density due to estrogen inhibition) (see *Diabetes Mellitus*, OB26) |

PVR – pulmonary vascular resistance; $FEV_1$ – forced expiratory volume in 1 second; CO – cardiac output; GFR – glomerular filtration rate; BUN – blood urea nitrogen

# Antepartum Care

- can be provided by an obstetrician, family physician, midwife, or multidisciplinary team (based on patient preference and risk factors)

### Preconception Counselling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
- **past medical history**: optimize medical conditions and review medications prior to pregnancy (see *Medical Complications of Pregnancy*, OB26, and *Medications*, OB49)
- supplementation
  - folic acid: encourage diet rich in folic acid and consider supplementation from 8-12 wk pre-conception until end of T1 to prevent NTD
    - 0.4-1 mg daily in all women; 5 mg if previous NTD, antiepileptic medications, DM, or BMI >35 kg/m$^2$
  - iron supplementation (in cases of iron deficiency anemia), prenatal vitamins
- **risk modification**
  - lifestyle/social: smoking, alcohol, drug use, domestic violence, occupational risks, poor social support, balanced nutrition, and physical fitness (see Family Medicine)
  - medications: discuss teratogenicity of medications so they may be adjusted, replaced, or stopped if necessary
  - infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV, TB testing based on travel and working in health care, history of varicella or vaccination, parvovirus immunity if exposed to small children, cytomegalovirus immunity if health care worker, and toxoplasmosis serology in case of proximity to cats or gardening
  - genetic testing as appropriate for high risk groups (see *Prenatal Screening*, Table 2); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay, birth anomalies, genetic diseases, and consanguinity

**Family doctors and midwives to consider OB consultation if:**
- Insulin-dependent GDM
- VBAC
- HTN
- Multiple gestation
- Malpresentation
- Active antepartum hemorrhage
- PTL/PPROM
- Failure to progress/descend
- Induction/augmentation if high risk
- Tears: 3rd or 4th degree
- Retained placenta

Note: Guidelines vary by institution and by provincial midwifery colleges

Advise all women capable of becoming pregnant to supplement their diet with 0.4 mg/d of folic acid (CTFPHC Grade II-2-A Evidence)

Prenatal and genetic screening are voluntary and require proper counselling and informed consent before proceeding HIV is done automatically in some provinces as opt-out testing; need to inform patient of this

# Initial Prenatal Visit

- usually within 8-12 wk of the 1st day of LMP or earlier if <20 or >35 yr old, bleeding, very nauseous, or other risk factors present

### History

- gestational age by dates from the 1st day of the LMP
  - Naegele's rule: 1st day of LMP + 1 year + 7 d – 3 mo
  - e.g. LMP = 1 Apr 2014, EDD = 8 Jan 2015 (modify if cycle >28 d by adding number of d >28)
  - EDD by LMP not reliable if irregular menstrual cycle, or if patient unsure of the LMP
- if LMP unreliable, get a dating U/S which could coincide with nuchal translucency at ~12 wk
- EDD by T1 U/S more reliable than LMP if difference is greater than 5 d from LMP due date
- history of present pregnancy (e.g. bleeding, N/V) and all previous pregnancies
- past medical, surgical, and gynecological history
- prescription and non-prescription medications
- family history: genetic diseases, birth defects, multiple gestation, and consanguinity
- social history: smoking, alcohol, drug use, and domestic violence (see Family Medicine)

In history of previous pregnancies, **ALWAYS** ask:
GTPAL
Year
Sex
Weight
Gestational age
Mode of delivery
Length of labour
Complications

### Physical Exam

- complete physical exam to obtain baseline patient information – BP and weight important for interpreting subsequent changes
- BMI for risk stratification (risk of DVT, GDM, and pre-eclampsia all increase with greater BMI)

Ask every woman about abuse – not just those whose situations raise suspicion of abuse AND ask as early as possible in pregnancy

### Investigations

- blood work
  - CBC, blood group and Rh status, antibody screen, and infection screening as per preconception counselling
- urine R&M, midstream urine C&S
  - screen for bacteriuria and proteinuria
- pelvic exam
  - Pap smear (only if required according to patient history and provincial screening guidelines), cervical or urine PCR for *N. gonorrhoeae* (GC) and *C. trachomatis*

**Estimated Date of Delivery (EDD) Determination**
- By LMP if menses regular, patient reliable historian
- By T1 U/S if irregular menses
- By embryo age and date of transfer if IVF

- T1 U/S up to 13+6/7 weeks GA is most accurate method of establishing GA
- Changes to the EDD must be documented and discussed with the patient
- Pregnancy without U/S confirming or revising the EDD prior to 22+0/7 GA is considered sub-optimally dated

# Nausea and Vomiting

### Epidemiology

- affects 50-90% of pregnant women
- often limited to T1 but may persist beyond this

### Management
- rule out other causes of N/V especially if refractory to initial therapy
- weigh frequently, assess level of hydration, and test urine for ketones
- non-pharmacological
  - frequent small meals (bland, dry, salty are better tolerated), encourage any safe appealing foods
  - electrolyte oral solutions (Pedialyte®, Gatorade®)
  - stop prenatal vitamins and if T1, substitute with folic acid or adult/children's vitamins that are low in iron
  - increase sleep/rest
  - ginger (maximum 1000 mg/d)
  - acupuncture, acupressure, and mindfulness-based cognitive therapy
- pharmacological
  - first line: pyridoxine (B6) monotherapy or doxylamine/pyridoxine (Diclectin) combination 4 tablets PO daily (1 q am, 1 q lunch and 2 qhs) up to maximum of 8 tablets/d
  - H1 receptor antagonists should be considered for acute or chronic episodes of N/V in pregnancy
  - metoclopramide and phenothiazines can be used as an adjunctive therapy for severe N/V in pregnancy
  - Ondansetron if severe N/V and other anti-emetics have failed
- severe/refractory
  - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

## Hyperemesis Gravidarum

### Definition
- intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

### Etiology
- multifactorial with hormonal, immunologic, and psychological components
- rapidly rising β-hCG ± estrogen levels may be implicated

### Investigations
- rule out systemic causes: GI, pyelonephritis, thyrotoxicosis
- rule out other obstetrical causes: multiple gestation, GTN, HELLP syndrome
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- U/S

### Management
- thiamine supplementation may be indicated
- non-pharmacological (see *Nausea and Vomiting*, OB4)
- pharmacological options
  - doxylamine/pyridoxine (for dosage, see *Nausea and Vomiting*, OB4)
  - dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
  - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
  - also consider: ondansetron or methylprednisolone (avoid steroids in T1 due to increased risk of oral clefting)
  - if severe: admit to hospital, NPO initially then small frequent meals; correct hypovolemia, electrolyte disturbance, and ketosis; TPN (if very severe) to reverse catabolic state

### Complications
- maternal
  - dehydration, electrolyte, and acid-base disturbances
  - Mallory-Weiss tear
  - Wernicke's encephalopathy, if protracted course
  - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight

## Subsequent Prenatal Visits

### Timing
- for uncomplicated pregnancies, SOGC recommends q4-6 wk until 30 wk, q2-3 wk from 30 wk, and q1-2 wk from 36 wk until delivery

### Assess at Every Visit
- estimated GA
- history: fetal movements, uterine bleeding, leaking, cramping, questions, concerns
- physical exam: BP, weight gain, SFH, Leopold's maneuvers (T3) for lie, position, and presentation of fetus
- investigations: urinalysis for proteinuria in high risk women; fetal heart rate starting at 10-12 wk using Doppler U/S

**Symphysis Fundal Height**

**Symphysis Fundal Height (SFH)**

| | |
|---|---|
| 12 wk | Uterine fundus at pubic symphysis |
| 20 wk | Fundus at umbilicus |
| 20-36 wk | SFH should be within 2 cm of GA |

**SFH< Dates**
- Date miscalculation
- IUGR
- Fetal demise
- Oligohydramnios
- Early engagement

**SFH> Dates**
- Date miscalculation
- Multiple gestation
- Polyhydramnios
- large for gestational age (familial, DM)
- Fibroids

### Leopold's Maneuvers
- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

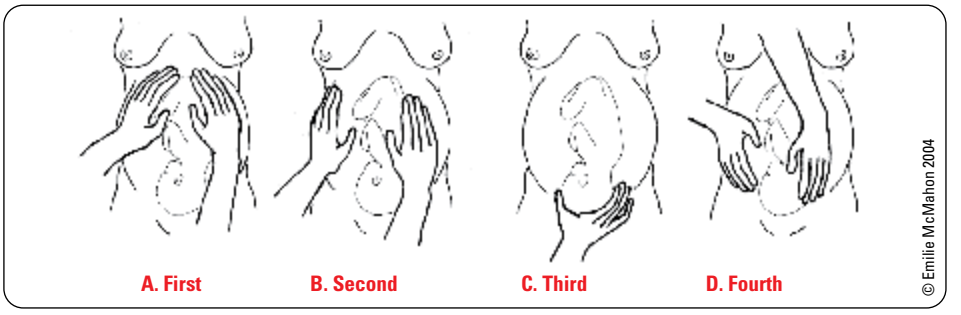

**Figure 2. Leopold's maneuvers (T3)**
Reprinted with permission from Essentials of Clinical Examination Handbook, 6th ed. Lincoln, McSheffrey, Tran, Wong

# Prenatal Screening and Diagnostic Tests

### Screening Tests
- testing should only occur following counselling and with informed consent from the patient

**Table 2. High-Risk Population Screening Tests**

| Disease (Inheritance) | Population(s) at Risk | Screening Test(s) |
|---|---|---|
| **Thalassemia (AR)** | Mediterranean, South East Asian, Western Pacific, African, Middle Eastern, Caribbean, South American | CBC (MCV and MCH), Hb electrophoresis, or HPLC |
| **Sickle Cell (AR)** | African, Caribbean, Mediterranean, Middle Eastern, Indian, South American | CBC (MCV and MCH), Hb electrophoresis, or HPLC |
| **Cystic Fibrosis (CF) (AR)** | Family history of CF in patient or partner or medical condition linked to CF like male infertility | CFTR gene DNA analysis |
| **Tay Sachs Disease (AR)** | Ashkenazi Jewish*, French Canadians, Cajun | Enzyme assay HEXA, or DNA analysis HEXA gene |
| **Fragile X Syndrome (X-linked)** | Family history – confirmed or suspected | DNA analysis: *FMR-1* gene |

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD); if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners are positive, refer for genetic counselling.

**Table 3. Gestation-Dependent Screening Investigations**

| Gestational Age (wk) | Investigations | Details |
|---|---|---|
| 8-12 | Dating U/S, possible Pap smear, chlamydia/gonorrhea testing, urine C&S (detect asymptomatic bacteriuria), HIV, VDRL, HepBsAg, Rubella IgG, Parvovirus IgM or IgG if high risk (small child at home or daycare worker/primary teacher), Varicella IgG if no history of disease/immunization, CBC, blood group and screen, urine C&S (detect asymptomatic bacteriuria) | |
| >10 | NIPT | Measures cell-free fetal DNA in maternal circulation |
| 10-12 | CVS | |
| 11-14 | Enhanced FTS<br>IPS Part 1 | Measures<br>1. Nuchal translucency on U/S<br>2. β-hCG<br>3. PAPP-A<br>4. Placental growth factor (enhanced FTS only)<br>5. MSAFP (enhanced FTS only) |
| 11-14 | Nuchal translucency U/S | |
| 15-16 to term | Amniocentesis | |
| 15-20 | IPS Part 2 | Measures<br>1. MSAFP<br>2. β-hCG<br>3. Unconjugated estrogen (estriol or μE3)<br>4. Inhibin A |

**Routine T2 U/S at 18-22 wk Helps Determine**
- Number of fetuses
- GA (if no prior U/S)
- Location of placenta
- Fetal anomalies

**Table 3. Gestation-Dependent Screening Investigations** (continued)

| Gestational Age (wk) | Investigations | Details |
|---|---|---|
| **15-20** | MSS | Measures<br>1. MSAFP<br>2. β-hCG<br>3. Unconjugated estrogen (estriol or μE3)<br>4. Inhibin A |
| **18-20 to term** | Fetal movements (quickening) | |
| **18-20** | U/S for dates, fetal growth, and anatomy assessment | |
| **24-28** | Gestational Diabetes Screen 50 g OGCT | See *Diabetes Mellitus*, OB26 |
| **28** | Repeat CBC<br>RhIG for all Rh-negative women | |
| **35-37** | GBS screen | See *Group B Streptococcus*, OB28 |
| **6 wk postpartum** | Discuss contraception, menses, breastfeeding, depression, mental health, support<br>Physical exam: breast exam, pelvic exam including Pap smear (only if due as per provincial screening) | |

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen

**DDx of Increased MSAFP**
- Incorrect GA
- >1 fetus (e.g. twins)
- Fetal demise
- ONTD
- Abdominal wall defects (e.g. omphalocele)

## ULTRASOUND SCREENING
- 8-12 wk GA: dating U/S (most accurate form of pregnancy dating)
- measurement of crown-rump length (margin of error: ± 5 d)
- EDD should be based on T1 U/S if available
- 11-14 wk GA: NTUS
- measures the amount of fluid behind the neck of the fetus
- early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner syndrome)
- NT measurement is necessary for the FTS and IPS Part 1
- 18-20 wk GA: growth and anatomy U/S (margin of error: ± 10 d)
- earlier or subsequent U/S performed when medically indicated

## NON-INVASIVE PRENATAL TESTING (NIPT)
- analyses maternal blood for circulating cell-free fetal DNA (ccffDNA) at 9-10 wk GA onwards. Requires dating U/S for accuracy

### Advantages
- increased accuracy (high detection rate (DR), low false positive rate [FPR]) highly sensitive for Trisomy 21 (DR 99%, FPR 0.1- can also look for Trisomy 18 (DR 96%, FPR 0.1%), 13 (DR 91%, FPR 0.1%), Turner syndrome (DR 90%, FPR 0.2%), and some other disorders (DiGeorge syndrome, Cri Du Chat, Prader-Willi, Angelman syndrome, XY disorders)
- increased positive predictive value
- earlier timing with results available in 1-2 weeks where parents can potentially have a CVS at 11-13 weeks for diagnosis over an amniocentesis after 15 weeks

### Disadvantages
- does not screen for ONTD
- high cost to patient (only covered in some provinces [ON and BC] in certain cases)
- need to confirm with invasive testing (it is a screening test, not a diagnostic test)
- does not test for all aneuploidies
- gives no result in 1-5% of cases (insufficient fetal fraction more common with elevated BMI)
- not applicable to donor eggs

**Table 4. Comparison of FTS, MSS, and IPS**

| eFTS | MSS | IPS |
|---|---|---|
| 11-14 wk | 15-20 wk | 11-13 wk U/S-nuchal translucency<br>11-14 wk: eFTS blood<br>15-20 wk: MSS blood including inhibin A |
| Risk estimate for<br>1. Down syndrome (Trisomy 21): increased NT, increased β-hCG, decreased PAPP-A<br>2. Trisomy 18: increased NT, decreased PAPP-A, decreased β-hCG<br><br>Note: does not measure risk of ONTD and should be combined with MSAFP at 15-20 wk<br>Useful when patient wants results within the T1<br>More accurate estimate of Down syndrome risk than MSS, sensitivity ~85% (when combined with age)<br>5% false positive rate<br>Patients with positive screen should be offered CVS, amniocentesis, or NIPT (covered in some provinces, self-pay in others) | Risk estimate for<br>1. ONTD: increased MSAFP (sensitivity 80-90%)<br>2. Trisomy 21: decreased MSAFP, increased β-hCG, decreased μE3 (sensitivity 65%)<br>3. Trisomy 18: decreased MSAFP, decreased β-hCG, decreased μE3, decreased inhibin A (sensitivity 80%)<br>Only offered alone if patient missed the time window for IPS or eFTS<br>8% baseline false positive rate for Trisomy 21, lower for NTD and Trisomy 18<br>Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others) | Risk estimate for ONTD, Trisomy 21, Trisomy 18<br>Sensitivity ~85-90%<br>2% false positive rate<br>Patients with positive screen should be offered U/S and/or amniocentesis or NIPT (covered in some provinces, self-pay in others) |

Note: In twins, eFTS, MSS, and IPS are not applicable; screen with NT, NIPT for chromosomal abnormalities and MSAFP for ONTDs

### Diagnostic Tests
- Diagnostic tests available:
  - amniocentesis
  - chorionic villus sampling

### Indications
- age >35 yr (increased risk of chromosomal anomalies)
  - risk factors in current pregnancy
  - abnormal U/S
- abnormal prenatal screen (IPS, eFTS, or MSS)
- past history/family history of:
  - chromosomal anomaly or genetic disease
  - either parent a known carrier of a genetic disorder or balanced translocation
  - consanguinity
  - >3 spontaneous abortions

## AMNIOCENTESIS
- U/S-guided transabdominal extraction of amniotic fluid performed as early as 15 weeks GA

### Indications
- identification of genetic and chromosomal anomalies (15-16 wk gestation) as per indications above
- confirmation of positive NIPT testing
- positive eFTS/IPS/MSS
- assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
  - if >2:1, RDS is less likely to occur

### Advantages
- also screens for ONTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

### Disadvantages
- 1/200 to 1/900 risk of procedure-related pregnancy loss, depending on local experience
- results take 14-28 d; QF-PCR or FISH can be done on chromosomes X, Y, 13, 18, 21, 22 to give preliminary results in 48 h

Compared to CVS, amniocentesis has a higher accuracy of prenatal cytogenetic diagnosis (99.8% vs. 97.5%) and lower risk of spontaneous abortion (0.5% vs. 1-2%)

**Risk Factors for Neural Tube Defects**

**GRIMM**
**G**enetics: family history of NTD (risk of having second child with NTD is increased to 2-5%), consanguinity, chromosomal (characteristic of Trisomy 13, 18, and 21)
**R**ace: European Caucasians > African Americans, 3-fold higher in Hispanics
**I**nsufficient vitamins: zinc and folate
**M**aternal chronic disease (e.g. DM)
**M**aternal use of antiepileptic drugs

General population risk for NTD is 0.1%

## CHORIONIC VILLUS SAMPLING
- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk

### Advantages
- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

### Disadvantages
- 1% risk of procedure-related pregnancy loss
- does not screen for ONTD
- 1-2% incidence of genetic mosaicism "false negative" results

## ISOIMMUNIZATION SCREENING

### Definition
- isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

### Etiology
- maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
- sensitization routes
  - incompatible blood transfusions
  - previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, abruption)
  - invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
  - any type of abortion
  - labour and delivery
  - trauma (e.g. car accident, fall, etc.)

**Rh Antibody Titre**
A positive titre (≥1:16) indicates an increased risk of fetal hemolytic anemia

### Investigations
- screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
- detailed U/S for hydrops fetalis
- middle cerebral artery Dopplers are done to assess degree of fetal anemia; if not available, bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
- cordocentesis for fetal Hb should be used cautiously (not first-line)

Standard dose of 300 µg of Rhogam® sufficient for 30 mL of fetal blood. Give additional 10 µg of Rhogam® for every mL of fetal blood over 30 mL

### Prophylaxis
- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (120-300 µg) given to all Rh negative and antibody screen negative women in the following scenarios:
  - routinely at 28 wk GA (provides protection for ~12 wk)
  - within 72 h of the birth of a Rh positive fetus
  - with any invasive procedure in pregnancy (CVS, amniocentesis)
  - as part of management of ectopic pregnancy
  - with miscarriage or therapeutic abortion
  - with an antepartum hemorrhage
  - with trauma
- Rhogam® 300 µg provides sufficient prophylaxis for 30 mL fetal Rh positive whole blood
- a Kleihauer-Betke test or flow cytometry can be used to measure the relative quantity of fetal blood in maternal circulation to determine if additional Rhogam® is indicated (if >30 mL fetal blood)
- if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy + U/S ± serial amniocentesis as needed (Rhogam® has no benefit, as B cells sensitized antibodies already in circulation)

### Treatment
- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion between 18-35 wk GA of O-negative packed RBCs may be required for severely affected fetus
- early delivery of the fetus for exchange transfusion following 35 wk GA

### Complications
- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to hydrops fetalis (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

## Fetal Surveillance

**DDx of Decreased Fetal Movements**

**DASH**
**D**eath of fetus
**A**mniotic fluid decreased
**S**leep cycle of fetus
**H**unger/Thirst

- patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus
- if the patient is concerned about decreased fetal movement, she is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk)
- all high-risk women should be told to do FM counts
  - ≥6 movements in 2 h expected
  - If there is a subjective decrease in fetal movement, time how long it takes to feel 10 discreet movements, laying on the left in a quiet setting may facilitate feeling subtle movements
  - if 10 movements take more than 2 h, further assessment is indicated, and patient should present to labour and delivery triage for non-stress test

### NON-STRESS TEST

Normal NST: 2 accels, >15 bpm from baseline, lasting >15 s in 20 min

### Definition
- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to fetal movement (see *Fetal Monitoring in Labour*, OB33)

**Describe NST**: baseline rate, absent/minimal/moderate/marked variability, accelerations present/not present, decelerations early/late/variable

### Indication
- any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being

**Table 5. Classification of Intrapartum EFM Tracings**

| | Normal Tracing (Category 1) | Atypical Tracing* (Category 2) | Abnormal Tracing* (Category 3) |
|---|---|---|---|
| **Baseline** | 110-160 bpm | 100-110 bpm or >160 bpm for <30 min<br>Rising baseline | Bradycardia <100 bpm<br>Tachycardia >160 for >30 min<br>Erratic baseline |
| **Variability** | 6-25 bpm (moderate)<br>≤5 (absent or minimal) for <40 min | 5 (absent or minimal) for 40-80 min | ≤5 for 80 min<br>Sinusoidal<br>25 bpm for >10 min |
| **Decelerations** | None or occasional variable <30 s | Variable decelerations<br>30-60 s duration | Variable decelerations >60 s<br>Late deceleration(s) |
| **Accelerations in Term Fetus** | 2 accelerations with acme of ≥15 bpm, lasting 15 s over <40 min of testing | 2 accelerations with acme of ≥15 bpm, lasting 15 s in 40-80 min | <2 accelerations with acme (peak) of contraction of ≥15 bpm, lasting 15 s in >80 min |
| **Accelerations in Preterm Fetus (<32 wk)** | >2 accelerations with acme of >10 bpm, lasting 10 s in <40 min | <2 accelerations with acme of >10 bpm, lasting 10 s in 40-80 min | <2 accelerations with acme of >10 bpm, lasting 10 s in >80 min |
| **Action** | FURTHER ASSESSMENT OPTIONAL, based on total clinical picture | FURTHER ASSESSMENT REQUIRED | URGENT ACTION REQUIRED An overall assessment of the situation and further investigation with U/S or BPP is required; some situations will require delivery |

Adapted from: SOGC, Fetal Health Surveillance: Antepartum and Intrapartum Consensus Guideline, September 2007

**Reassuring BPP (8/8)**

**LAMB**
**L**imb extension + flexion
**A**FV 2 cm x 2 cm
**M**ovement (3 discrete)
**B**reathing (one episode x 30 s)

Overlap >20 mm to the internal os in the T3 of pregnancy is highly predictive of the need for a C/S. Any degree of overlap after 35 wk is an indication for a C/S

### Operating Characteristics
- false positive rate depends on duration; false negative rate = 0.2-0.3%

### Interpretation
- normal: at least 2 accelerations of FHR >15 bpm from the baseline lasting >15 s in 20 min
- abnormal: <2 accelerations of FHR in 40 min
- if no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min

## BIOPHYSICAL PROFILE

### Definition
- U/S assessment of the fetus ± NST

### Indications
- post-term pregnancy
- decreased fetal movement
- IUGR
- any other suggestion of fetal distress or uteroplacental insufficiency

**Table 6. Scoring of the BPP**

| Parameter | Reassuring (2 points) |
|---|---|
| **Tone** | At least one episode of limb extension followed by flexion |
| **Movement** | Three discrete movements |
| **Breathing** | At least one episode of breathing lasting at least 30 s |
| **Amniotic Fluid Volume (AFV)*** | Fluid pocket of 2 cm in 2 axes |

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

### Interpretation
- 8: perinatal mortality rate 1:1000; repeat BPP as clinically indicated
- 6: perinatal mortality 31:1000; repeat BPP in 24 h
- 0-4: perinatal mortality rate 200:1000; deliver fetus if benefits of delivery outweigh risks

# Counselling of the Pregnant Woman

## Nutrition

- Canada's Food Guide to Healthy Eating suggests
  - eating a varied diet with plenty of vegetables and fruits, whole grains, dairy products, and lean meats or plant proteins
  - caloric increase of ~100 kCal/d in the T1, ~300 kCal/d in the T2 and T3, and ~450 kCal/d during lactation (less if BMI >25)
  - daily multivitamin with folic acid should be continued during pregnancy

### Nutrients in Pregnancy

- folate: 0.4-1 mg/d for first 12 wk (5 mg/d if high risk)
  - supports increase in blood volume, growth of maternal and fetal tissue, and decrease in incidence of NTD
  - foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, brussels sprouts, corn, and oranges
- calcium: 1200-1500 mg/d
  - maintains integrity of maternal bones, skeletal development of fetus, and breast milk production
- vitamin D: 1000 IU
  - promotes calcium absorption
- iron: 0.8 mg/d in T1, 4-5 mg/d in T2, and >6 mg/d in T3
  - supports maternal increase in blood cell mass, supports fetal and placental tissue
  - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
  - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see *Iron and Folate Deficiency Anemia*, OB26)
- essential fatty acids – supports fetal neural and visual development
  - contained in vegetable oils, margarines, peanuts, and fatty fish

### Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is considered safe
- relationship between caffeine and IUGR is unknown (ACOG)
- SOGC states 1-2 cups/d are safe during pregnancy

**Sources of Caffeine**
- 5 oz cup coffee: 40-180 mg
- 5 oz brewed tea: 20-90 mg
- 12 oz cola: 46 mg
- Red Bull®: 67 mg
- Dark chocolate bar: 10 mg
- 8 oz hot chocolate: 5 mg

### Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- raspberry leaf tea often used at term to promote labour
- herbal teas considered safe in moderation (2-3 cups/d): citrus peel, ginger, lemon balm, linden flower (unless cardiac condition), orange peel, and rose hip

### Foodborne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - listeriosis (*Listeria monocytogenes*) and toxoplasmosis (*Toxoplasma gondii*) are of concern during pregnancy
  - avoid consumption of raw meats and fish, raw hotdogs, raw eggs, raw sprouts (especially alfalfa), and unpasteurized dairy products or juices
  - avoid unpasteurized soft cheeses, deli meats, smoked salmon, and pâtés as they may be sources of Listeria
- chemical contamination of food
  - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, and tilefish

## Lifestyle

- exercise under physician guidance; "talk test" = should be able to speak while exercising; avoid supine position after 20 wk GA
- absolute contraindications
  - ruptured membranes, preterm labour, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28 wk, persistent T2 or T3 bleeding, uncontrolled type I DM, uncontrolled thyroid disease, serious cardiovascular or respiratory disease, and other systemic disorders

- relative contraindications
  - recurrent pregnancy loss, gestational hypertension, history of spontaneous preterm birth, mild/moderate cardiovascular or respiratory disease, symptomatic anemia, malnutrition, eating disorder, twin pregnancy after 28 wk, and other significant medical conditions
- weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
- work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
- air travel acceptable in T2; airline cut off for travel is 36-38 wk gestation depending on the airline, to avoid giving birth on the plane
- sexual intercourse: may continue, except in patients at risk for: abortion, preterm labour, or placenta previa; breast stimulation may induce uterine activity, and is discouraged in high-risk patients near term
- smoking: assist/encourage to reduce or quit smoking
  - increased risk of decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labour, and stillbirth
- alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
  - fetal alcohol syndrome (see Pediatrics, P24)
- cocaine: microcephaly, growth retardation, prematurity, and abruptio placentae
- marijuana: smoking associated with low birth weight infants
- biopsychosocial considerations: discuss birth plan, offer community maternal resources

**Weight Gain in Pregnancy**

| BMI | Total Gain | Weekly Gain in T2 & T3 |
|---|---|---|
| <18.5 | 28-40 lb | 1-1.3 lb/wk |
| 18.5-24.9 | 25-35 lb | 1 lb/wk |
| >25-29.9 | 15-25 lb | 0.5-0.7 lb/wk |
| >30 | 11-20 lb | 0.4-0.6 lb/wk |

# Medications

- most drugs cross the placenta to some extent
- very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
- use any drug with caution and only if necessary
- analgesics: acetaminophen preferable to ASA or ibuprofen

**Table 7. Documented Adverse Effects, Weigh Benefits vs. Risks, and Consider Medication Change**

| Contraindicated Medication | Adverse Effect |
|---|---|
| **ACE Inhibitor** | Fetal renal defects, IUGR, oligohydramnios |
| **Carbamazepine** | ONTD in 1-2% |
| **Chloramphenicol** | Grey baby syndrome (fetal circulatory collapse 2° to toxic accumulation) |
| **Lithium** | Ebstein's cardiac anomaly, goitre, hyponatremia |
| **Misoprostol** | Mobius syndrome (congenital facial paralysis with or without limb defects), spontaneous abortion, preterm labour |
| **NSAIDs** | Premature closure of the ductus arteriosus after 30 wk GA (prior to that, indomethacin used for tocolysis) |
| **Phenytoin** | Fetal hydantoin syndrome in 5-10% (IUGR, mental retardation, facial dysmorphogenesis, congenital anomalies) |
| **Retinoids (e.g. Accutane®)** | CNS, craniofacial, cardiac, and thymic anomalies |
| **Sulpha drugs** | Anti-folate properties, therefore theoretical risk in T1; risk of kernicterus in T3 |
| **Tetracycline** | Stains infant's teeth, may affect long bone development |
| **Valproate** | Congenital malformation (including ONTD) up to 9% |
| **Warfarin** | Increased incidence of spontaneous abortion, stillbirth, prematurity, IUGR, fetal warfarin syndrome (nasal hypoplasia, epiphyseal stippling, optic atrophy, mental retardation, intracranial hemorrhage) |

**Drug Resources During Pregnancy and Breastfeeding**
- Hale T. Medications and mothers' milk, 11th ed. Pharmasoft Publishing, 2004
- Lactmed: https://toxnet.nlm.nih.gov/newtoxnet/lactmed.htm

# Immunizations

## Intrapartum
- administration is dependent on the risk of infection vs. risk of immunization complications
- safe: tetanus toxoid, diphtheria, influenza, hepatitis B, and pertussis
- avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, and varicella
- contraindicated: oral typhoid
- the Public Health Agency of Canada recommends:
  - all pregnant women receive the influenza vaccine
  - all pregnant women should be given Tdap every pregnancy irrespective of immunization history ideally between 27-32 weeks but can be given at 13-26 weeks if high risk of preterm labour. If Tdap was given in T1 (i.e. prior to pregnancy recognition), it does not need to be repeated

## Postpartum
- rubella vaccine for all non-immune mothers. If they have had an adult booster and remain non-immune, they should not be revaccinated and pregnancy should be deferred for at least 1 mo following vaccination
- hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
- any vaccine required/recommended is generally safe postpartum

# Radiation

- ionizing radiation exposure is considered teratogenic at high doses
  - if indicated for maternal health, should be done
- imaging not involving direct abdominal/pelvic high dosage radiation is not associated with adverse effects
  - higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen/pelvis/lumbar spine
- radioactive isotopes of iodine are contraindicated
- no known adverse effects from U/S or MRI (long-term effects of gadolinium unknown, avoid if possible)

**Table 8. Approximate Fetal Doses from Common Diagnostic Procedures**

| Examination | Estimated Fetal Dose (cGy) | Number of Exams Safe in Pregnancy |
|---|---|---|
| **Plain Film** | | |
| Abdomen | 0-14 | 35 |
| Pelvis | 0-11 | 45 |
| Lumbar spine | 0-17 | 29 |
| Thoracic spine | 0.009 | 555 |
| Chest (2 views) | <0.001 | 5000 |
| **CT** | 0-8 | 6 |
| Abdomen | 2-5 | 2 |
| Pelvis | 0-24 | 20 |
| Lumbar spine | 0.006 | 833 |
| Chest | | |

Adapted from: Cohen-Kerem, et al. 2005 and Valentin 2000

**Radiation in Pregnancy**
- Necessary amount to cause miscarriage: >5 cGy
- Necessary amount to cause malformations: >20-30 cGy

# Obstetrical Hemorrhage

## Definition
- vaginal bleeding from 20 wk to term

## Differential Diagnosis
- bloody show (represents cervical changes/early stages of dilation) – most common etiology in T3
- placenta previa
- abruptio placentae – most common pathological etiology in T3
- vasa previa
- cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
- uterine rupture
- other: bleeding from bowel or bladder, abnormal coagulation

**Table 9. Comparison of Placenta Previa and Abruptio Placentae**

| | Placenta Previa | Abruptio Placentae |
|---|---|---|
| **Definition** | Abnormal location of the placenta near, partially, or completely over the internal cervical os | Premature separation of a normally implanted placenta after 20 wk GA |
| **Etiology** | Idiopathic | Idiopathic |
| **Epidemiology** | 0.5-0.8% of all pregnancies | 1-2% of all pregnancies |
| **Risk Factors** | History of placenta previa (4-8% recurrence risk)<br>Multiparity<br>Increased maternal age<br>Multiple gestation<br>Uterine tumour (e.g. fibroids) or other uterine anomalies<br>Uterine scar due to previous abortion, C/S, D&C, myomectomy | Previous abruption (recurrence rate 5-16%)<br>Maternal HTN (chronic or gestational HTN in 50% of abruptions) or vascular disease<br>Cigarette smoking (>1 pack/d), excessive alcohol consumption, cocaine<br>Multiparity and/or maternal age >35 yr<br>PPROM<br>Rapid decompression of a distended uterus (polyhydramnios, multiple gestation)<br>Uterine anomaly, fibroids<br>Trauma (e.g. motor vehicle collision, maternal battery) |
| **Bleeding** | PAINLESS | Usually PAINFUL |

# Placenta Previa

## Definition
- placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
- placental position is described in relation to the internal os as "mm away" or "mm of overlap"

## Clinical Features
- PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously but can become catastrophic
- mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
- physical exam
  - do not perform digital vaginal exam until ruling out placenta previa
  - uterus soft and non-tender
  - presenting fetal part high or displaced
  - FHR usually normal
  - shock/anemia correspond to degree of apparent blood loss
- complications
  - fetal
    - perinatal mortality low but still higher than with a normal pregnancy
    - prematurity (bleeding often dictates early C/S)
    - intrauterine hypoxia (acute or IUGR)
    - fetal malpresentation
    - PPROM
    - risk of fetal blood loss from placenta, especially if incised during C/S
  - maternal
    - <1% maternal mortality
    - hemorrhage and hypovolemic shock, anemia, acute renal failure, and pituitary necrosis (Sheehan syndrome)
    - placenta accreta – especially if previous uterine surgery or anterior placenta previa
    - hysterectomy

## Investigations
- transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
- spontaneously resolution is likely with increasing uterine distention if the placenta obscures the internal os by less than 20 mm at 20 wk GA
- transvaginal U/S should be repeated in the T3 as continued change in the placental location is likely

Do NOT perform a vaginal exam until placenta previa has been ruled out by U/S

## Management
- goal: keep pregnancy intrauterine until the risk of continuing pregnancy outweighs the risk of preterm delivery
- stabilize and monitor
  - maternal stabilization: large bore IV with hydration, $O_2$ for hypotensive patients
  - maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
  - electronic fetal monitoring
  - U/S assessment: when fetal and maternal conditions permit, determine fetal viability, GA, and placental position
- Rhogam® if mother is Rhnegative
- Kleihauer-Betke test to determine extent of fetomaternal transfusion and administer Rhogam® at adequate dose
- GA <37 wk and minimal bleeding: expectant management
  - admit to hospital
  - limited physical activity, no douches, enemas, or sexual intercourse
  - consider corticosteroids for fetal lung maturity
  - delivery when fetus is mature or hemorrhage indicating maternal or fetal compromise
- GA ≥37 wk – deliver by C/S

# Abruptio Placentae

## Definition
- partial or total placental detachment that is premature and caused by bleeding at the decidual-placental interface
- occurring >20 wk gestation

## Clinical Features
- classification
  - total (fetal death inevitable) vs. partial
  - external/revealed/apparent: blood dissects downward toward cervix
  - internal/concealed/occult (20%): blood dissects upward toward fetus, may or may not present with vaginal bleeding
  - most are mixed
- presentation
  - usually PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions/hypertonus
  - pain: sudden onset, constant, localized to lower back and uterus
  - shock/anemia out of proportion to apparent blood loss
  - ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  - ± coagulopathy

Abruptio placentae is the most common cause of DIC in pregnancy

## Complications
- fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
- maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), or amniotic fluid embolus

## Investigations
- clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

## Management
- maternal stabilization: large bore IV with hydration, $O_2$ for hypotensive patients
- maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, PTT/PT, platelets, fibrinogen, FDP, type and cross match)
- electronic fetal monitoring
- blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
- Rhogam® if Rh negative
  - Kleihauer-Betke test may confirm abruption
- abruption without fetal/maternal compromise (mild abruption)
  - GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  - GA ≥37 wk: stabilize and deliver
- abruption with fetal/maternal compromise (moderate to severe abruption)
  - hydrate and restore blood loss and correct coagulation defect if present
  - vaginal delivery if no contraindication and no evidence of fetal or maternal distress
  - C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress, or if vaginal delivery otherwise contraindicated

**Kleihauer-Betke Test**
Quantifies fetal cells in the maternal circulation

# Vasa Previa

## Definition
- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

## Epidemiology
- 1 in 5000 deliveries – higher in twin pregnancies

## Clinical Features
- PAINLESS vaginal bleeding and fetal distress (tachy-to-bradyarrhythmia in a sinusoidal pattern)
- if undiagnosed, 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)
- if diagnosed antenatally on U/S without labour or symptoms, then 97% survival

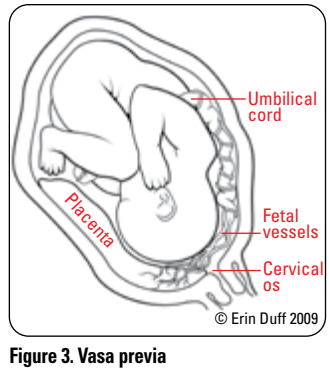

**Figure 3. Vasa previa**

## Investigations
- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright's stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

## Management
- planned C/S (35-36 weeks) or if bleeding, emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)

# Obstetrical Complications

## Preterm Labour

### Definition
- labour between 20 and 37 wk gestation

### Etiology
- idiopathic (most common)
- maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), HTN, DM, chronic illness, mechanical factors (previous obstetric, gynecological, and abdominal surgeries); socio-environmental (poor nutrition, smoking, drugs, alcohol, stress), pre-eclampsia
- maternal-fetal: PPROM (common), polyhydramnios, placenta previa, abruptio placentae, or placental insufficiency
- fetal: multiple gestation, congenital abnormalities, fetal hydrops
- uterine: excessive enlargement (hydramnios, multiple gestation), malformations (intracavitary leiomyomas, septate uterus, and Müllerian duct abnormalities)

### Epidemiology
- preterm labour complicates about 10% of pregnancies

### Risk Factors
- prior history of spontaneous PTL is the most important risk factor
- prior history of large or multiple cervical excisions (cone biopsy) or mechanical dilatation (D&C)
- cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
- identification of bacterial vaginosis and ureaplasma urealyticum infections
  - routine screening not supported by current data, but it is reasonable to screen high-risk women
- family history of preterm birth
- smoking
- late maternal age
- multiple gestation

### Prevention of Preterm Labour
**A. Cervical Cerclage**
- **definition**: placement of cervical sutures at the level of the internal os, usually at the end of the T1 or in the T2 and removed in the T3
- indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
- diagnosis of cervical incompetence
  - obstetrical Hx: silent cervical dilation, recurrent T2 losses, cervical procedures such as loop excisions
  - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
  - transvaginal U/S of cervical length is recommended only for high-risk pregnancies and only before 30 wk GA
- proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)

**B. Progesterone**
- progesterone thought to maintain uterine quiescence; however exact mechanism of action is unclear
- if previous PTL: 17-alphahydroxyprogesterone 250 mg IM weekly from 16+0 to 36 wk GA
- if short cervix: 200 mg daily vaginally from time of diagnosis to 36 wk GA
- superior to cerclage in preventing preterm labour of singletons not due to cervical incompetence

**C. Lifestyle Modification**
- smoking cessation, substance use reduction, treatment of GU infections (including asymptomatic UTIs), and patient education regarding risk factors

### Predicting PTL
- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue
  - positive if >50 ng/mL; NPV > PPV
  - done if 1 or more signs of preterm labour (regular contractions >6/h, pelvic pressure, low abdominal pain and/or cramps, low backache)
  - done only if: 24-34 weeks, intact membranes, <3 cm dilated, established fetal well being
  - contraindicated as well if: cerclage, active vaginal bleeding, vaginal exam, or sex in last 24 h
  - if negative, not likely to deliver in 7-14 d (>95% accuracy); if positive increased risk of delivery, may need admission/transfer to centre that can do delivery ± tocolysis and/or corticosteroids

### Clinical Features
- regular contractions (2 in 10 min, >6/h)
- cervix >1 cm dilated, >80% effaced, or length <2.5 cm

Preterm labour is the most common cause of neonatal mortality in the US

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk gestation predicted spontaneous PTL at <34 wk with sensitivity of 23%, specificity of 97%, PPV of 25%, NPV of 96%

**Ultrasonographic Cervical Length Assessment in Predicting Preterm Birth in Singleton Pregnancies**
J Obstet Gynaecol Can 2018;40(2);154-61
**Recommendations:**
1. Transabdominal ultrasonography should not be used for cervical length assessment to predict preterm birth (II-2D).
2. Transvaginal ultrasonography is the preferred route for cervical assessment to identify women at increased risk of spontaneous preterm birth and may be offered to women at increased risk of preterm birth (II-2B).
3. Transperineal ultrasonography may be offered to women at increased risk of preterm birth if transvaginal ultrasonography is either unacceptable or unavailable (II-2B).
4. Because of poor positive predictive values and sensitivities and lack of proven effective interventions, routine transvaginal cervical length assessment is not recommended in women at low risk (II-2E).
5. In women presenting with suspected preterm labour, transvaginal sonographic assessment of cervical length may be used to help in determining who is at high risk of preterm delivery and may be helpful in preventing unnecessary intervention. It is unclear whether this information results in a reduced risk of preterm birth (II-2B).
6. In asymptomatic women with a history of spontaneous preterm birth and an ultrasonographically diagnosed short cervical length (<25 mm) prior to 24 weeks of gestation, cervical cerclage should be considered to reduce the risk of preterm birth (I-B).
7. In all asymptomatic women who present with membranes at or protruding past the external cervical os, an emergency cerclage should be considered to reduce the risk of preterm delivery (I-B).

## Management

**A. Initial**

- transfer to appropriate facility if stable
  - tocolysis and first dose of antenatal steroids prior to transfer
- hydration (normal saline at 150 mL/h)
- bed rest in left lateral decubitus position to reduce aortocaval compression and improve cardiac output
- sedation (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BPP, position, placenta location, estimated fetal weight)
- prophylactic antibiotics; (for GBS) important to consider if PPROM (e.g. erythromycin controversial, but may help to delay delivery)

**B. Tocolysis (Suppression of Labour)**

- does not inhibit preterm labour completely, but may delay delivery (used for <48 h) to allow for betamethasone valerate (Celestone®) and/or transfer to appropriate centre for care of the premature infant
- requirements (all must be satisfied)
  - preterm labour
  - live, immature fetus, intact membranes, cervical dilatation of <4 cm
  - absence of maternal or fetal contraindications
- contraindications
  - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preeclampsia or eclampsia, chorioamnionitis
  - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
- agents
  - calcium channel blockers: nifedipine
    - 20 mg PO loading dose followed by 20 mg PO 90 min later
    - 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
    - 10 mg PO q20min x 4 doses
    - relative contraindications: nifedipine allergy, hypotension, hepatic dysfunction, concurrent beta-mimetics or magnesium sulfate use, transdermal nitrates, or other antihypertensive medications
    - absolute contraindications: maternal congestive heart failure, aortic stenosis
  - prostaglandin synthesis inhibitors: indomethacin
    - 1st line for early preterm labour (<30 wk GA) or polyhydramnios
    - 50-100 mg PR loading dose followed by 25-50 mg q6h x 8 doses for 48 hours

**C. Antenatal Corticosteroids**

- betamethasone valerate (Celestone®) 12 mg IM q24h x 2 doses or dexamethasone 6 mg IM q12h x 4 doses
  - given between 24 to 33+6 wk GA if expected to deliver in the next 7 d
  - women between 22+0 and 23+6 wk GA at high risk of preterm birth within the next 7 d should be provided with multidisciplinary consultation regarding high likelihood for severe perinatal morbidity and mortality and associated maternal morbidity – consider antenatal corticosteroids therapy if early intensive care is requested and planned
  - specific maternal contraindications: active TB
- enhance fetal lung maturity, reduce perinatal death, reduce incidence of severe RDS, and intraventricular hemorrhage, necrotizing enterocolitis, and neonatal sepsis

**D. Neuroprotection**

- $MgSO_4$ 4 g bolus followed by 1 g/h infusion for at least 4 h if imminent delivery expected and <32 wk GA

## Prognosis

- prematurity is the leading cause of perinatal morbidity and mortality
- 24 wk = 50% survival (may be higher in tertiary care centres with level 3-4 NICU)
- 30 wk or 1500 g (3.3 lb) = 90% survival
- 33 wk or 2000 g (4.4 lb) = 99% survival
- morbidity due to asphyxia, hypoxia, sepsis, RDS, intraventricular cerebral hemorrhage, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

**Cerclage for Short Cervix on Ultrasonography in Women with Singleton Gestations and Previous Preterm Birth**
Obstet Gynecol 2011;117:663-71
**Purpose**: To determine if cerclage prevents preterm birth (<35 wk gestation) and perinatal mortality and morbidity among women with previous spontaneous preterm birth, asymptomatic singleton gestation, and short cervical length (<25 mm before 24 wk gestation) on transvaginal ultrasonography.
**Methods**: Meta-analysis of randomized trials identified using searches on MEDLINE, PUBMED, EMBASE, and the Cochrane Library.
**Results**: 5 trials included. Preterm birth was significantly lower among women receiving cerclage vs. those not receiving (RR = 0.70, 95% CI 0.55-0.89). Cerclage also significantly reduced preterm birth before 24, 28, 32, and 37 wk gestation. Perinatal mortality and morbidity were significantly lower in the cerclage group (RR = 0.64, 95% CI 0.45-0.91).
**Conclusions**: Cerclage significantly prevents preterm birth and perinatal mortality and morbidity in this specific group of women.

**Tocolytics for Preterm Premature Rupture of Membranes**
Cochrane DB Syst Rev 2014;2:CD007062
**Purpose**: To assess the potential benefits and harms of tocolysis in women with PPROM.
**Selection Criteria**: Pregnant women with singleton pregnancies and PPROM (23-36 wk and 6 d GA).
**Results**: 8 studies with 408 women total. Prophylactic tocolysis with PPROM was associated with increased overall latency, without additional benefits for maternal/neonatal outcomes. For women with PPROM before 34 wk, there was a significantly increased risk of chorioamnionitis in women who received tocolysis. Neonatal outcomes were not significantly different.
**Conclusion**: Although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPROM, as there was an increase in maternal chorioamnionitis without significant benefits to the infant.

# Premature Rupture of Membranes

## Definitions

- PROM: premature (pre-labour) rupture of membranes at any GA
- prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
- preterm ROM: ROM occurring before 37 wk gestation
- PPROM: preterm (before 37 wk) AND premature (pre-labour) rupture of membranes

**Membrane status determined by**

- Pooling of fluid on speculum exam
- Increased pH of vaginal fluid (nitrazine test)
- Ferning of fluid under light microscopy
- Decreased AFV on U/S

## Risk Factors

- maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
- fetal: congenital anomaly, multiple gestation
- other risk factors associated with PTL

## Clinical Features

- history of fluid gush or continued leakage

### Investigations
- sterile speculum exam (avoid introduction of infection)
  - pooling of fluid in the posterior fornix
  - cascading: fluid leaking out of cervix with cough/valsalva
- nitrazine (basic amniotic fluid turns nitrazine paper blue)
  - low specificity as it can also be positive with blood, urine, or semen
- ferning: salt in amniotic fluid evaporates, giving amniotic fluid the appearance of ferns on microscopy
- U/S to rule out fetal anomalies; assess GA, presentation, and BPP

### Management
- admit for expectant management and monitor vitals q4h, daily NST, WBC count, increased surveillance
- avoid introducing infection by minimizing examinations
  - consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <34 weeks if no evidence of infection
  - consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
- screen women for UTIs, STIs, GBS infection and treat with appropriate antibiotics if positive (treat GBS at time of labour)
- if not in labour or labour not indicated, consider antibiotics: penicillins or macrolide antibiotics are the antibiotics of choice
- deliver urgently if evidence of fetal distress and/or chorioamnionitis

**Table 10. PROM Management**

| Degree of Prematurity | Management |
|---|---|
| 22-25 wk | Individual consideration with counselling of parents regarding risks to preterm infants |
| 26-34 wk | Expectant management as prematurity complications are significant |
| 34-36 wk | "Grey zone" where risk of death from RDS and neonatal sepsis is the same |
| ≥37 wk | Induction of labour since the risk of death from sepsis is greater than RDS |

### Prognosis
- varies with gestational age
- 90% of women with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
- 50% of women with PROM at <26 wk GA go into spontaneous labour within 1 wk
- complications: cord prolapse, intrauterine infection (chorioamnionitis), premature delivery, limb contracture, and pulmonary hypoplasia especially at very early gestation

**Antibiotic Therapy in Preterm Premature Rupture of the Membranes**
J Obstet Gynaecol Can 2017;39(9):207-12
**Recommendations:**
1. Following PPROM at 32 weeks' gestation, antibiotics should be administered to women who are not in labour in order to prolong pregnancy and to decrease maternal and neonatal morbidity.
2. The benefit of antibiotics is greater at earlier gestational ages.
3. Antibiotics of choice are penicillins or macrolide antibiotics (erythromycin) in parenteral and/or oral forms. In patients allergic to penicillin, macrolide antibiotics should be used alone.
4. Two possible regimen options from large PPROM RCTs are: (1) ampicillin 2g IV q6h and erythromycin 250 mg IV q6h for 48 hours followed by amoxicillin 250 mg orally q8h and erythromycin 333 mg orally q8h for 5 d; (2) erythromycin 250 mg orally q6h for 10 d.
5. Amoxicillin/clavulanic acid should not be used because of an increased risk of necrotizing enterocolitis in neonates. Amoxicillin without clavulanic acid is safe.
6. Women presenting with PPROM should be screened for urinary tract infections, sexually transmitted infections, and group *B streptococcus*.

# Postterm Pregnancy

### Definition
- pregnancy >42 wk GA

### Epidemiology
- 41 wk GA: up to 27%
- >42 wk GA: 5.5%

### Etiology
- most cases idiopathic
- anencephalic fetus with no pituitary gland
- placental sulfatase deficiency (X-linked recessive condition in 1/2000-1/6000 infants) – rare

### Management (for singleton, cephalic fetus, otherwise uncomplicated)
- GA 39 wk with advanced maternal age (>40 y): consideration should be given to IOL due to increased risk of stillbirth
- GA 40-41 wk: expectant management
  - no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
- GA >41 wk: offer IOL if vaginal delivery is not contraindicated
  - IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia, and death when compared with expectant management
- GA >41 wk and expectant management elected: serial fetal surveillance
  - fetal movement count by the mother
  - BPP q3-4d
- if AFI is decreased, labour should be induced

### Prognosis
- if >42 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries, pneumonia, seizures, requirement of NICU admission, stillbirth
- morbidity increased with HTN in pregnancy, DM, abruption, IUGR, and multiple gestation

# Intrauterine Fetal Demise

### Definition
- fetal demise in utero after 20 wk GA (before 20 wk GA called spontaneous abortion)

### Epidemiology
- occurring in 1% of pregnancies

### Etiology
- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, and APS

### Clinical Features
- decreased perception of fetal movement by mother
- SFH and maternal weight not increasing
- absent fetal heart tones on Doppler (not diagnostic)
- high MSAFP
- on U/S: no fetal heart rate. Depending on timing of death, may see skull collapse, brain tissue retraction, empty fetal bladder, non-filled aorta, or poor visualization of midline flax

### Management
- diagnosis: absent cardiac activity and fetal movement on U/S (required)
- determine secondary cause
  - maternal: HbA1c, fasting glucose, TSH, Kleihauer-Betke, VDRL, ANA, CBC, anticardiolipins, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, and TORCH screen
  - fetal: karyotype, cord blood, skin biopsy, genetics evaluation, autopsy, amniotic fluid culture for CMV, parvovirus B19, and herpes
  - placenta: pathology, bacterial cultures

### Treatment
- <12 wk: dilation and curettage
- 13-20 wk: dilation and evacuation or sometimes IOL
- >20 wk: IOL
- monitor for maternal coagulopathy (10% risk of DIC)
- parental psychological care/bereavement support as per hospital protocol
- comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

**DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors**

**Obstetrical Causes**
- Abruption
- Gestational HTN
- Fetal demise
- PPH

**DIC-specific Blood Work**
- Platelets
- aPTT and PT
- FDP
- Fibrinogen

**Treatment**
- Treat underlying cause
- Supportive
- Fluids
- Blood products
- FFP, platelets, cryoprecipitate
- Consider anti-coagulation as VTE prophylaxis

# Intrauterine Growth Restriction

### Definition
- estimated fetal weight <10th percentile for GA on U/S, has not reached biologically determined growth potential

### Etiology/Risk Factors
- 50% unknown
- maternal causes
  - malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, type 1 DM, SLE, pulmonary insufficiency, previous IUGR (25% risk, most important risk factor), and chronic HTN
- maternal
  - gestational HTN, chronic renal insufficiency, prolonged gestation, substance abuse, and poor nutrition
- placental
  - any disease that causes placental insufficiency
  - gross placental morphological abnormalities (infarction, hemangiomas, placenta previa, ansd abnormal cord insertion)
- fetal causes
  - TORCH infections, multiple gestation, and congenital anomalies/chromosomal abnormalities (10%)

### Clinical Features
- symmetric/type I (25-30%): occurs early in pregnancy
  - reduced growth of both head and abdomen
  - head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
  - usually associated with congenital anomalies or TORCH infections
- asymmetric/type II (70%): occurs late in pregnancy
  - fetal abdomen is disproportionately smaller than fetal head
  - brain is spared; therefore head:abdomen ratio increased
  - usually associated with placental insufficiency
  - more favourable prognosis than type I

**TORCH**
**T**oxoplasmosis
**O**thers: e.g. syphilis
**R**ubella
**C**MV
**H**SV
• See Table 15, OB29

- complications
  - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, hypocalcemia, hypophosphatemia, hyponatremia, and mental retardation
  - greater risk of perinatal morbidity and mortality

### Investigations
- SFH measurements at every antepartum visit (ensure accurate GA)
- if mother at high risk or SFH lags >2 cm behind GA
  - U/S for biparietal diameter, head and abdominal circumference ratio, femur length, fetal weight, AFV (decrease associated with IUGR), and decrease in the rate of growth
  - ± BPP
  - Doppler analysis of umbilical cord blood flow

### Management
- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
- as IUGR fetuses are less likely to withstand stresses of labour, they are more likely to be delivered by Cesarean section

## Macrosomia

### Definition
- infant weight ≥90th percentile for a particular GA or >4000 g

### Etiology/Risk Factors
- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity

### Clinical Features
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Table 14, OB28)

### Investigations
- serial SFH
- further investigations if mother at high risk or SFH >2 cm ahead of GA
- U/S predictors
  - polyhydramnios
  - T3 abdominal circumference >1.5 cm/wk
  - head circumference/abdominal circumference ratio <10th percentile
  - femur length/abdominal circumference ratio <20th percentile

### Management
- prevent hyperglycemia in women with DM, optimize pre-pregnancy weight, and limit pregnancy weight gain
- prophylactic C/S is a reasonable option where EFW >5000 g in non-diabetic woman and EFW >4500 g in diabetic woman
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, need for person-centred and shared decision-making

# Polyhydramnios/Oligohydramnios

**Table 11. Polyhydramnios and Oligohydramnios**

| | Polyhydramnios | Oligohydramnios |
|---|---|---|
| **Definition** | AFI >25 cm<br>U/S: single deepest pocket >8 cm | AFI <5 cm<br>U/S: single deepest pocket ≤2 cm |
| **Etiology** | Idiopathic most common<br>Maternal<br>Type 1 DM: abnormalities of transchorionic flow<br>Maternal-fetal<br>Chorioangiomas<br>Multiple gestation<br>Fetal hydrops (increased erythroblastosis)<br>Fetal<br>Chromosomal anomaly (up to 2/3 of fetuses have severe polyhydramnios)<br>Respiratory: cystic adenomatoid malformed lung<br>CNS: anencephaly, hydrocephalus, meningocele<br>GI: tracheoesophageal fistula, duodenal atresia, facial clefts (interfere with swallowing) | Idiopathic most common<br>Maternal<br>Uteroplacental insufficiency (preeclampsia, nephropathy)<br>Medications (ACEI)<br>Fetal<br>Congenital urinary tract anomalies (renal agenesis, obstruction, posterior urethral valves)<br>Demise/chronic hypoxemia (blood shunt away from kidneys to perfuse brain)<br>IUGR<br>Ruptured membranes: prolonged amniotic fluid leak<br>Amniotic fluid normally decreases after 35 wk |
| **Epidemiology** | Occur in 0.2-1.6% of all pregnancies | Occur in ~4.5% of all pregnancies<br>Severe form in <0.7%<br>Common in pregnancies >41 wk (~12%) |
| **Clinical Features and Complications** | Uterus large for dates, difficulty palpating fetal parts and hearing FHR<br>Maternal complications<br>Pressure symptoms from overdistended uterus (dyspnea, edema, hydronephrosis)<br>Obstetrical complications<br>Cord prolapse, placental abruption, malpresentation, preterm labour, uterine dysfunction, and PPH | Uterus small for dates<br>Fetal complications<br>15-25% have fetal anomalies<br>Amniotic fluid bands (T1) can lead to Potter's facies, limb deformities, abdominal wall defects<br>Obstetrical complications<br>Cord compression<br>Increased risk of adverse fetal outcomes<br>Pulmonary hypoplasia (late-onset)<br>Marker for infants who may not tolerate labour well |
| **Management** | Determine underlying cause<br>Screen for maternal disease/infection<br>Complete fetal U/S evaluation<br>Depends on severity<br>Mild to moderate cases require no treatment<br>If severe, hospitalize and consider therapeutic amniocentesis | Always warrants admission and investigation<br>Rule out ROM<br>Fetal monitoring (NST, BPP)<br>U/S Doppler studies (umbilical cord and uterine artery)<br>Maternal hydration with oral or IV fluids to help increase amniotic fluid<br>Injection of fluid via amniocentesis will improve condition for ~1 wk – may be most helpful for visualizing any associated fetal anomalies<br>Consider delivery if term<br>Amnio-infusion may be considered during labour via intrauterine catheter |
| **Prognosis** | 2-5 fold increase in risk of perinatal mortality | Poorer with early onset<br>High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2 |

# Multi-Fetal Gestation and Malpresentation

## Epidemiology

- incidence of twins is 1/80 and triplets 1/6400 in North America
- 2/3 of twins are dizygotic (fraternal)
  - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, and ethnicity (e.g. certain African regions)
- monozygous twinning occurs at a constant rate worldwide (1/250)
- determine zygosity by number of placentas, thickness of membranes, sex, and blood type

## Clinical Features

**Table 12. Complications Associated with Multiple Gestation**

| Maternal | Uteroplacental | Fetal |
|---|---|---|
| Hyperemesis gravidarum<br>GDM<br>Gestational HTN<br>Anemia<br>Increased physiological stress on all systems<br>Increased compressive symptoms<br>C/S | Increased PROM/PTL<br>Polyhydramnios<br>Placenta previa<br>Placental abruption<br>PPH (uterine atony)<br>Umbilical cord prolapse<br>Cord anomalies (velamentous insertion, 2 vessel cord) | Prematurity<br>IUGR<br>Malpresentation<br>Congenital anomalies<br>Twin-twin transfusion<br>Increased perinatal morbidity and mortality<br>Twin interlocking (twin A breech, twin B vertex)<br>Single fetal demise |

### Management
- U/S determination of chorionicity must be done within T1 (ideally 8-12 wk GA)
- increased antenatal surveillance
  - serial U/S q3-4wk from 22 wk GA to assess growth (uncomplicated diamniotic dichorionic)
  - increased frequency of U/S in monochorionic diamniotic and monochorionic monoamniotic twins
  - Doppler flow studies weekly if discordant fetal growth (>30%)
  - BPP as needed
- may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 10% of cases have twin A delivered vaginally and twin B delivered by C/S)
- mode of delivery depends on fetal weights, GA, and presentation

**The Ps of Multiple Gestation Complications**

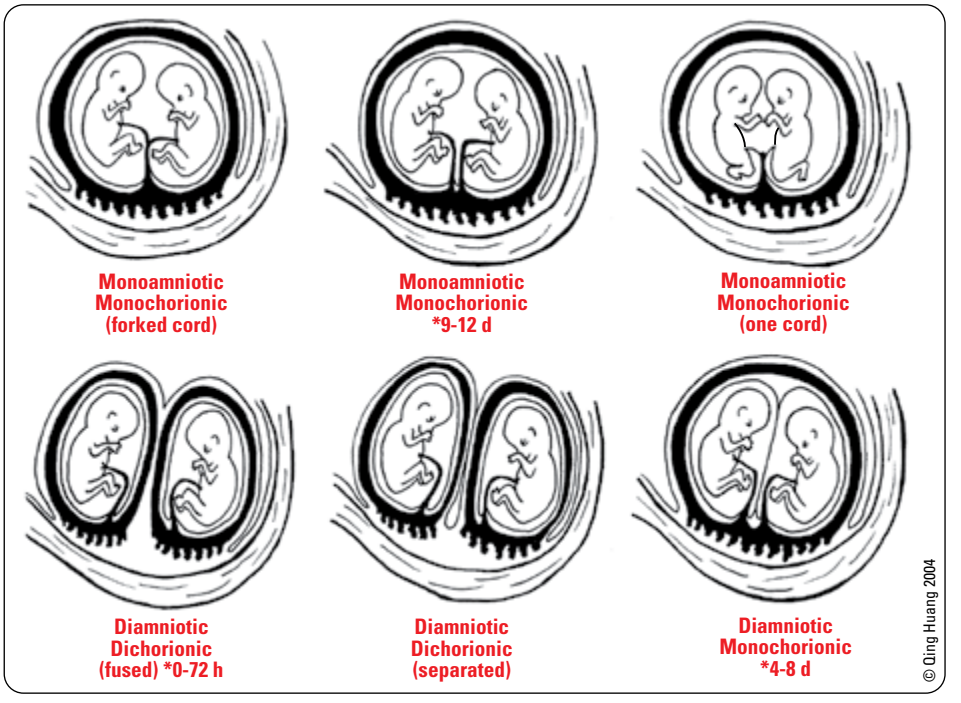

**Figure 4. Classification of twin pregnancies** ***Indicates time of cleavage**

## Twin-Twin Transfusion Syndrome

### Definition
- formation of placental intertwin vascular anastomoses causes arterial blood from donor twin to pass into veins of the recipient twin

### Epidemiology
- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

### Clinical Features
- donor twin: IUGR, hypovolemia, hypotension, anemia, and oligohydramnios
- recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, and kernicterus in neonatal period

### Investigations
- detected by U/S screening, Doppler flow analysis

### Management
- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary
- laparoscopic occlusion of placental vessels
- fetoscopic laser ablation of placental vascular anastomoses when indicated and if available

# Breech Presentation

## Definition
- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): hips and knees both flexed
- frank (60%): hips flexed, knees extended, buttocks present at cervix
  - most common type of breech presentation
  - most common breech presentation to be delivered vaginally
- incomplete (30%): both or one hip partially flexed and both or one knee present below the buttocks, feet or knees present first (footling breech, kneeling breech)

## Epidemiology
- occurs in 3-4% of pregnancies at term (25% <28 wk)

## Risk Factors
- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumours, fibroids, previous breech), pelvic tumours causing compression, and grand multiparity
- placental: placenta previa
- fetal: prematurity, amniotic fluid (poly-/oligohydramnios), multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy, hydrocephalus, and anencephalus

## Management
- ECV (external cephalic version): repositioning of singleton fetus within uterus under U/S guidance
  - overall success rate of ~60%
  - criteria: >36 wk GA, singleton, unengaged presenting part, reactive NST, not in labour
  - absolute contraindications: where C/S is required (placenta previa, previous classical C/S), previous myomectomy, PROM, uteroplacental insufficiency, nuchal cord, non-reactive NST, multiple gestation
  - relative contraindications: mild/moderate oligohydramnios, suspected IUGR, HTN, previous T3 bleed
  - risks: abruption, cord compression, cord accident, ROM, labour, fetal bradycardia requiring C/S (<1% risk), alloimmunization, fetal death (1:5000)
  - method: tocometry, followed by U/S guided transabdominal manipulation of fetus with constant fetal heart monitoring
  - if patient Rh negative, give Rhogam® after the procedure
  - better prognosis if multiparous, good fluid volume, small baby, skilled obstetrician, and posterior placenta
- pre-or early-labour U/S to assess type of breech presentation, fetal growth, estimated weight, placenta position, attitude of fetal head (flexed is preferable); if U/S unavailable, recommend C/S
- ECV and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent
- method for vaginal breech delivery
  - encourage effective maternal pushing efforts
  - at delivery of head (after feet), assistant must apply suprapubic pressure to flex and engage fetal head
  - delivery can be spontaneous or assisted; avoid fetal traction
  - apply fetal manipulation only after spontaneous delivery to level of umbilicus
- contraindications to vaginal breech delivery
  - cord presentation
  - clinically inadequate maternal pelvis
  - fetal factors incompatible with vaginal delivery (e.g. hydrocephalus, macrosomia, fetal growth restriction)
- C/S recommended if: the breech has not descended to the perineum in the second stage of labour after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing

## Prognosis
- regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption, and cord prolapse

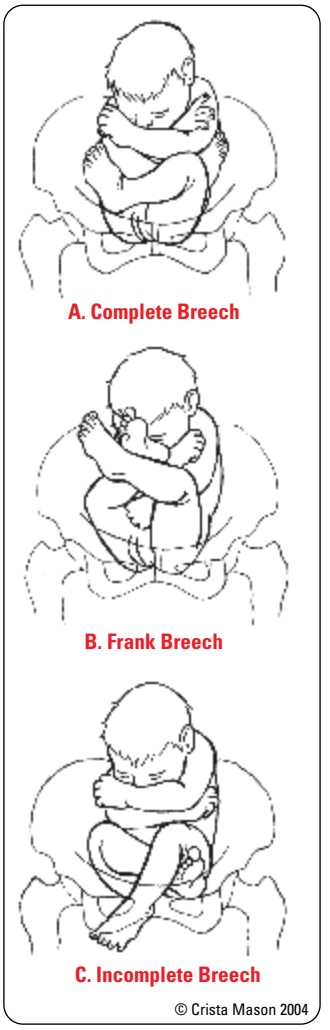

**Figure 5. Types of breech presentation**

**Criteria for Vaginal Breech Delivery**
- Frank or complete breech, GA >36 wk
- EFW 2500-3800 g based on clinical and U/S assessment (5.5–8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- 2 experienced obstetricians, assistant, and anesthetist present
- Ability to perform emergency C/S within 30 min if required

# Hypertensive Disorders of Pregnancy

## Hypertension in Pregnancy

- hypertensive disorders of pregnancy are classified as either pre-existing or gestational HTN. Pre-eclampsia and eclampsia are included in the spectrum of hypertensive disorders of pregnancy

**Ominous Symptoms of HTN in Pregnancy**
RUQ pain, headache, and visual disturbances

### PRE-EXISTING HYPERTENSION

#### Definition
- BP ≥140/90 prior to 20 wk GA; BP should be elevated on ≥2 occasions at least 15 minutes apart
- essential HTN is associated with an increased risk of gestational HTN, abruptio placentae, IUGR, and IUFD

### GESTATIONAL HTN

#### Definition
- sBP ≥140 or dBP ≥90 after 20 wk GA without proteinuria in a woman known to be normotensive before pregnancy

### PREECLAMPSIA
#### Definition
- pre-existing or gestational HTN with new onset proteinuria or adverse conditions (end organ dysfunction)

### ECLAMPSIA
#### Definition
- the occurrence of ≥1 generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

**Note**
Eclampsia prior to 20 wk of gestation is rare and should raise the possibility of an underlying molar pregnancy or antiphospholipid syndrome

#### Epidemiology of Eclampsia
- an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

#### Clinical Manifestation of Eclampsia
- eclampsia is a clinical diagnosis
- typically tonic-clonic and lasting 60-75 s
- symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
- in up to one third of cases, there is no proteinuria or blood pressure >140/90 mmHg prior to the seizure
- in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

#### Risk Factors for Hypertensive Disorders in Pregnancy
- maternal factors
  - primigravida (80-90% of gestational HTN), first conception with a new partner, PMHx or FHx of gestational HTN, or preeclampsia/eclampsia
  - DM, chronic HTN, or renal insufficiency
  - obesity
  - antiphospholipid syndrome or inherited thrombophilia
  - extremes of maternal age (<18 or >35 yr)
  - previous stillbirth or IUFD
  - vascular or connective tissue disease
- fetal factors
  - IUGR or oligohydramnios
  - GTN
  - multiple gestation
  - fetal hydrops "mirror syndrome"
  - abruptio placentae

**Hypertension in Pregnancy**

**Adverse Maternal Conditions**
- sBP >160 mmHg
- dBP >100 mmHg
- HELLP
- Cerebral hemorrhage
- Renal dysfunction: oliguria <500 mL/d
- Left ventricular failure, pulmonary edema
- Placental abruption, DIC
- **Symptoms**
  - Abdominal pain, N/V
  - Headaches, visual problems
  - SOB, chest pain
  - Eclampsia: convulsions

**Adverse Fetal Conditions**
- IUGR
- Oligohydramnios
- Absent/reversed umbilical artery end diastolic flow
- **Can result in:**
  - Fetal disability and/or death

#### Clinical Evaluation of Hypertensive Disorders in Pregnancy
- in general, clinical evaluation should include the mother and fetus
- evaluation of mother:
  - body weight
  - central nervous system
    - presence and severity of headache
    - visual disturbances – blurring, scotomata

        - tremulousness, irritability,and somnolence
        - hyperreflexia
    - hematologic
        - bleeding, petechiae
    - hepatic
        - RUQ or epigastric pain
        - severe N/V
    - renal
        - urine output and colour
- evaluation of fetus:
    - fetal movement
    - fetal heart rate tracing – NST
    - U/S for growth
    - BPP
    - Doppler flow studies

## Laboratory Evaluation of Hypertensive Disorders in Pregnancy

- CBC
- PTT, INR, fibrinogen – if abnormal LFTs or bleeding
- ALT, AST
- creatinine, uric acid
- 24 h urine collection for protein or albumin:creatinine ratio
- may consider placental growth factor (PlGF) testing as an early screening test for suspected preeclampsia

## Complications of Hypertensive Disorders in Pregnancy

- maternal
    - liver and renal dysfunction
    - seizure - "eclampsia"
    - abruptio placentae
    - left ventricular failure/pulmonary edema
    - DIC (release of placental thromboplastin consumptive coagulopathy)
    - HELLP syndrome
    - hemorrhagic stroke (50% of deaths)
- fetal (2° to placental insufficiency)
    - IUGR, prematurity, abruptio placentae, IUFD

## Management of HTN

- for non-severe HTN (149-159/90-105) target a BP of 130-155/80-105 in women without comorbidities or <140/90 in women with comorbidities
- for both pre-existing and gestational HTN, labetalol 100-400 mg PO bid-tid, nifedipine XL preparation 20-60 mg PO od, or α-methyldopa 250-500 mg PO bid-qid
- for severe HTN (BP>160/110), give one of:
    - labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
    - nifedipine 5-10 mg capsule q30min
        - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/h IV, to a maximum of 20 mg IV (or 30 mg IM)
- no ACEI, ARBs, diuretics (in cases of pulmonary edema or cardiac failure, may be used), prazosin, or atenolol
- pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk, then decide to induce shortly thereafter

## Management of Preeclampsia

- if stable and no adverse factors (GA 24-33+6 wk), expectant management, ± delivery as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
- antenatal corticosteroids should be considered if GA ≤ 34 wk
- if >37 wk, immediate delivery is recommended
- for severe preeclampsia, stabilize and deliver, regardless of GA
- if severe preeclampsia during labour, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
- antihypertensive therapy
    - labetalol 20 mg IV, then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
    - nifedipine 5-10 mg capsule q30min
        - hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5-10 mg/h IV, to a maximum of 20 mg IV (or 30 mg IM)

**I-A Evidence-Recommendation Highlights of SOGC Clinical Practice Guidelines Diagnosis, Evaluation, and Management of the Hypertensive Disorders of Pregnancy**
J Obstet Gynaecol Can 2014;36(5):416-38

- For BP measurement, Korotkoff phase V should be used to designate the dBP.
- Calcium supplementation (of at least 1g/d, orally) is recommended for women with low dietary intake of calcium (<600 mg/d). (I-A)
- For preeclampsia prevention among increased risk women, low-dose ASA (75-100 mg/d) is recommended until delivery.
- Umbilical artery Doppler velocimetry should be part of the antenatal fetal surveillance in preeclampsia.
- Initial antihypertensive therapy for severe HTN (sBP >160 or dBP ≥110) should be with labetalol, nifedipine, or hydralazine.
- Initial antihypertensive therapy for non-severe HTN (BP 140-159/90-109 mmHg) should be with methyldopa, β-blockers, or calcium channel blockers.
- Antenatal corticosteroids for fetal lung maturation should be considered for all women with preeclampsia before 34 wk gestation.
- In a planned vaginal delivery with an unfavourable cervix, cervical ripening should be used.
- Oxytocin 5 units IV or 10 units IM should be used as part of the management during the third stage of labour, particularly in the presence of thrombocytopenia or coagulopathy.
- Magnesium sulfate is the recommended first-line treatment for eclampsia.
- Magnesium sulfate is the recommended eclampsia prophylaxis in severe preeclampsia.

**Preeclampsia Investigations**

- CBC
- AST, ALT
- INR and aPTT (if abn LFTs or bleeding)
- Cr
- Urine (24 h protein collection or albumin/creatinine ratio)
- Uric acid

- seizure prevention
  - magnesium sulfate: 4 g IV loading dose, followed by 1g/h
  - postpartum management
  - risk of seizure highest in first 24 h postpartum – continue $MgSO_4$ for 12-24 h after delivery
  - vitals q1h
  - consider HELLP syndrome
  - most return to a normotensive BP within 2 wk

### Management of Eclampsia

- ABCs
- roll patient into LLDP
- supplemental $O_2$ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
- aggressive antihypertensive therapy for sustained dBP ≥105 mmHg or sBP ≥160 mmHg with hydralazine or labetalol
- prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
- $MgSO_4$ is now the drug of choice
- the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
- mode of delivery is dependent on clinical situation and fetal-maternal condition

**HELLP Syndrome**
**H**emolysis
**E**levated **L**iver Enzymes
**L**ow Platelets

**Differential Diagnosis of Cause for Seizure in a Pregnant Woman**
- Stroke
- Hypertensive disease (hypertensive encephalopathy, pheochromocytoma)
- Space-occupying lesion of the CNS
- Metabolic disorders (hypoglycemia, SIADH)
- Infection (meningitis, encephalitis)
- TTP or thrombophilia
- Idiopathic epilepsy
- Use of illicit drugs
- Cerebral vasculitis

# Medical Complications of Pregnancy

## Iron and Folate Deficiency Anemia

**Table 13. Iron Deficiency and Folate Deficiency Anemia**

| | Iron Deficiency Anemia | Folate Deficiency Anemia |
|---|---|---|
| **Etiology** | See Hematology, H15 | See Hematology, H25 |
| **Epidemiology** | Responsible for 80% of non-physiologic anemia during pregnancy | Incidence varies from 0.5-25% depending on region, population, and diet |
| **Clinical Features** | See Hematology, H15 | See Hematology, H25 |
| **Investigations** | See Hematology, H15 | See Hematology, H25 |
| **Management** | Prevention (non-anemic): 30 mg elemental iron/d (met by most prenatal vitamins)<br>Treatment (anemic): 30-120 mg elemental iron/d<br>325 mg ferrous fumarate = 106 mg elemental Fe; 325 mg ferrous sulfate = 65 mg elemental Fe; 325 mg ferrous gluconate = 36 mg elemental Fe<br>Polysaccharide-Iron Complex = 150 mg elemental Fe/capsule | Prevention: 0.4-1 mg folic acid PO daily for 1-3 mo preconceptually and throughout T1, or 5 mg folic acid/d with past history of ONTD, DM, or antiepileptic medication use |
| **Complications** | Maternal: angina, CHF, infection, slower recuperation, preterm labour<br>Fetal: decreased oxygen carrying capacity leading to fetal distress, IUGR, and low birth weight | Maternal: decreased blood volume, N/V, and anorexia<br>Fetal: neural tube defects in T1, low birth weight, and prematurity |
| **Notes** | Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake<br>Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg), and losses (200 mg) – more needed for multiple gestations | Minimum daily requirement is 0.4 mg<br>Most often associated with iron deficiency anemia<br>Folic acid is necessary for closure of neural tube during early fetal development (by day 28 of gestation) |

## Diabetes Mellitus

### Epidemiology

- 2-4% of pregnancies are complicated by DM

### Classification of Diabetes Mellitus

- type 1 and type 2 DM (see Endocrinology, E7)
- GDM: onset of DM during pregnancy (usually tested for around 24-28 wk GA)

### Etiology

- type 1 and type 2 DM
- GDM: anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → leading to GDM and/or exacerbating pre-existing DM

## MANAGEMENT

### A. TYPE 1 and TYPE 2 DM

#### Preconception
- pre-plan and refer to high-risk clinic
- commence folic acid 3 mo prior
- optimize glycemic control (HbA1c <6%)
- counsel patient on potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, and CAD

#### Pregnancy
- for Type 2 DM, if already on oral medication, generally switch to insulin therapy
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral anti-hyperglycemics
- tight glycemic control
  - insulin dosage may need to be adjusted in T2 due to increased demand and increased insulin resistance
- monitor as for normal pregnancy, plus initial 24 h urine protein and creatinine clearance, retinal exam, and HbA1c
  - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
- increased fetal surveillance (fetal growth, BPP, NST) starting in the late T2 and T3, consider fetal ECHO in the T2 (if high HbA1c in T1 or just prior to pregnancy) to look for cardiac abnormalities

**Monitoring Glucose Levels**
- Frequent measurements of blood glucose during pregnancy are advised for women with type 1 or 2 DM to help prevent or treat both hypoglycemia and hyperglycemia, and also improves neonatal outcome
- Aim for:
  - FPG ≤5.3 mmol/L (95 mg/dL)
  - 1 h post prandial PG ≤7.8 mmol/L (140 mg/dL), 2 h post prandial PG ≤6.7 mmol/L (120 mg/dL)
- Most women can be followed with monthly HbA1c determinations

#### Labour
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose)
- induce by 38-39 wk, depending on glycemic control and presence of end-organ involvment
- type of delivery
  - increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4000 g (8.8 lbs)
  - consider elective C/S for predicted birthweight >4500 g (9.9 lbs) (controversial)
- monitoring
  - during labour, monitor blood glucose q1h with patient on insulin and dextrose drip
  - aim for blood glucose between 3.9-7 mmol/L to reduce the risk of neonatal hypoglycemia

Post-prandial blood glucose values seem to be the most effective at determining the likelihood of macrosomia or other adverse pregnancy outcomes

#### Postpartum
- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

### B. GESTATIONAL DM

#### Screening and Diagnosis
- all pregnant women between 24-28 wk GA (or at any stage if high risk)
- 2 screening options
  - 2-step screening (recommended by the Canadian Diabetes Association)
    - Step 1: perform a random non-fasting 50 g OGCT
      - 1 h PG <7.8 mmol/L is normal
      - 1 h PG ≥11.1 mmol/L is GDM
      - if 1 h PG 7.8-11.0 mmol/L, proceed to Step 2
    - Step 2: perform a fasting 75 g OGTT, GDM if ≥1 of:
      - FPG ≥5.3 mmol/L
      - 1 h PG ≥10.6 mmol/L
      - 2 h PG ≥9.0 mmol/L
  - Alternative 1-step screening with fasting 75 g OGTT; GDM if ≥1 of:
    - FPG ≥5.1 mmol/L
    - 1 h PG ≥10.0 mmol/L
    - 2 h PG ≥8.5 mmol/L

**Risk Factors for GDM**
- Age >25 yr
- Obesity
- Ethnicity (Aboriginal, Hispanic, Asian, and African)
- FHx of DM
- Previous history of GDM
- Previous child with birthweight >4.0 kg
- Polycystic ovarian syndrome
- Current use of glucocorticoids
- Essential HTN or pregnancy-related HTN

#### Management
- first line: diet modification and increased physical activity
- initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
- glycemic targets: FPG <5.3 mmol/L, 1 h PG <7.8 mmol/L, 2 h PG <6.7 mmol/L
- oral agents can be used in pregnancy but is off-label and should be discussed with patient
- stop insulin and diabetic diet postpartum
- follow-up with 75 g OGTT between 6 wk-6 mo postpartum, counsel about lifestyle modifications

#### Prognosis
- most maternal and fetal complications are related to hyperglycemia and its effects

**Table 14. Complications of DM in Pregnancy**

| Maternal | Fetal |
|---|---|
| **Obstetric**<br>HTN/preeclampsia (especially if pre-existing nephropathy/proteinuria): insulin resistance is implicated in etiology of HTN<br>Polyhydramnios: maternal hyperglycemia leads to fetal hyperglycemia, which leads to fetal polyuria (a major source of amniotic fluid) | **Growth Abnormalities**<br>Macrosomia: maternal hyperglycemia leads to fetal hyperinsulinism resulting in accelerated anabolism<br>IUGR: due to placental vascular insufficiency |
| **Diabetic Emergencies**<br>Hypoglycemia<br>Ketoacidosis<br>Diabetic coma | **Delayed Organ Maturity**<br>Fetal lung immaturity: hyperglycemia interferes with surfactant synthesis (respiratory distress syndrome) |
| **End-Organ Involvement or Deterioration (occur in type 1 DM and type 2 DM, not in GDM)**<br>Retinopathy<br>Nephropathy | **Congenital Anomalies (occur in type 1 DM and type 2 DM, not in GDM)**<br>2-7x increased risk of cardiac (ventricular septal defect), NTD, GU (cystic kidneys), GI (anal atresia), and MSK (sacral agenesis) anomalies due to hyperglycemia<br>Note: Pregnancies complicated by GDM do not manifest an increased risk of congenital anomalies because GDM develops after the critical period of organogenesis (in T1) |
| **Other**<br>Pyelonephritis/UTI: glucosuria provides a culture medium for *E. coli* and other bacteria<br>Increased incidence of spontaneous abortion (in type 1 DM and type 2 DM, not in GDM): related to pre-conception glycemic control | **Labour and Delivery**<br>Preterm labour/prematurity: most commonly in patients with HTN/preeclampsia<br>Preterm labour is associated with poor glycemic control but the exact mechanism is unknown<br>Increased incidence of stillbirth<br>Birth trauma: due to macrosomia, can lead to difficult vaginal delivery and shoulder dystocia<br><br>**Neonatal**<br>Hypoglycemia: due to pancreatic hyperplasia and excess insulin secretion in the neonate<br>Hyperbilirubinemia and jaundice: due to prematurity and polycythemia<br>Hypocalcemia: exact pathophysiology not understood, may be related to functional hypoparathyroidism<br>Polycythemia: hyperglycemia stimulates fetal erythropoietin production |

### Long-Term Maternal Complications
- type 1 and type 2 DM: risk of progressive retinopathy and nephropathy
- GDM: 50% risk of developing type 2 DM in next 20 yr

## Early-Onset Group B *Streptococcus*

### Epidemiology
- 15-40% recto-vaginal carrier rate

### Risk Factors (for neonatal disease)
- maternal intrapartum GBS colonization during current pregnancy
- GBS bacteria at any time during the current pregnancy
- previous infant with invasive GBS disease
- prolonged rupture of membranes ≥18 h
- maternal fever (temperature ≥38°C)

### Clinical Features
- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

### Investigations
- offer screening to all women at 35-37 wk with vaginal and anorectal swabs for GBS culture

### Treatment
- prophylactic treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- indications for antibiotic prophylaxis: positive GBS screen, GBS in urine, previous infant with GBS disease, or GBS status unknown + one of the other risk factors
- antibiotics for GBS prophylaxis (should be given 4 h prior to delivery to be considered adequate)
  - penicillin G, 5 million IU IV, then 2.5 million IU IV q4h until delivery
  - penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
  - penicillin allergic and at risk of anaphylaxis: vancomycin 1 g IV q12h until delivery (vancomycin and clindamycin levels in amniotic fluid do not reach therapeutic levels, all babies should be screened for GBS despite treatment)
- if maternal fever, broad spectrum antibiotic coverage is advised

**Indications for Intrapartum Antibiotic GBS Prophylaxis**
Centres for Disease Control and Prevention. Prevention of Perinatal Group B Streptococcal Disease. MMWR 2010;59(RR-10):14
- Previous infant with invasive GBS disease
- GBS bacteriuria during any trimester of the current pregnancy
- Positive GBS vaginal-rectal screening culture in late gestation during current pregnancy
- Unknown GBS status at the onset of labour (culture not done, incomplete, or results unknown) and any of the following:
  - Delivery at <37 wk gestation
  - Amniotic membrane rupture ≥18 h
  - Intrapartum temperature ≥38.0 °C (≥100.4 °F)
  - Intrapartum nucleic-acid amplification test positive for GBS

# Urinary Tract Infection

## Epidemiology
- most common medical complication of pregnancy
- asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
- note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis and preterm labour

Treat asymptomatic bacteriuria in pregnancy because of increased risk of progression to cystitis, pyelonephritis, and probable increased risk of preterm labour

## Etiology
- increased urinary stasis from mechanical and hormonal (progesterone) factors
- organisms include GBS as well as those that occur in non-pregnant women

## Clinical Features
- may be asymptomatic
- dysuria, urgency, and frequency in cystitis
- fever, flank pain, and costovertebral angle tenderness in pyelonephritis

## Investigations
- urinalysis, urine C&S
- cystoscopy and renal function tests in recurrent infections

## Management
- uncomplicated UTI
  - first line: amoxicillin (250-500 mg PO q8h x 7 d)
  - alternatives: nitrofurantoin (100 mg PO bid x 7 d) or cephalosporins
  - follow with monthly urine cultures
- pyelonephritis
  - hospitalization and IV antibiotics

## Prognosis
- complications if untreated: acute cystitis, pyelonephritis, and possible preterm labour
- recurrence is common

# Infections During Pregnancy

**Table 15. Infections During Pregnancy**

| Infection | Agent | Source of Transmission | Greatest Transmission Risk to Fetus | Effects on Fetus | Effects on Mother | Diagnosis | Management |
|---|---|---|---|---|---|---|---|
| **Chicken Pox** | Varicella zoster virus (herpes family) | To mother: direct, respiratory<br>To baby: transplacental | 13-30 wk GA, and 5 d pre- to 2 d post-delivery | Congenital varicella syndrome (limb aplasia, chorioretinitis, cataracts, cutaneous scars, cortical atrophy, IUGR, hydrops), preterm labour | Fever, malaise, vesicular pruritic lesions | Clinical, ± vesicle fluid culture, ± serology | Varicella-zoster immune globulin for mother if exposed, decreases congenital varicella syndrome<br>Note: do not administer vaccine during pregnancy (live attenuated vaccine) |
| ***Cytomegalovirus** | DNA virus (herpes family) | To mother: blood/ organ transfusion, sexual contact<br>To baby: transplacental, during delivery, breast milk | T1-T3 | 5-10% develop CNS involvement (mental retardation, cerebral calcification, hydrocephalus, microcephaly, deafness, chorioretinitis) | Asymptomatic or flu-like | Serologic screen; isolate virus from urine or secretion culture | No specific treatment; maintain good hygiene and avoid high risk situations |
| **Erythema Infectiosum (Fifth Disease)** | Parvovirus B19 | To mother: respiratory, infected blood products<br>To baby: transplacental | 10-20 wk GA | Spontaneous abortion (SA), stillbirth, hydrops *in utero* | Flu-like, rash, arthritis; often asymptomatic | Serology, viral PCR, maternal AFP; if IgM present, follow fetus with U/S for hydrops | If hydrops occurs, consider fetal transfusion |
| **Hepatitis B** | DNA virus | To mother: blood, saliva, semen, vaginal secretions<br>To baby: transplacental, breast milk | T3<br>10% vertical transmission if asymptomatic and HBsAg +ve; 85-90% if HBsAg and HBeAg +ve | Prematurity, low birth weight, neonatal death | Fever, N/V, fatigue, jaundice, elevated liver enzymes | Serologic screening for all pregnancies | Rx neonate with HBIG and vaccine (at birth, 1, 6 mo); 90% effective |
| ***Herpes Simplex Virus** | DNA virus | To mother: intimate mucocutaneous contact<br>To baby: transplacental, during delivery | Delivery (if genital lesions present); less commonly *in utero* | Disseminated herpes (20%); CNS sequelae (35%); self-limited infection | Painful vesicular lesions | Clinical diagnosis | Acyclovir for symptomatic women, suppressive therapy at 36 wk controversial<br>Suggested C/S if active genital lesions, even if remote from vulva |

**Table 15. Infections During Pregnancy** (continued)

| Infection | Agent | Source of Transmission | Greatest Transmission Risk to Fetus | Effects on Fetus | Effects on Mother | Diagnosis | Management |
|---|---|---|---|---|---|---|---|
| **HIV** | RNA retrovirus | To mother: blood, semen, vaginal secretions<br>To baby: in utero, during delivery, breast milk | 1/3 *in utero*, 1/3 at delivery, 1/3 breastfeeding | IUGR, preterm labour, PROM | See Infectious Diseases, ID25 | Serology, viral PCR<br>All pregnant women are offered screening | Triple anti-retroviral therapy decreases transmission to <1%<br>Elective C/S: no previous antiviral Rx or monotherapy only, viral load unknown or >500 RNA copies/mL, unknown prenatal care, patient request |
| ***Rubella** | ssRNA togavirus | To mother: respiratory droplets (highly contagious)<br>To baby: transplacental | T1 | SA or congenital rubella syndrome (hearing loss, cataracts, CV lesions, mitral regurgitation, IUGR, hepatitis, CNS defects, osseous changes) | Rash (50%), fever, posterior auricular or occipital lymphadenopathy, arthralgia | Serologic testing; all pregnant women screened (immune if titre >1:16); infection if IgM present or >4x increase in IgG | No specific treatment; offer vaccine following pregnancy<br>Do not administer during pregnancy (live attenuated) |
| **Syphilis** | Spirochete (*Treponema pallidum*) | To mother: sexual contact<br>To baby: transplacental | T1-T3 | Risk of preterm labour, multisystem involvement, fetal death | See Infectious Diseases, ID23 | VDRL screening for all pregnancies; if positive, requires confirmatory testing | Penicillin G 2.4 million IU IM x 1 dose if early syphilis, 3 doses if late syphilis, monitor VDRL monthly<br>If penicillin G allergic: clindamycin 900 mg IV q8h |
| ***Toxoplasmosis** | Protozoa (*Toxoplasma gondii*) | To mother: raw meat, unpasteurized goat's milk, cat feces/urine<br>To baby: transplacental | T3 (but most severe if infected in T1); only concern if primary infection during pregnancy | Congenital toxoplasmosis (chorioretinitis, hydrocephaly, intracranial calcification, mitral regurgitation, microcephaly) NB: 75% initially asymptomatic at birth | Majority subclinical; may have flu-like symptoms | IgM and IgG serology; PCR of amniotic fluid | Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission |

* Indicates TORCH infection

# Venous Thromboembolism

## Epidemiology

- incidence of 12.1/10,000 (DVT), and 5.4/10,000 (PE)
- increased risk of VTE throughout pregnancy with highest risk of DVT in T3 and post-partum period; highest risk of PE post-partum (first 6 wk)

## Risk Factors

- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, and thrombophilias (see Hematology, H35)

**Table 16. Risk Factors for VTE Specific to Pregnancy**

| Hypercoagulability | Stasis | Endothelial |
|---|---|---|
| Increased Factors:<br>II, V, VII, VIII, IX, X, XII, fibrinogen<br>Increased platelet aggregation<br>Decreased protein S, tPA, factors XI, XIII<br>Increased resistance to activated protein C<br>Antithrombin can be normal or reduced | Increased venous distensibility<br>Decreased venous tone<br>50% decrease in venous flow in lower extremity by T3<br>Uterus is mechanical impediment to venous return | Vascular damage at delivery (C/S or SVD)<br>Uterine instrumentation<br>Peripartum pelvic surgery |

**Virchow's Triad for VTE**
- Hypercoagulable state
- Stasis
- Endothelial damage

## Clinical Features

- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific

## Investigations

- duplex venous Doppler sonography for DVT
- CXR and V/Q scan or spiral CT for PE

## Management

- before initiating treatment, obtain a baseline CBC including platelets and aPTT
- treatment with LMWH preferred
  - dosing varies depending on specific LMWH used
  - should be discontinued at least 24 h prior to delivery

- unfractionated heparin
  - bolus of 5000 IU followed by an infusion of ~30,000 IU/24h
  - measure aPTT 6 h after the bolus
  - maintain aPTT at a therapeutic level (1.5-2x normal)
  - repeat q24h once therapeutic
  - heparin-induced thrombocytopenia (HIT) uncommon (3%), but serious complication
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- compression stockings
- poor evidence to support a recommendation for or against avoidance of prolonged sitting
- VTE prophylaxis
  - women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
  - women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
  - insufficient evidence in pregnancy to recommend routine use of LMWH for all patients
  - current prophylaxis regimens for acquired thrombophilias (e.g. APS) include low dose ASA in conjunction with prophylactic heparin

# Normal Labour and Delivery

## Definition of Labour

- true labour: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
  - preterm (≥20 to ≤36+6 wk GA)
  - term (37-41+6 wk GA)
  - postterm (≥42 wk GA)
- false labour (Braxton-Hicks contractions): irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any cervical dilatation, effacement, or descent
  - often relieved by rest or sedation

## The Cervix

- see Bishop Score (see Table 21, OB37)
  - dilatation: latent phase (0-4 cm, variable time); active phase (4-10 cm)
  - effacement: thinning of the cervix by percentage or length of cervix (cm)
  - consistency: firm, medium, or soft
  - position: posterior, mid, or anterior
- other consideration:
  - application: contact between the cervix and presenting part (i.e. well or poorly applied)

## The Fetus

- **fetal lie**: orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, and oblique)
- **fetal presentation**: fetal body part closest to the birth canal
  - breech (complete, frank, and incomplete) (see Figure 5, OB23)
  - cephalic (vertex/occiput, face, or brow)
  - transverse (shoulder)
  - compound (fetal extremity prolapses along with presenting part)
  - all except vertex are considered malpresentations (see *Obstetrical Complications*, OB16)
- **fetal position**: position of presenting part of the fetus relative to the maternal pelvis
  - OA: most common presentation ("normal") – left OA most common
  - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour
  - OT: leads to arrest of dilatation
    - normally, fetal head enters maternal pelvis and engages in OT position
    - subsequently rotates to OA position (or OP in a small percentage of cases)
- **attitude**: flexion/extension of fetal head relative to shoulders
  - brow presentation: head partially extended (requires C/S)
  - face presentation: head fully extended
    - mentum posterior always requires C/S, mentum anterior can deliver vaginally
- **station**: position of presenting bony part relative to ischial spines – determined by vaginal exam
  - at ischial spines = station 0 = engaged
  - –5 to –1 cm above ischial spines
  - +1 to +5 cm below ischial spines
- **asynclitism**: alignment of the sagittal suture relative to the axis of the birth canal
  - lateral tilt seen with either anterior or posterior asynclitism and may impact descent

**Maternal Triage Assessment**
**ID**: Age, GPA, EDD, GA, GBS, Rh, Serology
**CC**
**HPI**: 4 key questions:
- Contractions: Since when, how close (q x min), how long (x s), how painful
- Bleeding: Since when, how much (pads), colour (pinky vs. brownish vs. bright red), pain, last U/S, trauma/intercourse
- Fluid (ROM): Since when, large gush vs. trickle, soaked pants, clear vs. green vs. red, continuous
- FM: As much as usual?, When last movement?, Kick counts (lie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

**PregHx**: Any complications (HTN, GDM, infections), IPS/FTS screening, last U/S (BPP score, growth/estimated fetal weight, position), last vaginal exam
**POBHx**: Every previous pregnancy and outcome: year, SVD/C-section/miscarriage/abortion, baby size, length of labour, use of vacuum or forceps, complications
**PMHx, Meds, Allergies, SHx**
**O/E**: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold's, vaginal exam, U/S

**Reference Point for Describing Fetal Position**
- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation

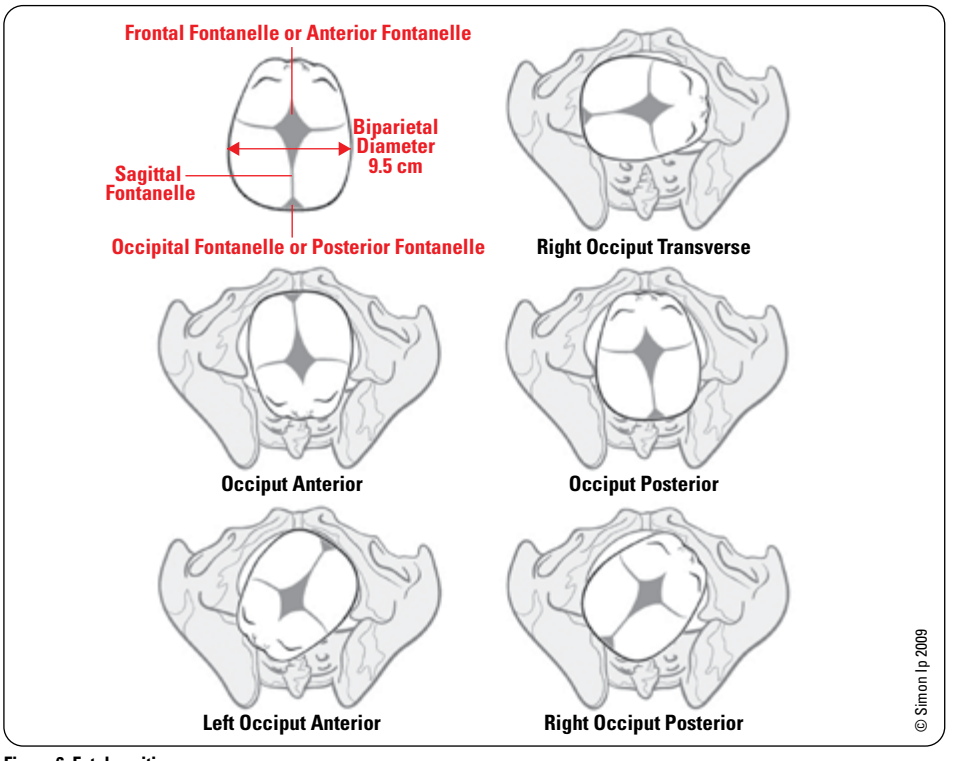

**Figure 6. Fetal positions**

# Four Stages of Labour

## First Stage of Labour (0 – 10 cm cervical dilation)

- latent phase
  - uterine contractions typically infrequent and irregular
  - slow cervical dilatation (usually to 4 cm) and effacement
- active phase
  - rapid cervical dilatation to full dilatation (nulliparous ≥1.0 cm/h, multiparous ≥1.2 cm/h)
  - phase of maximum slope on cervical dilatation curve
  - painful, regular contractions q2-3min, lasting 45-60 s
  - contractions strongest at fundus

## Second Stage of Labour (10 cm dilation – delivery of the baby)

- from full dilatation to delivery of the baby; duration varies based on parity, contraction quality, and type of analgesia
- mother feels a desire to bear down and push with each contraction
- women may choose a comfortable position that enhances pushing efforts and delivery
  - upright (semi-sitting, squatting) and LLDP are supported in the literature
- progress measured by descent

## Third Stage of Labour (delivery of the baby – delivery of the placenta)

- from baby's birth to separation and expulsion of the placenta
- can last up to 30 min before intervention is indicated
- demonstrated by gush of fresh blood, umbilical cord lengthening, uterine fundus changing shape (firm and globular), and rising upward
- active management: start oxytocin IV drip, or give 10 IU IM or 5 mg IV push, after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
- routine oxytocin administration in third stage of labour can reduce the risk of PPH by >40%

## Fourth Stage of Labour

- first postpartum hour
- monitor vital signs and bleeding, repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

**Course of Normal Labour***

| Stage | Nulliparous | Multiparous |
|---|---|---|
| First | 6-18 h | 2-10 h |
| Second | 30 min-3 h | 5-30 min |
| Third | 5-30 min | 5-30 min |

*without epidural

**Signs of Placental Separation**

- Gush of blood
- Lengthening of cord
- Uterus becomes globular
- Fundus rises

**Continuous Support for Women During Childbirth**
Cochrane DB Syst Rev 2011;16:CD003766
**Study**: Systematic review of 21 RCTs from 11 countries, 15,061 women in labour.
**Intervention**: Continuous support during labour vs. usual care.
**Outcome**: Effects on mothers and their babies.
**Results**: Continuous intrapartum support increased likelihood of shorter labour, spontaneous vaginal birth, decrease in analgesia use, and a decrease in dissatisfaction with childbirth experience. Greatest benefit when provider is not a health care professional. Continuous support was also associated with decreased likelihood to have a Cesarean or instrumental vaginal birth, regional analgesia, or a baby with a low 5 min APGAR score.

# The Cardinal Movements of the Fetus During Delivery

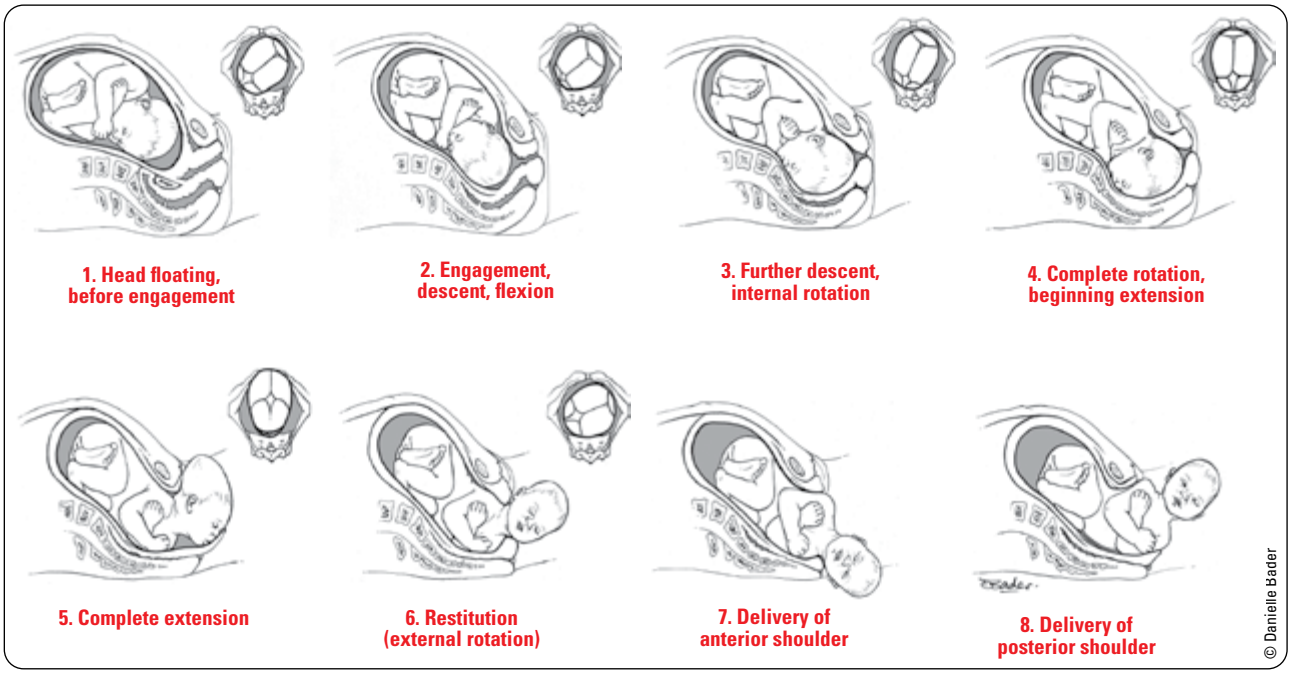

**Figure 7. Cardinal movements of fetus during delivery**
Adapted from illustration in Williams Obstetrics, 19th ed

# Analgesic and Anesthetic Techniques in Labour and Birth

- pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

### Non-Pharmacologic Pain Relief Techniques

- reduction of painful stimuli
  - maternal movement, position change, counter-pressure, and abdominal compression
- activation of peripheral sensory receptors
  - superficial heat and cold
  - immersion in water during labour
  - touch and massage, acupuncture, and acupressure
  - TENS
  - intradermal injection of sterile water
  - aromatherapy
- enhancement of descending inhibitory pathways
  - attention focusing and distraction
  - hypnosis
  - music and audio analgesia
  - biofeedback

### Pharmacologic Methods (see Anesthesia and Perioperative Medicine, A27)

- nitrous oxide (e.g. self-administered Entonox®)
- narcotics (usually combined with anti-emetic)
- pudendal nerve block
- perineal infiltration with local anesthetic
- regional anesthesia (epidural block, combined spinal-epidural, and spinal)

# Fetal Monitoring in Labour

- see online **Fetal Heart Rate Tutorial**

### Vaginal Exam

- membrane status, as indicated by amniotic fluid (clear, pink, bloody, and meconium)
- cervical effacement (thinning), dilatation, consistency, position, and application
- fetal presenting part, position, and station
- bony pelvis size and shape
- monitor progress of labour at regular intervals and document in a partogram

## Intrapartum Fetal Monitoring

- intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, labour which is induced or augmented, meconium present, multiple gestation/fetal complication, and concerns about the fetus tolerating labour
  - use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate when used routinely in all patients (i.e. no risk factors)
  - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

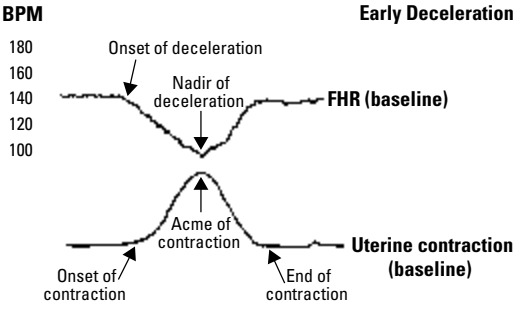
## Electronic FHR Monitoring

- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)
- **Baseline FHR**
  - normal range is 110-160 bpm
  - parameter of fetal well-being vs. distress
- **Variability**
  - physiologic variability is a normal characteristic of FHR
  - variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), or marked (>25 bpm)
  - normal variability indicates fetal acid-base status is acceptable
  - can only be assessed by electronic contraction monitoring (CTG)
  - variability decreases intermittently even in healthy fetus
  - see Table 19, OB35
- **Periodicity**
  - accelerations: increase of ≥15 bpm for ≥15 s, (or ≥10 bpm for ≥10 s if <32 wk GA)
  - decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

**Table 17. Factors Affecting Fetal Heart Rate**

| | Fetal Tachycardia (FHR >160 bpm) | Fetal Bradycardia (FHR <110 bpm) | Decreased Variability |
|---|---|---|---|
| **Maternal Factors** | Fever, hyperthyroidism, anemia, dehydration | Hypothermia, hypotension, hypoglycemia, position, umbilical cord occlusion | Infection<br>Dehydration |
| **Fetal Factors** | Arrhythmia, anemia, infection, prolonged activity, chronic hypoxemia, congenital anomalies | Rapid descent, dysrhythmia, heart block, hyopoxia, vagal stimulation (head compression), hypothermia, acidosis | CNS anomalies<br>Dysrhythmia<br>Inactivity/sleep cycle, preterm fetus |
| **Drugs** | Sympathomimetics | β-blockers<br>Anesthetics | Narcotics, sedatives<br>Magnesium sulphate, β-blockers |
| **Uteroplacental** | Early hypoxia (abruption, HTN)<br>Chorioamnionitis | Late hypoxia (abruption, HTN)<br>Acute cord prolapse<br>Hypercontractility | Hypoxia |

**Approach to the Management of Abnormal FHR**



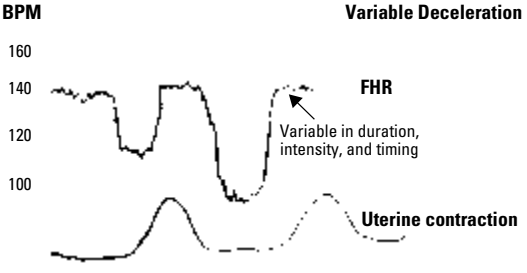
**POISON – ER**
**P**osition (LLDP)
**O**$_2$ (100% by mask)
**I**V fluids (corrects maternal hypotension)
Fetal **s**calp stimulation
Fetal **s**calp electrode
Fetal **s**calp pH
Stop **o**xytocin
**N**otify MD
Vaginal **e**xam to rule out cord prolapse
**R**ule out fever, dehydration, drug effects, prematurity
- If above fails, consider C/S

**Continuous CTG as a Form of EFM for Fetal Assessment During Labour**
Cochrane DB Syst Rev 2013;5:CD006066
**Purpose**: To examine the effectiveness of continuous electronic fetal monitoring or cardiotocography during labour.
**Selection Criteria**: Randomized and quasi-randomized controlled trials comparing continuous CTG (with and without fetal blood sampling) to a) no fetal monitoring, b) intermittent auscultation, or c) intermittent CTG.
**Results**: 13 trials, 37,000 women. Continuous CTG compared with intermittent auscultation showed no difference in overall perinatal death rate or cerebral palsy rates. Nonetheless, neonatal seizures were halved (RR 0.50, 95% CI 0.31-0.80) and there was a significant increase in C/S (RR 1.63, 95% CI 1.29-2.07) and instrumental vaginal birth (RR 1.15, 95% CI 1.01-1.33) with CTG.
**Conclusion**: Continuous CTG may reduce the incidence of neonatal seizures, but has no effect on cerebral palsy rates, infant mortality, or other measures of neonatal well-being. Continuous CTG was also associated with an increase in C/S and instrumental deliveries.

## Table 18. Comparison of Decelerations

### Early Decelerations

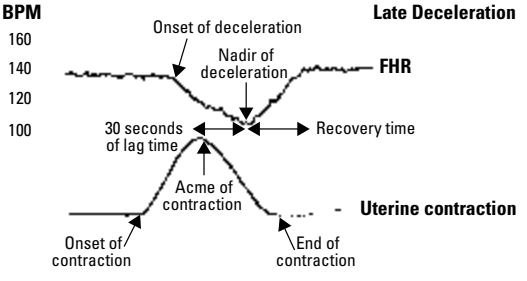
- Uniform shape with onset early in contraction, returns to baseline by end of contraction, mirrors contraction (nadir occurs at peak of contraction)
- Gradual deceleration and return to baseline
- Often repetitive; no effect on baseline FHR or variability
- Benign, due to vagal response to head compression



### Variable Decelerations

- Variable in shape, onset, and duration
- Most common type of periodicity seen during labour
- Often with abrupt drop in FHR >15 bpm below baseline (>15 s, <2 min); usually no effect on baseline FHR or variability
- Due to cord compression or, in second stage, forceful pushing with contractions

### Complicated Variable Decelerations



- FHR drop <70 bpm for >60 s
- Loss of variability or decrease in baseline after deceleration
- Biphasic deceleration
- Slow return to baseline
- Baseline tachycardia or bradycardia
- May be associated with fetal acidemia

**Rule of 60s Suggesting Severe Variable Decelerations**
Deceleration to <60 bpm
>60 bpm below baseline
>60 s in duration with slow return to baseline

### Late Decelerations

- Uniform shape with onset, nadir, and recovery occurring after peak of contraction, slow return to baseline
- May cause decreased variability and change in baseline FHR
- Due to fetal hypoxia and acidemia, maternal hypotension, or uterine hypertonus
- Usually a sign of uteroplacental insufficiency (an ominous sign)

## Table 19. Classification of Intrapartum EFM Tracings

| | Normal Tracing (Category 1) | Atypical Tracing* (Category 2) | Abnormal Tracing* (Category 3) |
|---|---|---|---|
| **Baseline** | 110-160 bpm | Bradycardia 100-110 bpm<br>Tachycardia >160 for 30-80 min<br>Rising baseline | Bradycardia <100 bpm<br>Tachycardia >160 bpm for >80 min<br>Erratic baseline |
| **Variability** | 6-25 bpm<br>≤5 bpm for <40 min | ≤5 bpm for 40-80 min | <5 bpm for >80 min<br>≥25 bpm for >10 min |
| **Decelerations** | None<br>Early decelerations<br>Occasional uncomplicated variable decelerations | Repetitive (≥3) uncomplicated variable decelerations<br>Occasional late decelerations<br>Any prolonged deceleration (2-3 min) | Repetitive (≥3) complicated variable decelerations<br>Repetitive late decelerations<br>Any prolonged deceleration (≥3 min) |
| **Accelerations** | Accelerations spontaneous or during scalp stimulation | Absent with scalp stimulation | Nearly absent |
| **Action** | EFM may be interrupted for ≤30 min if mother/fetus stable | Further assessment required | Action required: review clinical situation, obtain scalp pH, prepare for possible delivery |

Adapted from SOGC Guidelines, September 2008
*Previous classification was "reassuring" vs. "non-reassuring", but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) versus those with major concerns requiring immediate intervention (abnormal)

## Fetal Scalp Blood Sampling

- cervix must be adequately dilated
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns (including unexplained low variability, repetitive late decelerations, complex variable decelerations, and fetal cardiac arrhythmias)

- done by measuring pH or more recently fetal lactate
  - pH ≥7.25, lactate <4.2 mmol/L: normal, repeat if abnormal FHR persists
  - pH 7.21-7.24, lactate 4.2-4.8 mmol/L: repeat assessment in 30 min or consider delivery if rapid fall since last sample
  - pH ≤7.20, lactate >4.8 mmol/L indicates fetal acidosis, delivery is indicated
- contraindications
  - known or suspected fetal blood dyscrasia (hemophilia, vWD)
  - active maternal infection (HIV, genital herpes)

### Fetal Oxygenation

- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
- fetal response to hypoxia/asphyxia:
  - decreased movement, tone, and breathing activities
  - anaerobic metabolism (decreased pH)
  - transient fetal bradycardia followed by fetal tachycardia
  - redistribution of fetal blood flow
- increased flow to brain, heart, and adrenals
- decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
- increase in blood pressure

**Table 20. Factors Affecting Fetal Oxygenation**

| Factor | Mechanism | Example |
|---|---|---|
| **Maternal** | Decreased maternal oxygen carrying capacity | Significant anemia (iron deficiency, hemoglobinopathies), carboxyhemoglobin (smokers) |
| | Decreased uterine blood flow | Hypotension (blood loss, sepsis), regional anesthesia, maternal positioning |
| | Chronic maternal conditions | Vasculopathies (SLE, type 1 DM, chronic HTN), APS, cyanotic heart disease, COPD |
| **Uteroplacental** | Uterine hypertonus | Placental abruption, hyperstimulation secondary to oxytocin, prostaglandins, or normal labour |
| | Uteroplacental dysfunction | Placental abruption, placental infarction (dysfunction marked by IUGR, oligohydramnios, abnormal Doppler studies), chorioamnionitis, placental edema (DM, hydrops), placental senescence (post-dates) |
| **Fetal** | Cord compression | Oligohydramnios, cord prolapse, or entanglement |
| | Decreased fetal oxygen carrying capacity | Significant anemia (isoimmunization, feto-maternal bleed), carboxyhemoglobin (exposure to smokers) |

# Induction of Labour

### Definition

- artificial initiation of labour in a pregnant woman prior to spontaneous initiation to deliver the fetus and placenta

### Prerequisites for Labour Induction

- capability for C/S if necessary
- maternal
  - inducible/ripe cervix: short, thin, soft, anterior cervix with open os
  - if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prepidil®), misoprostol (Cytotec®), or Foley catheter
- fetal
  - normal fetal heart tracing
  - cephalic presentation
  - adequate fetal monitoring available
- likelihood of success determined by Bishop score
  - cervix considered unfavourable if <6
  - cervix favourable if ≥6
  - score of 9-13 associated with high likelihood of vaginal delivery

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labour and delivery

**Table 21. Bishop Score**

| Cervical Characteristic | 0 | 1 | 2 | 3 |
|---|---|---|---|---|
| **Position** | Posterior | Mid | Anterior | – |
| **Consistency** | Firm | Medium | Soft | – |
| **Effacement (%)** | 0-30 | 40-50 | 60-70 | ≥80 |
| **Dilatation (cm)** | 0 | 1-2 | 3-4 | ≥5 |
| **Station of Fetal Head** | -3 | -2 | -1, 0 | +1, +2, +3 |

**Induction vs. Augmentation**
**Induction** is the artificial initiation of labour
**Augmentation** promotes contractions when spontaneous contractions are inadequate

### Indications
- post-dates pregnancy (generally >41 wk) = most common reason for induction
- maternal factors
  - DM = second most common reason for induction
  - gestational HTN ≥37 wk
  - preeclampsia
  - other maternal medical problems, e.g. renal or lung disease, chronic hypertension, and cholestasis
  - maternal age over 40
- maternal-fetal factors
  - isoimmunization, PROM, chorioamnionitis
- fetal factors
  - suspected fetal jeopardy as evidenced by biochemical or biophysical indications
  - macrosomia, fetal demise, IUGR, oligo/polyhydramnios, anomalies requiring surgical intervention, and twins
  - previous stillbirth or low PAPP-A

**Consider the Following Before Induction**
- Indication for induction
- Contraindications
- GA
- Cervical favourability
- Fetal presentation
- Potential for CPD
- Fetal well-being/FHR
- Membrane status

### Risks
- failure to achieve labour and/or vaginal birth
- uterine hyperstimulation with fetal compromise or uterine rupture
- maternal side effects to medications
- uterine atony and PPH

### Contraindications
- maternal
  - prior classical or inverted T-incision C/S or uterine surgery (e.g. myomectomy)
  - unstable maternal condition
  - active maternal genital herpes
  - invasive cervical carcinoma
  - pelvic structure deformities
- maternal-fetal
  - placenta previa or vasa previa
  - cord presentation
- fetal
  - fetal distress, malpresentation/abnormal lie, or preterm fetus without lung maturity

## Induction Methods

### CERVICAL RIPENING

### Definition
- use of medications or other means to soften, efface, and dilate the cervix; increases likelihood of successful induction
- ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

### Methods
- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  - recommended dosing interval of prostaglandin gel is every 6-12 h up to 3 doses
- intravaginal PGE2 (Cervidil®): long and closed cervix, may use if ROM
  - continuous release, can be removed if needed
  - controlled release PGE2
- intracervical PGE2 (Prepidil®)
- intravaginal PGE1 misoprostol (Cytotec®): long and closed cervix
  - inexpensive, stored at room temperature
  - more effective than PGE2 for achieving vaginal delivery and less epidural use
- Foley catheter placement to mechanically dilate the cervix

**Evidence for Cervical Ripening Methods (SOGC Guidelines)**
- Meta-analysis of five trials has concluded that the use of oxytocin to ripen the cervix is not effective
- Since the best dose and route of misoprostol for labour induction with a live fetus are not known and there are concerns regarding hyperstimulation, the use of misoprostol for induction of labour should be within clinical trials only (Level Ib evidence) or in cases of intrauterine fetal death to initiate labour

**Intravaginal PGE2 (Cervidil®) Compared to Intravaginal Prostaglandin Gel**
4 RCTs have compared the two with varying results, depending on the dosing regime of gel used.
Theoretical advantages of Cervidil®:
- Slow, continuous release
- Only one dose required
- Ability to use oxytocin 30 min after removal vs. 6 hours for gel
- Ability to remove insert if required (i.e. excessive uterine activity)

## INDUCTION OF LABOUR

### Amniotomy

- artificial ROM (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is open and soft, the membranes can be felt, and if the head is present at the cervix
- few studies address the value of amniotomy alone for induction of labour
- amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

### Oxytocin

- oxytocin (Pitocin®): 10 U in 1L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min
- reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
- ideal dosing regimen of oxytocin is not known
- current recommendations: use the minimum dose to achieve active labour and increase q30min as needed
- reassessment should occur once a dose of 20 mU/min is reached
- potential complications
  - hyperstimulation/tetanic contraction (may cause fetal distress or uterine rupture)
  - uterine muscle fatigue, uterine atony (may result in PPH)
  - vasopressin-like action causing anti-diuresis

Oxytocin t1/2 = 3-5 min

# Augmentation of Labour

- augmentation of labour with oxytocin is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur

Provided there are no contraindications, oxytocin is utilized to improve uterine contraction strength and/or frequency

# Abnormalities and Complications of Labour and Delivery

## Abnormal Progression of Labour (Dystocia)

### Definition

- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour
- during active phase: >4 h of <0.5 cm/h
- during 2nd stage: >1 h with no descent during active pushing

### Etiology

- Power (leading cause): contractions (hypotonic, uncoordinated), inadequate maternal expulsive efforts
- Passenger: fetal position, attitude, size, anomalies (hydrocephalus)
- Passage: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- Psyche: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

**The 4 Ps of Dystocia**
**P**ower
**P**assenger
**P**assage
**P**syche

### Management

- confirm diagnosis of labour (rule out false labour)
- search for factors of CPD
- concern for dystocia if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
- management: if CPD ruled out, IV oxytocin augmentation ± amniotomy

### Risks of Dystocia

- inadequate progression of labour is associated with an increased incidence of:
  - maternal stress
  - maternal infection
  - PPH
  - need for neonatal resuscitation
  - fetal compromise (from uterine hyperstimulation)
  - uterine rupture
  - hypotension

# Shoulder Dystocia

### Definition
- fetal anterior shoulder impacted above pubic symphysis after fetal head has been delivered
- life threatening emergency

### Etiology/Epidemiology
- incidence 0.15-1.4% of deliveries
- occurs when breadth of shoulders is greater than biparietal diameter of the head

### Risk Factors
- maternal: obesity, DM, multiparity, and previous shoulder dystocia
- fetal: prolonged gestation or macrosomia (especially if associated with GDM)
- labour
  - prolonged 2nd stage
  - instrumental midpelvic delivery

### Presentation
- "turtle sign": head delivered but retracts against inferior portion of pubic symphysis
- complications
  - fetal
    - hypoxic ischemic encephalopathy (chest compression by vagina or cord compression by pelvis can lead to hypoxia)
    - brachial plexus injury (Erb's palsy: C5-C7; Klumpke's palsy: C8-T1), 90% resolve within 6 mo
    - fracture (clavicle, humerus, and cervical spine)
    - death
  - maternal
    - perineal injury
    - PPH (uterine atony or lacerations)
    - uterine rupture

### Treatment
- goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved (see sidebar)
- other options
  - cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
  - symphysiotomy

### Prognosis
- 1% risk of long-term disability for infant

**Approach to the Management of Shoulder Dystocia**

**ALARMER**
**A**pply suprapubic pressure and ask for help
**L**egs in full flexion (McRobert's maneuver)
**A**nterior shoulder disimpaction (suprapubic pressure)
**R**elease posterior shoulder by rotating it anteriorly with hand in the vagina under adequate anesthesia
**M**anual corkscrew i.e. rotate the fetus by the posterior shoulder until the anterior shoulder emerges from behind the maternal symphysis
**E**pisiotomy
**R**ollover (on hands and knees)
*Note that suprapubic pressure and McRobert's maneuver together will resolve 90% of cases

# Umbilical Cord Prolapse

### Definition
- descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

### Etiology/Epidemiology
- increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, and CPD
- incidence: 1/200-1/400 deliveries

### Presentation
- visible or palpable cord
- FHR changes (variable decelerations, bradycardia, or both)

### Treatment
- emergency C/S if not fully dilated and vaginal delivery not imminent
- $O_2$ to mother, monitor fetal heart
- alleviate pressure of the presenting part on the cord by elevating fetal head with a pelvic exam (maintain this position until C/S)
- keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
- roll mother onto all fours or position mother in Trendelenburg or knee-to-chest position
- if fetal demise or too premature (<22 wk), allow labour and delivery

**Umbilical Cord Accident Causes**
- Nuchal cord
  - Type A (looped)
  - Type B (hitched)
- Body loop
- Single artery
- True knot
- Torsion
- Velamentous
- Short cord <35 cm
- Long cord >80 cm

- 1/3 of protraction disorders develop into 2° arrest of dilatation due to CPD
- 2/3 of protraction disorders progress through labour to vaginal delivery

# Uterine Rupture

### Definition
- associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity, and previous intrauterine manipulation
- generally occurs during labour, but can occur earlier with a classical incision
- 0.5-0.8% incidence, up to 12% with classical incision

### Presentation
- prolonged fetal bradycardia – most common presentation
- acute onset of constant lower abdominal pain, may not have pain if receiving epidural analgesia
- hyper/hypotonic uterine contractions
- abnormal progress in labour
- vaginal bleeding
- intra-abdominal hemorrhage
- loss of station of the presenting fetal part
- maternal tachycardia, hypotension, or shock

### Risk Factors
- uterine scarring (i.e. previous uterine surgeries including C/S (especially classical incision), perforation with D&C, and myomectomy)
- excessive uterine stimulation (i.e. protracted labour, oxytocin, prostaglandins)
- uterine trauma (i.e. operative equipment, ECV)
- multiparity
- uterine abnormalities
- malpresentation
- placenta accreta

### Treatment
- rule out placental abruption
- maternal stabilization (may require hysterectomy), treat hypovolemia
- immediate delivery for fetal survival

### Complications
- maternal mortality 1-10%
- maternal hemorrhage, shock, DIC
- amniotic fluid embolus
- hysterectomy if uncontrollable hemorrhage
- fetal distress, associated with infant mortality as high as 15%

**Maternal Mortality Causes**
- Thromboembolism
- Cardiac event
- Suicide
- Sepsis
- Ectopic pregnancy
- HTN
- Amniotic fluid embolism
- Hemorrhage

* In Canada (2013), lifetime risk of maternal death is 1 in 5200

# Amniotic Fluid Embolus

### Definition
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

### Etiology/Epidemiology
- rare intrapartum or immediate postpartum complication
- 13-30% maternal mortality rate
- leading cause of maternal death in induced abortions and miscarriages
- 1/8000-1/80,000 births

### Risk Factors
- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation
- induction medication and procedures

### Differential Diagnosis
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, and chronic coagulopathy

### Presentation
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

### Management
- should be managed in the ICU by a multidisciplinary team
- supportive measures (high flow $O_2$, ventilation support, fluid resuscitation, inotropic support, ± intubation) and coagulopathy correction

## Chorioamnionitis

### Definition
- infection of the chorion, amnion, and amniotic fluid

### Etiology/Epidemiology
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending infection (microorganisms from vagina)
- predominant microorganisms include: GBS, *Bacteroides* and *Prevotella* species, *E. coli*, and anaerobic *Streptococcus*

**Clinical Features of Chorioamnionitis**
- Temperature
- Tachycardia (maternal or fetal)
- Tenderness (uterine)
- Foul discharge

### Risk Factors
- low parity, prolonged ROM, long labour, multiple vaginal exams during labour, and internal monitoring
- bacterial vaginosis and other vaginal infections

### Clinical Features
- maternal fever ≥38° C, maternal or fetal tachycardia, uterine tenderness, and foul and purulent cervical discharge

### Investigations
- CBC: leukocytosis
- amniotic fluid: Gram stain, glucose, or culture results consistent with infection

### Treatment
- IV antibiotics
  - ampicillin 2 g IV q6h + gentamicin 2 mg/kg load, then 1.5 mg/kg IV q8h
  - anaerobic coverage (i.e. clindamycin 900 mg IV q8h)
  - if at risk for endometritis, continue treatment post-partum especially if C/S delivery
- antipyretics
- proper labour progression (not an indication for immediate delivery or C/S)

### Complications
- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, neonatal meningitis, neonatal sepsis, and neonatal death
- long-term infant complications: cerebral palsy and bronchopulmonary dysplasia

## Meconium

### Epidemiology
- present early in labour in 10% of pregnancies, more common in postdate pregnancies
- in general, meconium may be present in up to 25% of all labours; usually NOT associated with poor outcome
- concern if fluid changes from clear to meconium-stained
- always abnormal if seen in preterm fetus

Particulate (thickened) meconium is associated with lower APGARs, an increased risk of meconium aspiration, and perinatal death. Particulate meconium generally has a darker green or black colour, whereas thin meconium is usually yellow to light green

### Etiology
- likely cord compression ± uterine hypertonia
- may indicate undiagnosed breech
- increasing meconium during labour may be a sign of fetal distress

### Features
- may be watery or thicker (particulate)
- light yellow/green or dark green-black in colour

### Treatment
- call respiratory therapy, neonatology, or pediatrics to delivery room
- closely monitor FHR for signs of fetal distress

# Operative Obstetrics

## Operative Vaginal Delivery

### Definition
- forceps or vacuum extraction

### Indications
- fetal
  - atypical or abnormal fetal heart rate tracing, evidence of fetal compromise
  - consider if second stage is prolonged, as this may be due to poor contractions or failure of fetal head to rotate
- maternal
  - need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  - exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

### Contraindications
- unknown fetal head presentation
- unengaged head
- fetal bone demineralization disorder (e.g. osteogenesis imperfecta)
- fetal bleeding disorder (e.g. hemophilia or vWD)

**Prerequisites for Operative Vaginal Delivery**

**ABCDEFGHIJK**
**A**nesthesia (adequate)
**B**ladder empty
**C**ervix fully dilated and effaced with ROM
**D**etermine position of fetal head
**E**quipment ready (including facilities for emergent C/S)
**F**ontanelle (posterior fontanelle midway between thighs)
**G**entle traction
**H**andle elevated
**I**ncision (episiotomy)
Once **j**aw visible remove forceps
**K**nowledgeable operator

## Forceps

### Outlet Forceps Position
- head visible between labia in between contractions
- sagittal suture in or close to AP diameter
- rotation cannot exceed 45°

### Low Forceps Position
- presenting part at station +2 or greater
- subdivided based on whether rotation less than or greater than 45°

### Mid Forceps Position
- presenting part below spines but above station +2

### Types of Forceps
- Simpson or Tucker-McLane forceps for OA presentations
- Kielland (rotational) forceps when rotation of head or correction of asynclitism is required
- Piper forceps for after-coming head in breech delivery
- Wrigley's for preterm babies

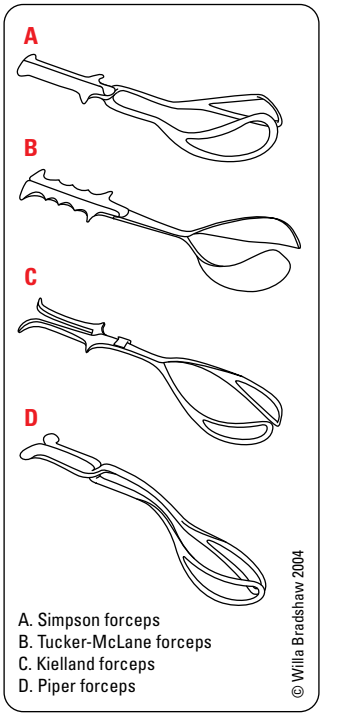


**Figure 8. Types of forceps**

## Vacuum Extraction

- traction instrument used as alternative to forceps delivery; aids maternal pushing
- contraindications: <34 wk GA (<2500 g), fetal head deflexed, fetus requires rotation, fetal condition (e.g. bleeding disorder)

**Limits for Trial of Vacuum**
- After 3 pulls over 3 contractions with no progress
- After 3 pop-offs with no obvious cause
- 20 min and delivery is not imminent

**Table 22. Advantages and Disadvantages of Forceps vs. Vacuum Extraction**

| | Forceps | Vacuum Extraction |
|---|---|---|
| **Advantages** | Higher overall success rate for vaginal delivery<br>Decreased incidence of fetal morbidity | Easier to apply<br>Less anesthesia required<br>Less maternal soft-tissue injury compared to forceps |
| **Disadvantages** | Greater incidence of maternal injury | Suitable only for vertex presentations<br>Maternal pushing required<br>Contraindicated in preterm delivery |
| **Complications** | Maternal: anesthesia risk, lacerations, injury to bladder, uterus, or bone, pelvic nerve damage, PPH, and infections<br>Fetal: fractures, facial nerve palsy, trauma to face/scalp, intracerebral hemorrhage, cephalohematoma, and cord compression | Increased incidence of cephalohematoma and retinal hemorrhages, and jaundice compared to forceps<br>Subgaleal hemorrhage<br>Subaponeurotic hemorrhage<br>Soft tissue trauma |

# Lacerations

- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter (partial IIIa or complete IIIb)
- fourth degree: extends through the anal sphincter into the rectal mucosa
- for third and fourth degree tears, a single prophylactic dose of IV antibiotics (2nd generation cephalosporin, e.g. cefoxitin or cefotetan) should be administered to reduce perineal wound complications; laxatives should also be prescribed and constipation should be avoided

# Episiotomy

## Definition

- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernosus muscles
  - heals better, but increases risk of 3rd/4th degree tears
- mediolateral: incision through bulbocavernosus, superficial transverse perineal muscle, and levator ani
  - reduced risk of extensive tear but more painful

## Indications

- to relieve obstruction of the unyielding perineum
- to expedite delivery (e.g. abnormal FHR pattern)
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

## Complications

- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, and incontinence

**Risk Factors for the Development of Obstetric Anal Sphincter Injuries in Modern Obstetric Practice**
Obstet Gynecol 2018;131(2):290-96
**Objective**: To characterize the rate of obstetric anal sphincter injuries and identify key risk factors of obstetric anal sphincter injuries, including duration of the second stage of labour.
**Methods**: Retrospective cohort study including all singleton, term, cephalic vaginal deliveries from 2013 to 2014.
**Results**: The overall incidence rate of obstetric anal sphincter injuries was 4.9% (3.6% of women who delivered spontaneously vs 24.0% of women who had a vacuum-assisted vaginal delivery, P<.001, CI 18.1–22.6%). In bivariate and multivariate analyses, obstetric anal sphincter injury incidence was higher among women with second stage of labour longer than 2 hours, Asian race, nulliparity, vaginal birth after cesarean delivery, episiotomy, and vacuum delivery. Women with a vacuum-assisted vaginal delivery had four times the odds of obstetric anal sphincter injury (adjusted odds ratio [OR] 4.23, 95% CI 3.59-4.98) and those whose second stage of labour lasted at least 180 minutes vs less than 60 minutes had three times the odds of incurring obstetric anal sphincter injury (adjusted OR 3.20, 95% CI 2.62-3.89).

# Cesarean Delivery

## Epidemiology

- overall 28% rate in Canada (range 18.5-35.3% by province/territory)

## Indications

- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery (past C/S is most common), and underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, and vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, and certain congenital anomalies

## Types of Cesarean Incisions

- skin
  - transverse (Pfannenstiel)
  - decreased exposure and slower entry
  - improved strength and cosmesis
  - vertical midline
  - rapid peritoneal entry and increased exposure
  - increased dehiscence
- uterine
  - low transverse (most common): in non-contractile lower segment
- decreased chance for rupture in subsequent pregnancies
  - low vertical
  - used for very preterm infants or poorly developed maternal lower uterine segment
  - classical (rare): in thick, contractile segment
  - used for transverse lie, preterm breech, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, and inaccessible lower uterine segment (e.g. morbid obesity)

## Risks/Complications

- anaesthetic complications (e.g. aspiration)
- hemorrhage (average blood loss ~1000 cc)
- infection (UTI, wound, and endometritis)
  - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- injury to surrounding structures (bowel, bladder, ureter, and uterus)
- thromboembolism (DVT, PE)
- increased recovery time/hospital stay
- maternal mortality (<0.1%)

**Common OR Questions**

**7 Layers to Dissect**
Skin, fatty layer, fascia, muscle separation (rectus abdominis), peritoneum, bladder flap, uterus

**Layers of the Rectus Sheath**
Above the arcuate line: external oblique, external internal oblique, internal oblique, rectus abdominis, internal internal oblique, transversus abdominis
Below the arcuate line: external oblique, internal oblique, transversus abdominis, rectus abdominis

**Name of the Obliterated Umbilical Ligament** Urachus

Most C/S performed with regional analgesia

# Trial of Labour after Cesarean Section (TOLAC)

- should be recommended if no contraindications after previous low transverse incision
- success rate varies with indication for previous C/S (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision), increased by interval <18 mo and one layer closure

Contraindications
- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- history of uterine surgery (e.g. myomectomy) or previous uterine rupture
- multiple gestation
- non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency C/S

**VBAC***
- Rate of successful VBAC ranges from 60-82%
- No significant difference in maternal deaths or hysterectomies between VBAC or C/S
- Uterine rupture more common in VBAC group
- Evidence regarding fetal outcome is lacking

*Safety of vaginal birth after Cesarean section: A systematic review. *Obstet Gynecol* 2004;103:420-9

# Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

# Postpartum Hemorrhage

## Definition
- loss of >1000 ml of blood or bleeding associated with signs/symptoms of hypovolemia within 24 hours of birthing process regardless of mode of delivery
- primary – within first 24 h postpartum
- secondary – after 24 h but within first 12 wk

## Epidemiology
- incidence 5-15%

## Etiology (4 Ts)
**1. Tone (uterine atony)**
- most common cause of PPH (70-80%)
- avoid with active management of 3rd stage of labour with 1) oxytocin administration 2) uterine massage 3) umbilical cord traction
- due to:
  - overdistended uterus (polyhydramnios, multiple gestations, and macrosomia)
  - uterine muscle exhaustion (prolonged or rapid labour, grand multiparity, oxytocin use, and general anesthetic)
  - uterine distortion (fibroids)
  - intra-amniotic infection (fever or prolonged ROM)
  - bladder distension (preventing uterine contraction)

**2. Tissue**
- retained placental products (membranes, cotyledon, or succenturiate lobe)
- retained blood clots in an atonic uterus
- gestational trophoblastic neoplasia
- abnormal placentation (e.g. placenta previa or placental abruption)

**3. Trauma**
- laceration (vagina, cervix, or uterus), episiotomy, hematoma (vaginal, vulvar, or retroperitoneal), uterine rupture, and uterine inversion

**4. Thrombin**
- coagulopathy (pre-existing or acquired)
  - most identified prior to delivery (low platelets increases risk)
  - includes hemophilia, DIC, ITP, TTP, and vWD (most common)
  - therapeutic anti-coagulation

Uterine atony is the most common cause of PPH

**DDx of Early PPH – 4 Ts**
**T**one (atony)
**T**issue (retained placenta, clots)
**T**rauma (laceration, inversion)
**T**hrombin (coagulopathy)

**DDx of Late PPH**
Retained products
± endometritis
Sub-involution of uterus

## Investigations
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of atony, retained tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

## Management
- ABCs, call for help
- 2 large bore IVs, run crystalloids wide open
- CBC, coagulation profile, cross and type pRBCs
- treat underlying cause
- Foley catheter to empty bladder and monitor urine output

### Medical Therapy
- oxytocin 10 IU IM is preferred in low-risk vaginal deliveries, oxytocin IV infusion (20-40 IU in 1000 mL crystalloid at 150 mL/h) is an acceptable alternative. Oxytocin 5-10 IU IV bolus (20-40 IU in 250 mL crystalloid) can be used after vaginal birth, but not with elective C/S
- carbetocin, a long-acting oxytocin, 100 μg IV bolus over 1 min for elective C/S or 100 ug IM for vaginal deliveries with 1 risk factor for PPH (instead of a continuous oxytocin infusion)
- methylergonavine maleate (ergotamine) 0.25 mg IM/IMM q15min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carboprost (Hemabate®), a synthetic PGF-1α analog, 250 μg IM/IMM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600-800 μg PO/SL (faster) or PR/PV (side effect: pyrexia if >600 μg)
- tranexamic acid (Cyklokapron®), an antifibrinolytic, 1 g IV

### Local Control
- bimanual massage: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

### Surgical Therapy (Intractable PPH)
- D&C (beware of vigorous scraping, which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), ovarian artery, or hypogastric artery, compression sutures (B-Lynch or Cho sutures)
- hysterectomy last option, with angiographic embolization if post-hysterectomy bleeding

## Retained Placenta

### Definition
- placenta undelivered after 30 min postpartum

### Etiology
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, and placenta percreta)

### Risk Factors
- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, and uterine infection

### Clinical Features
- risk of PPH and infection

### Investigations
- explore uterus
- assess degree of blood loss

### Management
- 2 large bore IVs, type and screen
- Brandt maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure cephalad to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required (U/S guidance if available)
- cefazolin 2 g IV if manual removal or D&C

## Uterine Inversion

### Definition
- inversion of the uterus through cervix ± vaginal introitus

### Etiology/Epidemiology
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous women (lax uterine ligaments)
- 1/1500-1/2000 deliveries

### Clinical Features
- can cause profound vasovagal response with bradycardia, vasodilation, and hypovolemic shock
- shock may be disproportionate to maternal blood loss

### Management
- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids
- can use tocolytic drug (see *Preterm Labour*, OB16) or nitroglycerin IV to relax uterus and aid replacement
- replace uterus without removing placenta
- remove placenta manually and withdraw slowly
- IV oxytocin infusion (only after uterus replaced)
- re-explore uterus
- may require general anesthetic ± laparotomy

## Postpartum Pyrexia

### Definition
- fever >38°C on any 2 of the first 10 d postpartum, except the 1st day

### Etiology
- endometritis
- wound infection (check C/S and episiotomy sites)
- mastitis/engorgement
- UTI
- atelectasis
- pneumonia
- DVT or pelvic thrombophlebitis

**Etiology of Postpartum Pyrexia**

**B-5W**
**B**reast: engorgement, mastitis
**W**ind: atelectasis, pneumonia
**W**ater: UTI
**W**ound: episiotomy, C/S site infection
**W**alking: DVT, thrombophlebitis
**W**omb: endometritis

### Investigations
- detailed history and physical exam, relevant cultures
- for endometritis: blood and genital cultures
- serum lactic acid for early detection of sepsis

### Treatment
- depends on etiology
  - infection: empiric antibiotics, adjust when sensitivities available
- endometritis: clindamycin + gentamicin IV
- mastitis: cloxacillin or cephalexin
- wound infection: cephalexin + frequent sitz baths for episiotomy site infection
  - DVT: anticoagulants
- prophylaxis against post-C/S endometritis: administer 2 g cefazolin IV 30 min prior to skin incision

**Risk Factors for Endometritis**
C/S, intrapartum chorioamnionitis, prolonged labour, prolonged ROM, multiple vaginal examinations

### ENDOMETRITIS
- definition: inflammation of the endometrium most commonly due to infection
- clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling vaginal discharge, or lochia
- treatment: depends on infection severity; oral antibiotics if well, IV antibiotics with hospitalization in moderate to severe cases

### VENOUS THROMBOEMBOLISM
- see *Venous Thromboembolism*, OB30

# Mastitis

- **definition**: inflammation of mammary glands
- must rule out inflammatory carcinoma, as indicated
- differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women

**Table 23. Lactational vs. Non-Lactational Mastitis**

| | Lactational | Non-Lactational |
|---|---|---|
| **Epidemiology** | More common than non-lactational<br>Often 2-3 wk postpartum | Periductal mastitis most common<br>Mean age 32 yr |
| **Etiology** | *S. aureus* | May be sterile<br>May be infected with *S. aureus* or other anaerobes<br>Smoking is risk factor<br>May be associated with mammary duct ectasia |
| **Symptoms** | Unilateral localized pain<br>Tenderness<br>Erythema | Subareolar pain<br>May have subareolar mass<br>Discharge (variable colour)<br>Nipple inversion |
| **Treatment** | Heat or ice packs<br>Continued nursing/pumping<br>Antibiotics (cloxacillin/cephalexin) (erythromycin if penicillin-allergic) | Broad-spectrum antibiotics and I&D<br>Total duct excision (definitive) |
| **Abscess** | Fluctuant mass<br>Purulent nipple discharge<br>Fever, leukocytosis<br>Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&D usually required | If mass does not resolve, fine-needle aspiration to exclude cancer and U/S to assess presence of abscess<br>Treatment includes antibiotics, aspiration, or I&D (tends to recur)<br>May develop mammary duct fistula<br>A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually *S. aureus*) |

# Postpartum Mood Alterations

## POSTPARTUM BLUES

- 40-80% of new mothers, onset day 3-10; extension of the "normal" hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency, anxiety, and insomnia

## POSTPARTUM DEPRESSION

- **definition**: major depression occurring in a woman within 6 mo of childbirth (see Psychiatry, PS12)
- **epidemiology**: 10-15%, risk of recurrence 50%
- **risk factors**
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- **clinical features**: suspect if the "blues" last beyond 2 wk, or if the symptoms in the first 2 wk are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
- **assessment**: Edinburgh Postnatal Depression Scale or others
- **treatment**: antidepressants, psychotherapy, supportive care, and ECT if refractory
- **prognosis**: interferes with bonding and attachment between mother and baby, so it can have long-term effects

## POSTPARTUM PSYCHOSIS

- **definition**: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- **epidemiology**: rare (0.2%)

# Postpartum Care

## Postpartum Office Visit at 6 Weeks

### Care of Mother (The 10 Bs)

- **B**e careful: do not use douches or tampons for 4-6 wk post-delivery
- **B**e fit: encourage gradual increases in walking, Kegel exercises
- **B**irth control: assess for use of contraceptives
- **B**reastfeeding is NOT an effective method of birth control (see Gynecology, GY15, for more detail about different contraceptive options postpartum)
- **B**ladder: assess for urinary incontinence, maintain high fluid intake
- **B**lood pressure: especially if gestational HTN
- **B**lood tests: CBC (for anemia if had PPH)
- **B**lues: (see *Postpartum Mood Alterations*, OB47)
- **B**owel: fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, sitz baths, and ice compresses
- **B**reast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk if due for screening

The acronym "**BUBBLES**" for what to ask about when rounding on postpartum care. Modify this for C/S or vaginal delivery

**B**aby care and breastfeeding-- Latch? Amount?
**U**terus – firm or boggy?
**B**ladder function – Voiding well? Dysuria?
**B**owel function – Passing gas or stool? Constipated?
**L**ochia or discharge – Any blood?
**E**pisiotomy/laceration/incision – Pain controlled?
**S**ymptoms of VTE – Dyspnea? Calf pain?

### Physiological Changes Postpartum

- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d after giving birth, non-lactating women usually ovulate sooner than lactating women
- lochia: normal vaginal discharge postpartum, uterine decidual tissue sloughing
  - decreases and changes in colour from red (lochia rubra; presence of erythrocytes, 3-4 d) → pale (lochia serosa) → white/yellow (lochia alba; residual leukorrhea) over 3-6 wk
- foul-smelling lochia suggests endometritis

### Breastfeeding Problems

- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisturizer, topical steroid if needed
- mastitis: treat promptly (see *Postpartum Pyrexia*, OB46)
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see *Breastfeeding and Drugs*, OB48)

### Bladder Dysfunction

- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management for stress and urge incontinence: pelvic floor retraining with Kegel exercises/pelvic physiotherapy, vaginal cones or pessaries, and lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management for stress incontinence: midurethral slings including retropubic tension free vaginal tape (TVT) or transobturator tape (TOT), retropubic urethropexy (Burch), urethral bulking

### Puerperal Pain

- "after pains" common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

# Breastfeeding and Drugs

**Table 24. Drug Safety During Breastfeeding**

| Safe During Breastfeeding | Contraindicated When Breastfeeding |
|---|---|
| Analgesics (e.g. acetaminophen, NSAIDs) | Chloramphenicol (bone marrow suppression) |
| Anticoagulants (e.g. heparin) | Cyclophosphamide (immune system suppression) |
| Antidepressants (e.g. sertraline, fluoxetine, tricyclic antidepressants) | Sulphonamides (in G6PD deficiency, can lead to hemolysis) |
| Antiepileptics (e.g. phenytoin, carbamazepine, valproic acid) | Nitrofurantoin (in G6PD deficiency, can lead to hemolysis) |
| Antihistamines | Tetracycline |
| Antimicrobials (e.g. penicillins, aminoglycosides, cephalosporins) | Lithium |
| β-adrenergics (e.g. propanolol, labetalol) | Phenindione |
| Insulin | Bromocriptine |
| Steroids | Anti-neoplastics and immunosuppresants |
| OCP (low dose) – although may decrease breast milk production | Psychotropic drugs (relative contraindication) |

# Common Medications

**Table 25. Common Medications**

| Drug Name (Brand Name) | Dosing Schedule | Indications/Comments |
|---|---|---|
| **betamethasone valerate (Celestone®)** | 12 mg IM q24h x 2 doses | Enhancement of fetal pulmonary maturity for PTL |
| **carboprost (Hemabate®)** | 0.25 mg IM/IMM q15min<br>Max 2 mg | Treatment of uterine atony |
| **cefazolin** | 2 g IV then 1 g q8h | GBS prophylaxis (penicillin allergic and not at risk for anaphylaxis) |
| **clindamycin** | 900 mg IV q8h | Used in endometritis |
| **dexamethasone** | 6 mg IM q12h x 4 doses | Enhancement of fetal pulmonary maturity for PTL |
| **dinoprostone (Cervidil®: PGE2 impregnated thread)** | 10 mg PV (remove after 12 h)<br>Max 3 doses | Induction of labour<br>Advantage: can remove if uterine hyperstimulation |
| **doxylamine succinate (Diclectin®)** | 2 tabs qhs + 1 tab qam + 1 tab qpm<br>Max 8 tabs/d | Each tablet contains 10 mg doxylamine succinate with vitamin B6<br>Used first-line for N/V in pregnancy, including hyperemesis gravidarum |
| **erythromycin** | 500 mg IV q6h | GBS prophylaxis (penicillin allergic and at risk for anaphylaxis) |
| **folic acid** | 0.4-1 mg PO OD x 1-3 mo preconception and T1<br>5 mg PO OD with past Hx of NTD/risks for NTD | Prevention of ONTD |
| **methotrexate** | 50 mg/mL IM or 50 mg PO x 1 dose | For ectopic pregnancy or medical abortion |
| **methylergonavine maleate (Ergotamine®)** | 0.25 mg IM/IMM q15min up to 1.25 mg<br>or IV bolus 0.125 mg | Treatment of uterine atony |
| **misoprostol (Cytotec®)** | 600-1000 µg PR x 1 dose<br>400 µg PO/SL x 1 dose<br>or 800 µg PV x 1 dose 3-7 d after methotrexate | For treatment of PPH<br>For medical abortion/retained products of conception |
| **oxytocin (Pitocin®)** | 0.5-2.0 mU/min IV or 10 U/L NS increase by 1-2 mU/min q20-60min<br>Max 36-48 mU/min<br>10 IU IM at delivery of anterior shoulder and of placenta<br>20 IU/L NS or RL IV continuous infusion | Augmentation of labour (also induction of labour)<br>Prevention of uterine atony<br>Treatment of uterine atony |
| **Penicillin G** | 5 million IU IV, then 2.5 million IU IV q4h until delivery | GBS prophylaxis |
| **PGE2 gel (Prostin® gel)** | 0.5 mg PV q6-12h; max 3 doses | Induction of labour |
| **Rh IgG (Rhogam®)** | 300 µg IM x 1 dose | Given to Rh-negative women<br>Routinely at 28 wk GA<br>Within 72 h of birth of Rh+ fetus<br>Positive Kleihauer-Betke test<br>With any invasive procedure in pregnancy<br>Ectopic pregnancy<br>Antepartum hemorrhage<br>Miscarriage or therapeutic abortion (dose: 50 µg IM only) |

Not every red eye has conjunctivitis

# Vision Pain

### Differential Diagnosis - Acute

- vitreous hemorrhage
- retinal artery/vein occlusion
- RD
- AION
- optic neuritis
- amaurosis fugax/TIA/stroke

### Differential Diagnosis - Chronic

- cataract
- refractive error
- corneal dystrophy
- glaucoma
- AMD
- DR

# Ocular Pain

- differentiate from eye fatigue (asthenopia)
- ocular surface disease
- herpes zoster prodrome
- trauma/foreign body
- blepharitis
- keratitis
- corneal abrasion/ulcer
- acute glaucoma
- acute uveitis
- scleritis
- episcleritis
- optic neuritis

# Floaters

- PVD (often secondary to age-related vitreous syneresis)
- vitreous hemorrhage
- retinal tear/detachment
- intermediate uveitis (pars planitis)
- posterior uveitis (chorioretinitis)

# Flashes of Light (Photopsia)

- PVD (often secondary to age-related vitreous syneresis)
- retinal tear/detachment
- migraine with aura

# Photophobia (Severe Light Sensitivity)

- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis/encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

# Diplopia (Double Vision)

**Table 3. Common Causes of Diplopia**

| Binocular Diplopia | Monocular Diplopia |
|---|---|
| **Definition** | |
| Occurs with both eyes open, eliminated with occlusion of either eye | Occurs with one eye open, remains with occlusion of unaffected eye |
| **Causes** | |
| Congenital: strabismus syndromes | Optical factors: refractive error/astigmatism |
| Ocular motor nerve dysfunction: III, IV, VI Nerve Palsy | Mechanical process: dislocated lens, postoperative sequelae (cataract surgery, peripheral laser iridotomy) |
| Neuromuscular junction disease: myasthenia gravis, botulism | Other: strands of mucus in tear film (keratoconus) |
| Mechanical process: muscle restriction/entrapment, thyroid ophthalmopathy | |
| **Supranuclear Causes: INO (multiple sclerosis, brainstem infarct)** | |

# Ocular Problems in the Contact Lens Wearer

- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- SPK from dry eyes
- limbal stem cell deficiency
- corneal neovascularization
- sterile corneal infiltrates (immunologic)
- infected ulcers (*Pseudomonas*, *Acanthamoeba*)

# Ocular Emergencies

**These require urgent ophthalmology consultation for management**

### Sight-Threatening

- lid laceration
- globe rupture
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis
- GCA

### Life-Threatening

- proptosis (rule out cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or externally compressive neoplastic lesion)
- papilledema (elevated or increased ICP workup)
- orbital cellulitis
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma, especially in children)

# The Ocular Examination

### Visual Acuity – Distance

- Snellen Acuity = $\frac{\text{testing distance (usually 20 ft or 6 m)}}{\text{smallest line patient can read on the chart}}$
  - e.g. 20/40 = what the patient can see at 20 feet away (numerator) is what a "normal" person can see at 40 feet away (denominator)
- distance visual acuity should be tested with distance glasses on in order to obtain best-corrected visual acuity
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)
- legal blindness is BCVA that is ≤20/200 in best eye

**Example 1**

$\overline{SC}$ V 20/40 −1
20/80 +2 → 20/25 PH

**Example 2**

$\overline{CC}$ V CF 3'
HM

**Note:** RIGHT EYE visual acuity always listed on top.

| | |
|---|---|
| **V** | Vision |
| **SC** | Without correction |
| **CC** | With correction |
| **20/40 -1** | All except one letter of 20/40 |
| **20/80+2** | All of 20/80 plus two letters of 20/70 |
| **PH** | Visual acuity with pinhole correction |
| **CF** | Counting fingers |
| **HM** | Hand motion |

**Figure 5. Ophthalmology nomenclature for visual acuity**

OD = oculus dexter = right eye
OS = oculus sinister = left eye
OU = oculus uterque = both eyes

Snellen visual acuity of 20/20 equates to "normal" vision

**Normal Infant and Child Visual Acuity**

- 6-12 mo: 20/120
- 1-2 yr: 20/80
- 2-4 yr: 20/20

- minimum visual requirements to operate a non-commercial automobile in Ontario are: 20/50 BCVA with both eyes open and examined together, 120° continuous horizontal visual field, and 15° continuous visual field above and below fixation

### Visual Acuity – Near
- use pocket vision chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance visual acuity possible (e.g. immobile patient, no distance chart available)

### Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics
- newborns
  - VA cannot be tested conventionally
- 3 mo-3 yr: can only assess visual function, not acuity
  - test each eye for fixation symmetry using an interesting object
  - normal function noted as "CSM" = central, steady, and maintained
- 3 yr until alphabet known
  - pictures or letter cards/charts such as HOTV or Sheridan-Gardiner test (children point to optotypes on a matching card)
  - tumbling "E" chart

### Colour Vision
- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye, specify incorrect plates
- important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
- note: red-green colour blindness is sex-linked and occurs in 7-10% of males

## VISUAL FIELDS
- test "visual fields by confrontation" (4 quadrants, each eye tested separately) for estimation of visual field loss
- accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- use Amsler grid (each eye tested separately) to check for central or paracentral scotomas (blind spots) in patients with AMD

## PUPILS
- use reduced room illumination with patient focusing on distant, fixed object to prevent near reflex
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- test for RAPD with swinging flashlight test, check by reverse RAPD test if one pupil non-reactive
- test pupillary constriction portion of near reflex by bringing object close to patient's nose
- "normal" pupil testing often noted as PERRLA (pupils equal, round, reactive to light and accommodation)

## ANTERIOR CHAMBER DEPTH
- shine light tangentially from temporal side
- if >2/3 of nasal side of iris in shadow → shallow anterior chamber

### The Van Herick Method (Slit Lamp technique)
- shine thin-angled slit beam onto the peripheral cornea of each eye, view at a 60° angle from the beam
- estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
- ratios ≤1/4 implies risk of occludable angle; however, if >1/4, this does not rule out risk
- gonioscopy, as performed by an ophthalmologist, is gold-standard for assessing anterior chamber depth

## EXTRAOCULAR MUSCLES

### Alignment
- Hirschberg corneal reflex test
  - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  - shine light into patient's eyes from ~30 cm away
  - corneal light reflex should be at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see *Strabismus*, OP36)

### Movement
- examine movement of eyeball through six cardinal positions of gaze
- ask patient if diplopia or pain is present in any position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal

### Diplopia
- see Neurology, N16

Test pupils using an ophthalmoscope focused on the red reflex; this will provide a better view than using a penlight

**4 Ps of Inspection**
**P**upil: shape, size, symmetry
**P**osition: esotropia, exotropia, central
**P**tosis
**P**rimary nystagmus

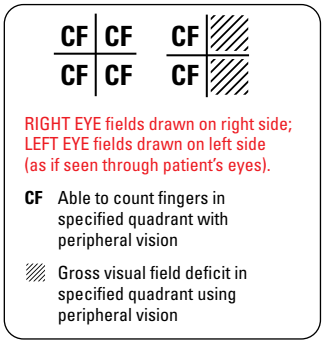

**Figure 6. Ophthalmology nomenclature for visual fields by confrontation**

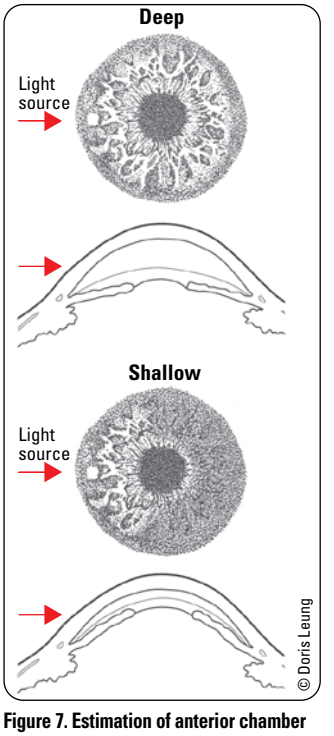

**Figure 7. Estimation of anterior chamber depth**

## SLIT-LAMP EXAMINATION

### Ocular Adnexa
- lids, lashes, lacrimal system

### Anterior Segment
- conjunctiva / sclera
- cornea
  - fluorescein dye: stains de-epithelialized cornea; dye appears fluorescent green with cobalt blue filtered light
  - Rose Bengal dye: stains devitalized corneal epithelium
- anterior chamber/angle (Van Herick)
- iris/pupil
- lens (assess for cataract)
- anterior vitreous

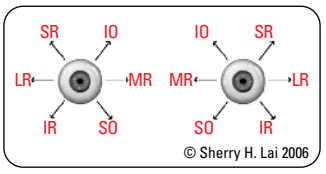
### Posterior Segment (requires 78D or 90D lens)
- vitreous
- optic disc (colour, C:D ratio, sharpness of disc margin)
- macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
- retinal vessels
- retinal background

## TONOMETRY
- measurement of IOP
- normal range is 9-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by:
  - GAT: clinical gold standard, performed using the slit-lamp with special tip (prism)
  - Tono-Pen®: benefit is portability and use of disposable probe tips; use when GAT is inaccurate, such as when the cornea is scarred or asymmetric
  - non-contact tonometer (NCT): air puff, least reliable
- use topical anesthetic for GAT and Tono-Pen®; apply fluorescein dye and use cobalt blue light for GAT

## DIRECT OPHTHALMOSCOPY
- best performed with pupils dilated (for list of mydriatics and cycloplegics see Table 13, OP42)
  1. assess red reflex
     - light reflected off the retina produces a "red reflex" when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract, retinoblastoma)
  2. examine the posterior segment of the eye
     - vitreous
     - optic disc (colour, C:D ratio, sharpness of disc margin)
     - macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
- contraindications to pupillary dilatation
  - shallow anterior chamber – can precipitate acute angle-closure glaucoma
  - iris-supported anterior chamber lens implant
  - potential neurologic abnormality requiring pupil evaluation
  - use caution with cardiovascular disease – mydriatics may cause tachycardia and HTN

# Optics

## REFRACTION
- two techniques used
  - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
  - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
  - cycloplegic: manifest refraction with accommodation temporarily paralyzed with cycloplegics
- a typical lens prescription would contain:
  - sphere power in diopter (measurement of refractive power of lens, equal to reciprocal of focal length in metres)
  - cylinder power in diopter to correct astigmatism
  - axis of cylinder in degrees
  - "add" (bifocal/progressive reading lens) for presbyopes
  - e.g. -1.50 + 1.00 x 120°, add +2.00



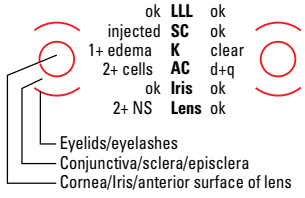


**Figure 8. Diagnostic positions of gaze for isolated primary actions of extraocular muscles**

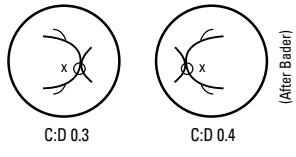
**L**ateral **R**ectus via CN **VI**
**S**uperior **O**blique via CN **IV**
**A**ll **E**lse via CN **III** (superior, medial, and inferior rectus, inferior oblique)



**Aqueous Flare**
- Resembles dust particles in a beam of light
- Results from protein leaking from blood vessels
- Distinguish from aqueous cells (individual cells in anterior chamber)

**Note:** RIGHT EYE drawn on the left, LEFT EYE drawn on the right (as if looking at patient's face)

| | |
|---|---|
| **LLL** | Lids, lashes, lacrimal |
| **SC** | Sclera, conjunctiva |
| **K** | Cornea |
| **AC** | Anterior chamber |
| **d+q** | Deep (not shallow) and quiet (no cells in AC) |
| **NS** | Nuclear sclerosis (cataract) |

| x | Fovea |

Any abnormality or pathology is drawn on the sketch in the appropriate location, and is labelled (e.g. trichiasis, conjunctivitis/episcleritis/scleritis, corneal abrasion/ulcer, foreign body, etc.)

© Tobi Lam 2012

**Figure 9. Slit-lamp examination note**

**Note:** RIGHT EYE IOP always listed on top. Always include time.

Note method used to measure IOP (GAT, Tono-Pen®, airpuff).

**Figure 10. Tonometry**

## REFRACTIVE EYE SURGERY

- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK
- potential risks/side-effects: infection, under/overcorrection, increased glare/halo perception at night, corneal haze (PRK only), dry eyes (more common in LASIK than PRK), regression, and flap complications such as free cap (loss of flap), traumatic flap dislocations, buttonhole flap, and epithelial ingrowth (LASIK only)

**Central Corneal Thickness (CCT)**
Average CCT = 550 µm
By GAT, IOP is over-estimated with thick corneas and under-estimated with thin corneas

### Table 4. Optics

| | Pathophysiology | Clinical Features | Treatment | Complications |
|---|---|---|---|---|
| **Emmetropia** | Image of distant objects focus exactly on the retina | No refractive error | | |
| **Myopia** | Globe too long relative to refractive mechanisms, or refractive mechanisms too strong<br>Light rays from distant object focus in front of retina → blurring of (distance) vision | "Nearsightedness"<br>Usually presents in 1st or 2nd decade, stabilizes in 2nd and 3rd decade; rarely begins after age 25 except in patients with DM or cataracts<br>Blurring of distance vision; near vision usually unaffected<br>Prevalence: 30-40% in U.S. population; higher among Asians | Correct with negative diopter/concave/"negative" lenses to diverge light rays<br>Refractive eye surgery | Retinal tear/detachment, myopic maculoschisis leading to formation of macular hole, open-angle glaucoma<br>Other complications that are not prevented with refractive correction |
| **Hyperopia** | Globe too short relative to refractive mechanisms, or refractive mechanisms too weak<br>Light rays from distant object focus behind retina → blurring of near ± distant vision<br>May be developmental or due to any etiology that shortens globe | "Farsightedness"<br>Youth: usually do not require glasses (still have sufficient accommodative ability to focus image on retina), but may develop accommodative esotropia (see *Strabismus*, OP36)<br>30s-40s: blurring of near vision due to decreased accommodation, may need reading glasses<br>>50s: blurring of distance vision due to severely decreased accommodation | When symptomatic, correct with positive diopter/convex/"plus" lenses to converge light rays<br>Refractive eye surgery | Angle-closure glaucoma, particularly later in life as lens enlarges |
| **Astigmatism** | Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped)<br>**Two types**<br>Regular – curvature uniformly different in meridians at right angles to each other<br>Irregular – distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye | Affects ~30% of population, with prevalence increasing with age<br>Mild astigmatism unnoticeable<br>Higher amounts of astigmatism may cause blurry vision, squinting, asthenopia, or headaches | Correct with cylindrical lens (if regular)<br>Try contact lens (if irregular)<br>Refractive eye surgery | |
| **Presbyopia** | Normal aging process (>40 yr)<br>Hardening/reduced deformability of lens results in decreased accommodative ability<br>Accommodative power is 14D at age 10, diminishes to 3.5D by age 40 yr<br>Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia) | If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected<br>If initially myopic, person removes distance glasses to read<br>If initially hyperopic, symptoms of presbyopia occur earlier | Correct with positive diopter/convex/"plus" lenses for reading | |
| **Anisometropia** | Difference in refractive errors between eyes | | | Second most common cause of amblyopia in children |

**Myopia**

**LMN**
**L**ong globe
**M**yopic
**N**egative correction/**N**earsighted

# The Orbit

## Globe Displacement

**Table 5. Exophthalmos (Proptosis) and Enophthalmos**

| | Exophthalmos (Proptosis) | Enophthalmos |
|---|---|---|
| **Definition** | Anterior displacement (protrusion) of the globe<br>Exophthalmos generally refers to an endocrine etiology or protrusion of >18 mm (as measured by a Hertel exophthalmometer)<br>Proptosis generally refers to other etiologies (e.g. cellulitis) or protrusion of <18 mm | Posterior displacement (retraction) of the globe |
| **Investigations** | CT/MRI head/orbits, ultrasound orbits, thyroid function tests | CT/MRI orbits |
| **Etiology** | Note: rule out pseudoexophthalmos (e.g. lid retraction)<br>Graves' disease (unilateral or bilateral, most common cause in adults)<br>Orbital cellulitis (unilateral, most common cause in children)<br>1° or 2° orbital tumour<br>Orbital/retrobulbar hemorrhage<br>Cavernous sinus thrombosis or fistula | "Blow-out" fracture (see *Ocular Trauma*, OP40)<br>Orbital fat atrophy<br>Congenital abnormality<br>Metastatic disease |

## Preseptal Cellulitis

### Definition
- infection of soft tissue anterior to orbital septum

### Etiology
- usually follows periorbital trauma or dermal infection

### Clinical Features

**Table 6. Clinical Features of Preseptal and Orbital Cellulitis**

| Finding | Preseptal Cellulitis | Orbital Cellulitis |
|---|---|---|
| **Fever** | May be present | Present |
| **Lid Edema** | Moderate to severe | Severe |
| **Conjunctival Injection** | Absent | Present |
| **Chemosis** | Absent or mild | Marked |
| **Proptosis** | Absent | Present |
| **Pain on Eye Movement** | Absent | Present |
| **Ocular Mobility** | Normal | Decreased |
| **Vision** | Normal | Diminished ± diplopia |
| **RAPD** | Absent | May be seen if severe |
| **Leukocytosis** | Moderate | Marked |
| **ESR** | Normal or elevated | Elevated |
| **Additional Findings** | Skin infection | Sinusitis, dental abscess |

### Treatment
- systemic antibiotics (suspect *H. influenzae* in children; *S. aureus* or *Streptococcus* in adults)
  - e.g. amoxicillin-clavulanic acid
- if severe or child <1 yr, treat as orbital cellulitis

**Role of Oral Corticosteroids in Orbital Cellulitis**
Am J Ophthalmol 2013;156:178-183
**Purpose**: To evaluate the role of oral corticosteroids as an anti-inflammatory adjunct for the treatment of orbital cellulitis.
**Study**: RCT. Patients with acute onset (within 14 d) of orbital cellulitis with or without abscess. 21 patients total (7 patients in group 1: standard intravenous antibiotics; 14 patients in group 2: adjuvant steroids).
**Results**: Patients in group 2 showed earlier resolution of periorbital edema, conjunctival chemosis, pain, proptosis, and EOM deficits, including decreased duration of intravenous antibiotics and hospital stay ($p<0.05$ for all).
**Conclusion**: The use of oral steroids as an adjunct to intravenous antibiotics for orbital cellulitis may decrease inflammatory symptoms with a low risk of worsening infection.

## Orbital Cellulitis

### Definition
- **OCULAR** and **MEDICAL EMERGENCY**
- inflammation of orbital contents posterior to orbital septum
- common in children, elderly, and immunocompromised

### Etiology
- usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

### Clinical Features (see Table 6)

### Treatment
- admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
- surgical drainage of abscess with close follow-up, especially in children

### Complications
- optic nerve inflammation, cavernous sinus thrombosis, meningitis, brain abscess with possible loss of vision, and death

# Lacrimal Apparatus

- tear film made up of three layers
  - outer oily layer (reduces evaporation): secreted by the meibomian glands
  - middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  - inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
- tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrimal duct → nasal cavity behind inferior concha (Figure 3)

## Dry Eye Syndrome (Keratoconjunctivitis Sicca)

### Definition and Etiology
- aqueous-deficient
  - Sjögren syndrome (autoimmune etiology e.g. RA, SLE)
  - non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β-blockers)
- evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  - meibomian gland dysfunction (posterior blepharitis)
  - vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  - eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  - topical ocular medications with preservatives
  - contact lenses, allergic conjunctivitis
- mixed etiologies are common

### Clinical Features
- dry eyes, red eyes, foreign body sensation, blurred vision, tearing
- slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be 10 s), punctate staining of cornea with fluorescein

### Investigations
- surface damage observed with fluorescein/Rose Bengal staining
- decreased distance in Schirmer's test

### Complications
- erosions and scarring of cornea

### Treatment
- medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used more than 4-6x/d), short course of mild topical corticosteroid, omega-3 fatty acids orally (controversial), and eyelid hygiene for blepharitis
  - for moderate cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) or lifitegrast 5% (Xiidra®) can be used
- procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
- treat underlying cause

Long-term use of artificial tears with preservatives should be avoided when treating dry eyes

## Epiphora (Excessive Tearing)

### Etiology
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, dacryoadenitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

Excessive tearing can be caused by dry eyes – if the tear quality is insufficient, "reflex tearing" may occur

### Investigations
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

### Treatment
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation (dilation and irrigation)
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy – forming a new connection between the lacrimal sac and the nasal cavity

## Dacryocystitis

### Etiology
- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with *S. aureus, S. pneumoniae, Pseudomonas* species

### Clinical Features
- pain, swelling, redness over lacrimal sac at medial canthus
- epiphora, crusting, ± fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

### Treatment
- warm compresses, nasal decongestants, systemic and topical antibiotics (cephalexin if afebrile; cefazolin if febrile)
- incision and drainage; if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy

## Dacryoadenitis

### Etiology
- most commonly seen in children and young adults
- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: *S. aureus*, mumps, EBV, herpes zoster, *N. gonorrhoeae*
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

### Clinical Features
- pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

### Treatment
- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

# Lids and Lashes

## Lid Swelling

### Etiology
- commonly due to allergy, with shriveling of skin between episodes
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, thyroid disease (e.g. myxedema), trauma, and chemosis

## Ptosis

### Definition
- drooping of upper eyelid

### Etiology
- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
  - incomplete opening of eyelid due to mass or scarring
- neuromuscular
  - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  - CN III palsy
  - Horner's syndrome (see *Constricted Pupil, Horner's Syndrome*, OP30)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)
- drugs (e.g. high dose opioids, heroin abuse, pregabalin)

### Treatment
- surgery (e.g. blepharoplasty, levator resection, Müller's muscle resection, frontalis sling)

# Trichiasis

### Definition
- eyelashes turned inwards

### Etiology
- may result from entropion, involutional age change, chronic inflammatory lid diseases (e.g. blepharitis), trauma, burns

### Clinical Features
- patient complains of red eye, foreign body sensation, significant discomfort, tearing
- may result in corneal ulceration and scarring

### Treatment
- topical lubrication, repeat eyelash epilation, electrolysis, and cryotherapy

# Entropion

### Definition
- lid margin folds inward towards globe

### Etiology
- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

**Testing for Entropion**
Forced lid closure: Ask patient to tighten lid then open. In entropion, lid rolls inwards

### Clinical Features
- tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause corneal abrasions with secondary corneal scarring

### Treatment
- lubricants, evert lid with tape, and surgery

# Ectropion

### Definition
- lid margin folds outward from globe

### Etiology
- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumour, herniated fat)
- congenital

**Testing for Ectropion**
Snapback test: Pull eyelid inferiorly. In ectropion, lid remains away from globe

### Clinical Features
- tearing and possibly exposure keratitis

### Treatment
- topical lubrication, eyelid taping overnight, and surgery

# Hordeolum (Stye)

### Definition
- acute inflammation of eyelid gland: either meibomian glands (internal lid), glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)

### Clinical Features
- infectious agent is usually *S. aureus*
- painful, red swelling of lid

**Hordeolum vs. Chalazion**
Hordeolums are due to an infectious etiology, whereas chalazions are granulomatous inflammation

### Treatment
- warm compresses, lid care, gentle massage
- topical antibiotics are typically ineffective
- usually resolves within 2 wk, but may require incision and drainage

# Chalazion

### Definition
- chronic granulomatous inflammation of meibomian gland often preceded by an internal hordeolum

### Clinical Features
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, meibomian gland carcinoma

### Treatment
- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

## Blepharitis

### Definition
- inflammation of lid margins

### Etiology
- anterior blepharitis
  - staphylococcus (*S. aureus*): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales
- posterior blepharitis
  - meibomian gland dysfunction

### Clinical Features
- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids ("toothpaste sign")

### Complications
- recurrent hordeola
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

### Treatment
- warm compresses, lid massages, and lid washing using commercially available eyelid scrub solution
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids, omega-3 fatty acids

## Xanthelasma

### Definition
- eyelid xanthoma (lipid deposits in dermis of lids)

### Clinical Features and Associations
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (~50% of patients)
- common in the elderly, more concerning in the young

### Treatment
- excision for cosmesis only, commonly recurs

# Conjunctiva

- thin, vascular mucous membrane
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

## Pinguecula

### Definition
- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea

### Clinical Features
- associated with sun and wind exposure, aging
- benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops

## Pterygium

### Definition
- fibrovascular, triangular, wing-like encroachment of epithelial tissue onto the cornea

### Clinical Features
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (~5%)

# Subconjunctival Hemorrhage

- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN, anticoagulation
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- 360° involvement should be highly suspicious for globe rupture if trauma history
- if recurrent, consider medical/hematologic workup

# Conjunctivitis

## Etiology
- infectious
  - bacterial, viral, chlamydial, gonococcal, fungal, and parasitic
- non-infectious
  - allergic, atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - secondary to another disorder: dacryocystitis, dacryoadenitis, cellulitis, and systemic inflammatory disease

**Types of Discharge**
- Allergic: mucoid
- Viral: watery
- Bacterial: purulent
- Chlamydial: mucopurulent

## Clinical Features
- red eye (conjunctival injection often with limbal pallor), chemosis, and corneal subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, and lid edema
- ± preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva, overlain by vessels
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

- Follicles are usually seen in viral and chlamydial conjunctivitis
- Papillae are usually seen in allergic and bacterial conjunctivitis

## Allergic Conjunctivitis
- associated with rhinitis, asthma, dermatitis, and hay fever
- ocular pruritus, small papillae, chemosis, redness, thickened and erythematous lids
- seasonal (pollen, grasses, plant allergens)

## Treatment
- allergen avoidance, cool compresses, non-preserved artificial tears, topical or oral antihistamine, topical mast cell stabilizer (e.g. cromolyn, ketotifen, olopatadine), and topical corticosteroids

**Antibiotics vs. Placebo for Acute Bacterial Conjunctivitis**
Cochrane DB Syst Rev 2012;9:CD001211
**Purpose**: To assess the benefits and harms of antibiotic therapy in the management of acute bacterial conjunctivitis.
**Criteria**: RCTs with any form of antibiotic treatment compared with placebo including topical, systemic or combined (e.g. antibiotics and steroids) antibiotic treatments.
**Results**: 11 RCTs, 3673 participants. Topical antibiotics improve early (2-5 d) clinical and microbiological remission rates (RR 1.36, 95% CI 1.15-1.61; RR 1.55; 95% CI 1.37-1.76) and benefit clinical remission and microbiological cure rates at a late time point (6-10 d) (RR 1.21, 95% CI 1.10-1.33; RR 1.37, 95% CI 1.24-1.52). By 6-10 d 41% of cases had resolved in the placebo group. No serious outcomes were reported in any group.
**Conclusion**: The use of antibiotic eye drops is associated with modestly improved rates of clinical and microbiological remission in comparison to placebo. Antibiotic eye drops should therefore be considered in order to speed the resolution of symptoms and infection although acute bacterial conjunctivitis is frequently self-limiting.

## Atopic Conjunctivitis
- onset late adolescence and early adulthood with peak between 30-50 yr old
- intense ocular pruritus (perennially), tearing, burning, clear mucus discharge, redness, blurry vision, photophobia, and foreign body sensation
- thickened and intermittent swelling of the eyelids, conjunctival chemosis, conjunctival hyperemia, and tarsal papillary hypertrophy (Figure 13)
- severe cases lead to sub-epithelial fibrosis, fornix foreshortening, and corneal neovascularization

## Treatment
- calcineurin inhibitor ointment (e.g. tacrolimus and pimecrolimus), and topical corticosteroid (clobetasone)

## Giant Papillary Conjunctivitis
- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva

## Treatment
- clean, change or discontinue use of contact lens, and topical corticosteroids

## Vernal Conjunctivitis
- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves

## Treatment
- non-preserved artificial tears, consider topical steroid, topical cyclosporine (by ophthalmologist)

## Viral Conjunctivitis (pink eye)
- presents with itchiness, pain and swelling
- serous discharge, lid edema, follicles, and pseudomembranes
- subepithelial corneal infiltrates
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye within a few days
- mainly due to adenovirus – highly contagious for up to 12 d

## Treatment
- cool compresses, topical lubrication
- usually self-limiting (7-12 d)
- proper hygiene is important to prevent transmission

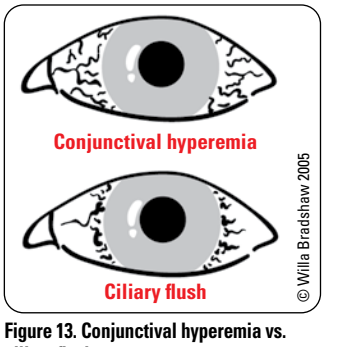

**Figure 13. Conjunctival hyperemia vs. ciliary flush**

### Bacterial Conjunctivitis
- purulent discharge, lid swelling, papillae, conjunctival injection, and chemosis
- common agents include *S. aureus, S. pneumoniae, H. influenzae* and *M. catarrhalis*
- in neonates or if sexually active must consider *N. gonorrhoeae* (invades cornea to cause keratitis)
- *C. trachomatis* is the most common cause in neonates

### Treatment
- topical broad-spectrum antibiotic, systemic antibiotics if indicated (especially in neonates and children)
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

### Gonococcal and Chlamydial Conjunctivitis
- caused by *N. gonorrhoeae* and *C. trachomatis*, respectively
- affects sexually active individuals, neonates (ophthalmia neonatorum) in first 5 d of life when caused by gonorrhea (shorter incubation period) and 3-14 d of life when caused by chlamydia (longer incubation period)
- newborn prophylaxis with 0.5% erythromycin ointment- this is no longer recommended by ophthalmologists; however, it is still prescribed at some institutions
- chlamydia causes trachoma and inclusion conjunctivitis (different serotypes)

### Trachoma
- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva and later palpebral scarring (Arlt's line)

### Treatment
- oral azithromycin and topical tetracycline
- IV ceftriaxone often given in the emergency department

### Inclusion Conjunctivitis
- chronic conjunctivitis with follicles and subepithelial infiltrates
- most common cause of conjunctivitis in newborns
- newborn prophylaxis with 0.5% erythromycin ointment no longer recommended

### Treatment
- oral azithromycin, tetracycline, doxycycline

- Enlarged lymph nodes suggest infectious etiology, especially viral or chlamydial conjunctivitis
- Temporal conjunctival lymphatics drain to preauricular nodes, and nasal to submandibular nodes

**Preventing Ophthalmia Neonatorum**
Paediatr Child Health 2015;20(2):93-96
The use of silver nitrate as prophylaxis for neonatal ophthalmia was instituted in the late 1800s to prevent the devastating effects of neonatal ocular infection with *Neisseria gonorrhoeae*. At that time – during the preantibiotic era – many countries made such prophylaxis mandatory by law. Today, neonatal gonococcal ophthalmia is rare in Canada, but ocular prophylaxis for this condition remains mandatory in some provinces/territories.
Silver nitrate drops are no longer available and erythromycin, the only ophthalmic antibiotic eye ointment currently available for use in newborns, is of questionable efficacy. Ocular prophylaxis is not effective in preventing chlamydial conjunctivitis. Applying medication to the eyes of newborns may result in mild eye irritation and has been perceived by some parents as interfering with mother-infant bonding. Physicians caring for newborns should advocate for rescinding mandatory ocular prophylaxis laws. More effective means of preventing ophthalmia neonatorum include screening all pregnant women for gonorrhea and chlamydia infection, and treatment and follow-up of those found to be infected. Mothers who were not screened should be tested at delivery. Infants of mothers with untreated gonococcal infection at delivery should receive ceftriaxone. Infants exposed to chlamydia at delivery should be followed closely for signs of infection.

# Sclera

- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

# Episcleritis

### Definition
- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

### Etiology
- mostly idiopathic
- associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, and syphilis), inflammatory bowel disease, rosacea, and atopy

### Clinical Features
- may have discomfort and pain associated with red eye (often interpalpebral)
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial vessels)

### Treatment
- generally self-limited, recurrent in 2/3 of cases
- topical steroid
- oral NSAIDs

To differentiate between episcleritis and scleritis, place a drop of phenylephrine 2.5% (Mydfrin®; AK-Dilate®) in the affected eye. Re-examine the vascular pattern 10-15 min later; in episcleritis the episcleral vessels should blanch with phenylephrine

# Scleritis

- usually unilateral: can be classified as anterior or posterior and diffuse, nodular, necrotizing with inflammation, or necrotizing without inflammation (scleromalacia perforans)
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly

### Etiology
- may be a manifestation of systemic disease
- collagen vascular disease, e.g. SLE, RA, GPC, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. gout, thyrotoxicosis
- infectious, e.g. *S. aureus, S. pneumoniae, P. aeruginosa*, herpes zoster
- chemical or physical agents, e.g. thermal, alkali, or acid burns
- idiopathic

### Clinical Features
- severe "deep" or "boring" pain, photophobia, red eye, decreased vision
- pain is the best indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels
- may have anterior chamber cells and flare, corneal infiltrate, scleral thinning, scleral edema
- sclera may have a purple or "violaceous" hue (best seen in natural light), due to thinning of scleral fibres exposing the bluish-coloured uvea
- failure to blanch with topical phenylephrine

**Scleromalacia Perforans**
- Asymptomatic anterior necrotizing scleritis without inflammation
- Strongly associated with RA
- May result in scleral thinning
- Traumatic perforation can easily occur – examine eye very gently

### Treatment
- **vision threatening** – needs to be referred to ophthalmology
- life threatening- indicator of poor systemic disease control with an increased 5 yr mortality rate (not from scleritis) without treatment of underlying untreated or unrecognized autoimmune condition
- systemic NSAIDs, systemic steroid, and systemic immunomodulation
- treat underlying etiology

## Cornea

- function
  - transmission of light
  - refraction of light (2/3 of total refractive power of eye)
  - barrier against infection, foreign bodies
- transparency due to avascularity, uniform collagen structure and deturgescence (relative dehydration)
- 5 layers (anterior to posterior): epithelium, Bowman's layer, stroma, Descemet's membrane, and the endothelium (dehydrates the cornea; dysfunction leads to corneal edema). Some have argued the existence of a 6th layer, "Dua's layer", although it is debated if this is a truly unique and additional layer
- extensive sensory fibre network (V1 distribution); therefore, abrasions are very painful

**Learn the Layers of the Cornea**
**ABCDE**
**A**nterior epithelium
**B**owman's Membrane
**C**orneal Stroma
**D**ua's Layer, Descemet's Membrane
**E**ndothelium

## Foreign Body

### Definition
- foreign material in or on cornea

### Clinical Features
- patients may note pain, tearing, photophobia, foreign body sensation, and red eye
- signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, and anterior chamber cells/flare
- may have associated rust ring if metallic

Foreign body behind lid may cause multiple vertical corneal epithelial abrasions due to blinking

### Complications
- abrasion, infection, ulcer, scarring, rust ring, secondary iritis

Topical analgesics should only be used to facilitate examination. They should NEVER be used as treatment for any ocular problem

### Treatment
- remove under magnification using local anesthetic and sterile needle or refer to ophthalmology for removal under magnification (depending on depth and location)
- treat as per corneal abrasion

## Corneal Abrasion

### Definition
- epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

### Clinical Features (Table 7)
- pain, redness, tearing, photophobia, foreign body sensation
- de-epithelialized area stains with fluorescein dye
- pain relieved with topical anesthetic (DO NOT use for treatment- risk of corneal melt or infection)

Corneal abrasions from organic matter (e.g. twig, finger nail, etc.) have higher recurrence, even years later

### Complications
- infection, ulceration, recurrent erosion, secondary iritis

### Treatment
- topical antibiotic (drops or ointment), abrasion from organic material should be covered against *Pseudomonas*
- consider topical NSAIDs (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch (do not patch non-contact lens wearers as can precipitate infection)
- most abrasions clear spontaneously within 24-48 h

**Patching for Corneal Abrasion**
Cochrane Database Syst Rev 2016; 7:CD004764.
**Results:** 12 RCTs/Quasi-RCTs identified, n=1080. At 24 hours: people receiving patch were less likely to have a healed abrasion (RR 0.89, 95% CI 0.79-1.00). At 48 hours: similar effect for both groups (RR 0.97, 95% CI 0.91-1.02). At 72 hours: similar effect for both groups (RR 1.01, 95% CI 0.97-1.05)
**Summary:** Certainty of evidence is moderate to low; more research is needed with better quality trials to examine effectiveness of patching for large abrasions. Participants with patch were more likely to receive additional adjuvant treatment and took slightly longer to heal, but the difference was small and possibly clinically insignificant.

## Recurrent Erosions

### Definition
- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

### Etiology
- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

### Treatment
- same as corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 6-12 mo, topical lubrication
- bandage contact lens, anterior stromal puncture, superficial keratectomy with diamond burr polishing, or phototherapeutic keratectomy for chronic recurrences

## Corneal Ulcer

### Etiology
- local necrosis of corneal tissue due to infection
  - infection is usually bacterial; rarely viral, fungal, or protozoan (*Acanthamoeba*)
- secondary to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

### Clinical Features
- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

### Complications
- decreased vision, corneal perforation, iritis, endophthalmitis

### Investigations
- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leakage will dilute the green stain at site of wound

### Treatment
- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

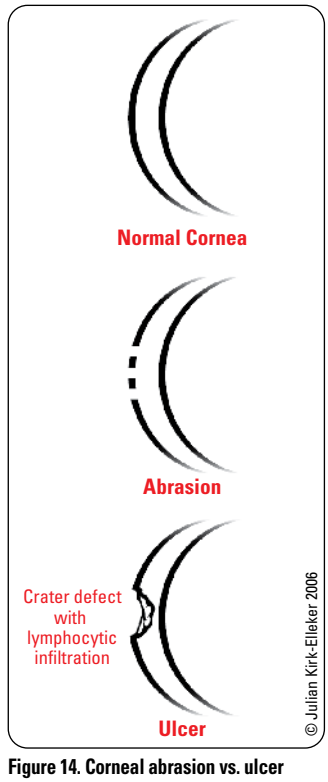

Figure 14. Corneal abrasion vs. ulcer

**Table 7. Corneal Abrasion vs. Corneal Ulcer**

| | Abrasion | Ulcer |
|---|---|---|
| **Time Course** | Acute (instantaneous) | Subacute (days) |
| **History of Trauma** | Commonly | Rare |
| **Cornea** | Clear | White, necrotic area |
| **Iris Detail** | Clear | Obscured |
| **Corneal Thickness** | Normal | May have crater defect/thinning |
| **Extent of Lesion** | Limited to epithelium | Extension into stroma |

**Abrasion vs. Ulcer on Slit-Lamp**
An abrasion appears clear while an ulcer is more opaque

# Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers)
- may be triggered by stress, fever, sun exposure, and immunosuppression

### Clinical Features
- pain, tearing, foreign body sensation, red eye, may have decreased vision, and eyelid edema
- corneal hypoesthesia
- classic form of HSV infectious epithelial keratitis is a dendritic (thin and branching) lesion with terminal end bulbs in epithelium that stains with fluorescein
- HSV may cause other forms of infectious epithelial keratitis, as well as stromal keratitis (which may be infectious or immune-mediated), and endotheliitis (presumably immune-mediated but possible role of live virus)

Steroid treatment for ocular disorders should only be prescribed and supervised by an ophthalmologist, as they can impair corneal healing, exacerbate herpetic keratitis, and elevate IOP

### Complications
- corneal scarring (can lead to loss of vision)
- chronic interstitial keratitis due to penetration of virus into stroma
- secondary iritis, secondary glaucoma

### Treatment
- topical antiviral such as trifluridine, or systemic antiviral such as acyclovir
- debridement of dendrite
- no steroids initially – may exacerbate condition
- ophthalmologist must exercise caution if adding topical steroids for stromal keratitis, endotheliitis or iritis, and patients covered with antiviral prophylaxis

# Herpes Zoster Ophthalmicus

### Definition
- dermatitis in the dermatomal distribution of CN V1 that is typically unilateral and respects the midline
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then globe will be involved in ~75% of cases
- if no nasal involvement, eye is involved in 1/3 of patients

### Clinical Features
- pain, tearing, photophobia, red eye
- corneal edema, pseudodendrite, SPK
- corneal hypoesthesia

### Complications
- keratitis, ulceration, perforation, and scarring
- secondary iritis, secondary glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

### Treatment
- oral antiviral (acyclovir, valcyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for immune-mediated keratitis, iritis
- erythromycin ointment if conjunctival involvement

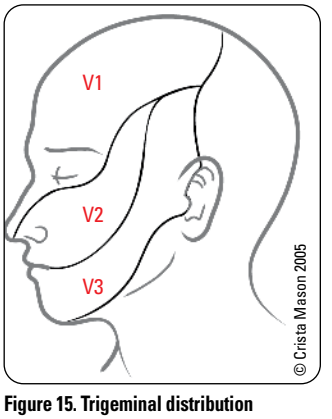

**Figure 15. Trigeminal distribution**

# Keratoconus

### Definition
- bilateral (often asymmetric) thinning and bulging (ectasia) of the cornea resulting in a conical shape
- usually sporadic but can be associated with Down syndrome, atopy, contact lens use, and vigorous eye rubbing
- associated with breaks in Descemet's membrane and Bowman's layer
- results in decreased vision from irregular astigmatism, scarring, and stromal edema

To detect keratoconus, look for bulging of the lower eyelid when the patient looks downward (Munson's sign)

### Treatment
- attempt correction with spectacles and/or rigid gas permeable contact lens
- corneal collagen cross-linking treatment to halt disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty or deep anterior lamellar keratoplasty (partial-thickness corneal transplant) as last resort

# Arcus Senilis

- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, complications or treatment necessary

## Kayser-Fleischer Ring

- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease

# The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

## Uveitis

- uveal inflammation which may involve one, two, or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, and malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

**Table 8. Anatomic Classification of Uveitis**

| | Anterior Uveitis (Iritis) | Intermediate Uveitis | Posterior Uveitis |
|---|---|---|---|
| **Location** | Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis<br>Usually unilateral | The vitreous is the major site of the inflammation | Inflammation of the choroid and/or retina |
| **Etiology** | Usually idiopathic<br>Connective tissue diseases:<br>HLA-B27: reactive arthritis, ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease<br>Non-HLA-B27: juvenile idiopathic arthritis<br>Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster<br>Other: sarcoidosis, trauma, large abrasion, and postocular surgery | Mostly idiopathic, secondary causes include sarcoidosis, Lyme disease, and multiple sclerosis | Bacterial: syphilis, tuberculosis<br>Viral: herpes simplex virus, CMV in AIDS<br>Fungal: histoplasmosis, candidiasis<br>Parasitic: toxoplasmosis (most common cause), toxocara<br>Immunosuppression may predispose to any of the above infections<br>Autoimmune: Behçet's disease (triad of oral ulcers, genital ulcers, and posterior uveitis)<br>Malignancies (masquerade syndrome): metastatic lesions, malignant melanoma, lymphoma |
| **Clinical Features** | Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA, lacrimation<br>Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle)<br>Anterior chamber "cells" (WBC in anterior chamber due to anterior segment inflammation) and "flare" (protein precipitates in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic exudates inferiorly in the anterior chamber)<br>Occasionally keratic precipitates (clumps of cells on corneal endothelium)<br>Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis or iritis from herpes simplex and zoster may cause inflammatory glaucoma (trabeculitis) | Insidious onset of blurred vision, accompanied by vitreous floaters<br>Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric<br>Associated with anterior uveitis, most severe cases of secondary intermediate uveitis<br>Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells)<br>Posterior segment 'snowbank' = grey-white fibrovascular plaque at the pars plana | Painless<br>Often no conjunctival or scleral injection present<br>Decreased VA<br>Floaters (debris and inflammatory cells)<br>Vitreous cells and opacities<br>Hypopyon formation |
| **Complications** | Inflammatory glaucoma<br>Posterior synechiae<br>Adhesions of posterior iris to anterior lens capsule<br>Indicated by an irregularly shaped pupil<br>If occurs 360°, can lead to angle closure glaucoma<br>Peripheral anterior synechiae (rare): adhesions of iris to cornea → secondary angle closure glaucoma<br>Cataracts<br>Band keratopathy (with chronic iritis)<br>Superficial corneal calcification keratopathy<br>Macular edema with chronic iritis | Cystoid macular edema (30% of cases), cataract, and glaucoma | Macular edema<br>Vitritis<br>Neovascularization<br>Visual field loss/scotoma |
| **Treatment** | Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm<br>Steroids: topical, sub-tenon, or systemic<br>Systemic analgesia<br>If recurrent episodes, extensive medical workup may be indicated to rule out secondary causes | Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents<br>Vitrectomy, cryotherapy, or laser photocoagulation to the "snowbank" | Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss)<br>Vitreous biopsy if suspected masquerade/malignancy |

# Lens

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

## Cataracts

### Definition
- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, and posterior subcapsular

### Etiology
- acquired
  - age-related (over 90% of all cataracts)
  - cataract associated with systemic disease (may have juvenile onset)
    - DM
    - metabolic disorders (e.g. Wilson's disease, galactosemia, or homocystinuria)
    - hypocalcemia
  - traumatic (may be rosette-shaped)
  - intraocular inflammation (e.g. uveitis)
  - toxic (steroids, phenothiazines)
  - radiation
- congenital
  - high myopia
  - present with altered red reflex or leukocoria
  - treat promptly to prevent amblyopia

### Clinical Features
- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
  - patient may read without previously needed reading glasses
- diagnosis by slit-lamp exam
- may impair view of retina during fundoscopy

### Treatment
- medical: no role for medical management
- surgical: definitive treatment
  - indications for surgery
    - to improve visual function in patients whose vision loss leads to functional impairment
    - to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
    - congenital or traumatic cataracts
  - phacoemulsification (phaco = lens)
    - most commonly used surgical technique
    - post-operative complications: RD, endophthalmitis, dislocated IOL, macular edema, glaucoma, posterior capsular opacification

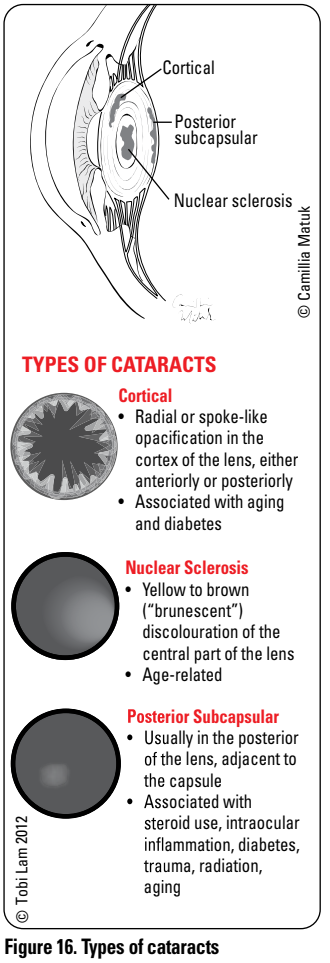

**Figure 16. Types of cataracts**

## Dislocated Lens (Ectopia Lentis)

### Etiology
- associated with Marfan's Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic

### Clinical Features
- decreased VA
- may get monocular diplopia
- iridodenesis (quivering of iris with movement)
- phacodonesis (observed movement of the lens)
- direct ophthalmoscopy may elicit abnormal red reflex

### Complications
- cataract, glaucoma, uveitis

### Treatment
- surgical lens replacement

# Vitreous

- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

## Posterior Vitreous Detachment

### Etiology
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

### Clinical Features
- floaters, flashes of light

### Complications
- traction at sites of firm adhesion may result in retinal tear with or without subsequent rhegmatogenous retinal detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

### Treatment
- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

**Weiss Ring**: formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

**Floaters**: "bugs", "cobwebs", or "spots" of vitreous condensation that move with eye position

Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment

## Vitreous Hemorrhage

### Definition
- bleeding into the vitreous cavity

### Etiology
- PDR
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

### Clinical Features
- sudden loss of VA
- may be preceded by "shower" of many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

### Treatment
- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no RD), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser to possible bleeding sites/vessels

Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse

## Endophthalmitis and Vitritis

### Definition
- intraocular infection: acute, subacute, or chronic

### Etiology
- most commonly as post-operative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

Remember to inquire about tetanus status in post-traumatic endophthalmitis

### Clinical Features
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

### Treatment (see *Ocular Trauma*, OP40)
- **OCULAR EMERGENCY**: presenting vision best indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

# Retina

- composed of two parts (Figure 2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
  - retinal pigmented epithelium layer: external to neurosensory retina
- macula: rich in cones (for colour vision); most sensitive area of retina (Figure 17)
- fovea: centre of macula; responsible for detail, fine vision, lacks retinal vessels
- optic disc: collection of retinal nerve fibre layers forming optic nerve (CNII)
- ora serrata: irregularly-shaped, anterior margin of the retina (cannot be visualized with direct ophthalmoscope)

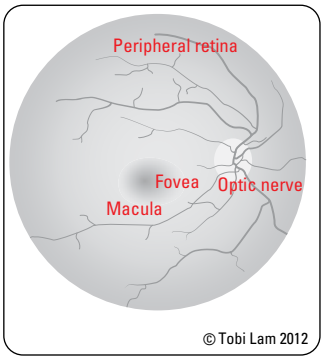

**Figure 17. Retina**

## Central/Branch Retinal Artery Occlusion

### Etiology

- occlusion of blood flow from following causes results in loss of vision due to oxygen starvation of the retinal tissues and eventual cell death
  - emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
  - thrombus
  - temporal arteritis

### Clinical Features

- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)
- fundoscopy
  - "cherry-red spot"
  - retinal pallor
  - cotton wool spots (retinal infarcts)
  - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations

### Treatment

- **OCULAR EMERGENCY:** attempt to restore blood flow within 2 h (irreversible retinal damage if >90 min of complete CRAO)
- massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
- decrease IOP
  - topical β-blockers
  - IV acetazolamide
  - IV mannitol (draws fluid from eye)
  - drain aqueous fluid – anterior chamber paracentesis (carries risk of infection, lens puncture)
- YAG laser embolectomy
- intra-arterial or intravenous thrombolysis
- hyperbaric oxygen therapy

**Hallmark of CRAO**
"Cherry-red spot" located at centre of macula (visualization of unaffected highly vascular choroid through the thin fovea)

Treatment for a central retinal artery occlusion (CRAO) must be initiated within 2 h of symptom onset for any hope of restoring vision

The "blood and thunder" appearance on fundoscopy is very specific for CRVO

There is an 8-10% risk of developing CRVO or BRVO in other eye

**Effect of Bevacizumab vs. Aflibercept on Visual Acuity Among Patients With Macular Edema Due to Central Retinal Vein Occlusion – The SCORE2 Randomized Clinical Trial**
JAMA 2017;317(20):2072-2087
**Objective**: To investigate whether bevacizumab (used off-label) is non-inferior to aflibercept for the treatment of macular edema secondary to central retinal or hemiretinal vein occlusion
**Study**: Randomized clinical trial
**Patients**: 362 patients with macular edema due to central retinal or hemiretinal vein occlusion
**Results**: At month 6, the mean visual acuity letter score (VALS) was 69.3 (a mean increase from baseline of 18.6) in the bevacizumab group and 69.3 (a mean increase from baseline of 18.9) in the aflibercept group (P = .001 for noninferiority). Adverse events were rare but were similar between the two groups.
**Conclusion**: After 6 mo of treatment, bevacizumab was non-inferior to aflibercept with respect to visual acuity. Cost differences between the drugs has important economic implications.

## Central/Branch Retinal Vein Occlusion

### Etiology

- second most frequent "vascular" retinal disorder after DR
- exact cause is not known; possible arteriosclerotic changes in the central retinal artery transform the artery into a rigid structure and impinge upon the central retinal vein as they share a common sheath
- predisposing factors: atherosclerotic vascular disease, HTN, DM, glaucoma, hyperviscosity (e.g. sickle cell disease, polycythemia rubra vera, lymphoma, leukemia), drugs (e.g. oral contraceptive pill, diuretics)

### Clinical Features

- painless, monocular, gradual, or sudden vision loss
- ± RAPD
- fundoscopy
  - "blood and thunder" appearance
  - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA ~20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula intact

**Intravitreal Aflibercet injection for Macular Edema Resulting from Central Retinal Vein Occlusion: One Year results of Phase 3 GALILEO study**
Ophthalmology 2014; 121(1) 202-8
Treatment with intravitreal aflibercept provided significant functional and anatomic benefits after 52 weeks as compared with sham. The improvement achieved after 6 monthly doses at week 24 were maintained until week 52 with prn dosing.

- hemorrhagic/ischemic retinopathy
  - usually older patient with deficient arterial supply
  - RAPD, VA ~20/200, reduced peripheral vision
  - more hemorrhages, cotton wool spots, congestion
  - poor visual prognosis

### Complications
- neovascularization of retina and iris (secondary rubeosis), leading to secondary glaucoma
- vitreous hemorrhage
- macular edema

### Treatment
- treatment available for complications of CRVO/BRVO, including retinal laser photocoagulation, anti-VEGF and/or corticosteroid injection

**Efficacy and Safety of Widely Used Treatments for Macular Edema Secondary to Retinal Vein Occlusion: A Systematic Review**
BMC Ophthalmol 2014;14:17
**Purpose**: To assess the efficacy of widely used treatments for macular edema (ME) secondary to retinal vein occlusion (RVO). ME secondary to RVO can cause vision loss due to blockage of the central retinal vein (CRVO) or a branch retinal vein (BRVO).
**Outcomes**: Mean change in best-corrected visual acuity (BCVA) from baseline and/or number of patients gaining at least 10 letters from baseline to 6 mo or equivalent time point.
**Results**: 14 unique RCTs identified. Ranibizumab 0.5 mg produced greater improvements in BCVA at 6 mo compared to sham in BRVO (mean difference 11 letters; 95% CI 7.83-14.17) and CRVO (mean difference 14 letters; 95% CI 10.51-17.69). Improvements in BCVA were also observed with dexamethasone intravitreal implant (IVT) 0.7 mg compared with sham in patients with BRVO or CRVO (mean difference 2.5 letters; 95% CI 0.7-4.3). The difference was significant with BRVO alone, but not CRVO alone. At 36 mo in a large prospective RCT, a greater proportion of patients with BRVO gained >15 letters with laser therapy versus no treatment (OR 3.16; 95% CI 1.25-8.00), whereas no difference was observed in a 9 mo endpoint smaller study. Three studies showed no benefit for laser therapy in CRVO.
**Conclusions**: Both ranibizumab and dexamethasone IVT show significant improvements over previously accepted standard of care (laser therapy) for the treatment of BRVO and CRVO.

Superotemporal retina is the most common site for horseshoe tears

# Retinal Detachment

### Definition
- cleavage in the plane between the neurosensory retina and the RPE
- three types
  - rhegmatogenous (most common)
    - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tears may be caused by PVD, degenerative retinal changes, trauma, or iatrogenically
    - incidence increases with advancing age, in high myopes, and after ocular surgery/trauma
  - tractional
    - caused by vitreal, epiretinal, or subretinal membrane pulling the neurosensory retina away from the underlying RPE
    - found in conditions such as DR, RVO, sickle cell disease, ROP, and ocular trauma
  - exudative
    - caused by vascular transudation of fluid or damage to the RPE resulting in fluid accumulation in the subretinal space
    - main causes are intraocular tumour, posterior uveitis, central serous retinopathy

### Clinical Features
- sudden onset
- flashes of light
  - due to mechanical stimulation of the retinal photoreceptors
- floaters
- hazy spots in the line of vision which move with eye position
  - due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/peripheral field loss
  - darkness in one field of vision when the retina detaches in that area
- loss of central vision (if macula "off")
- decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
- ophthalmoscopy: detached retina is grey-white from retinal edema, and loss of red reflex
- ± RAPD

### Treatment
- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy
- therapeutic:
  - rhegmatogenous
    - scleral buckle procedure
    - pneumatic retinopexy
    - vitrectomy plus injection of gas (injection of silicone oil in cases of recurrent detachment)
  - tractional
    - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
  - exudative
    - management is nonsurgical; any underlying disease should be treated if possible

### Complications
- loss of vision, vitreous hemorrhage, recurrent RD
- RD is an emergency, especially if the macula is still attached (macula "on")
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

# Retinitis Pigmentosa

### Definition
- hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy
- many forms of inheritance, most commonly autosomal recessive (60%)

### Clinical Features
- night blindness, decreased peripheral vision ("tunnel vision"), decreased central vision (macular changes), glare (from posterior subcapsular cataracts, common)

### Investigations
- fundoscopy: areas of "bone-spicule" pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
- electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

### Treatment
- gene treatments have the potential to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients
- 3 independent clinical studies have shown safe and effective human gene therapy with rAAV2-vector for RPE65 in the treatment of Leber congenital amaurosis

**Retinitis Pigmentosa Inherited Forms**
- Autosomal recessive: most common
- Autosomal dominant: best prognosis
- X-linked: worst prognosis

**Triad of Retinitis Pigmentosa**
**APO**
**A**rteriolar narrowing
**P**erivascular bony-spicule pigmentation
**O**ptic disc pallor

## Age-Related Macular Degeneration

### Definition
- leading cause of irreversible blindness in the Western world, associated with increasing age, usually bilateral but asymmetric

### Classification
- **Non-Exudative/"Dry" (Non-Neovascular) AMD**
  - most common type of AMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow-white deposits between the RPE and Bruch's membrane (area separating inner choroidal vessels from RPE)
  - geographic RPE atrophy: coalescence of RPE atrophy, clumps of focal hyperpigmentation or hypopigmentation
  - may progress to neovascular AMD

- **Exudative/"Wet" (Neovascular) AMD**
  - 10% of AMD, but 80% of AMD that results in severe vision loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch's membrane causing subsequent growth and proliferation of new, fine choroidal vessels
  - may lead to serous detachment of overlying RPE and retina, hemorrhage, and lipid precipitates into the subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of subretinal fibrovascular proliferation progresses to disciform scarring and severe central vision loss

### Risk Factors
- female
- increasing age
- family history
- smoking
- Caucasian race
- blue irides

### Clinical Features
- variable degree of progressive central vision loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

### Investigations
- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- Fluorescein angiography: assess type and location of choroidal neovascularization – pathologic new vessels leak dye
- OCT retinal imaging: assess the amount of intraretinal and subretinal exudation

### Treatment
- non-neovascular "dry" AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study 2 (AREDS2) in sidebar
- neovascular "wet" AMD
  - see *Common Medications*, OP42
  - intravitreal injection of anti-VEGF
    - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®), aflibercept (Eylea®) (see *VEGF Inhibitors*, OP43)
  - no definitive treatment for disciform scarring
  - photodynamic therapy with verteporfin (Visudyne®)
    - IV injection of verteporfin, followed by low-intensity laser to area of choroidal neovascularization

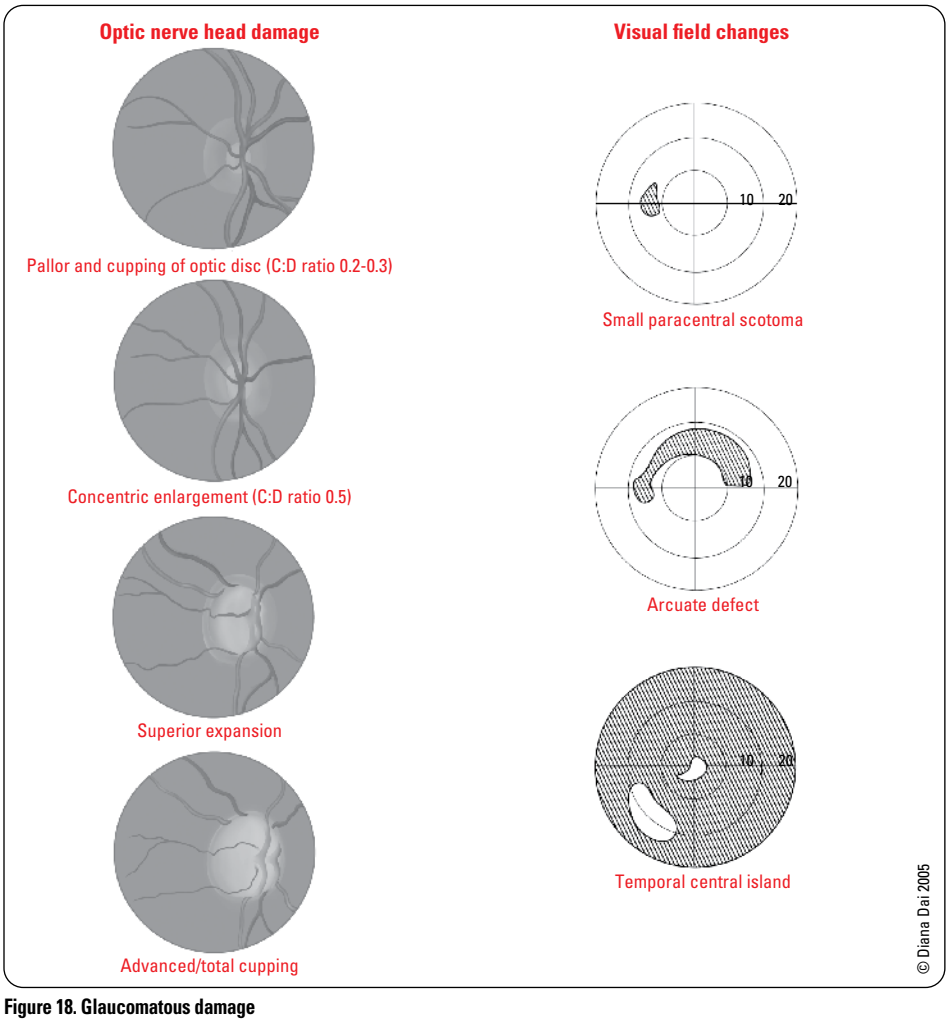
**Age-Related Eye Disease Study 2 (AREDS2) Lutein + zeaxanthin and omega-3 fatty acids for AMD: the Age-Related Eye Disease Study 2 (AREDS2) randomized clinical trial.**
Jama 2013; 309(19):2005-15
The original AREDS formulation contains vitamin C, E and β-carotene, zinc and copper; reduced risk of progression to advanced AMD by 2%. Addition of lutein+zeaxanthin, DHA/EPA, or both to the AREDS formulation in primary analyses didn't reduce risk of progression to advance AMD. However, because of the potential increased incidence of lung cancer in former smokers, lutein+zeaxanthin could be an appropriate carotenoid substitute in the AREDS formulation.

# Glaucoma

## Definition
- progressive, pressure-sensitive, optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

## Background
- aqueous is produced by the ciliary body and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm
- an isolated increase in IOP is termed ocular hypertension (OHT) - should be followed for increased risk of developing glaucoma
- pressures >21 mmHg increase the risk of developing glaucoma
- loss of peripheral vision most commonly precedes central vision loss
- structural changes commonly precede functional changes

## Investigations
- VA testing
- slit-lamp exam to assess anterior chamber depth; gonioscopy to assess angle patency
- ophthalmoscopy to assess the disc features
- tonometry to measure IOP
- visual field testing
- pachymetry to measure corneal thickness
- OCT of the nerve fibre layer (NFL) at the optic nerve to monitor for loss of NFL
- follow-up includes optic disc examination, IOP measurement, OCT of the optic nerve and visual field testing to monitor course of disease



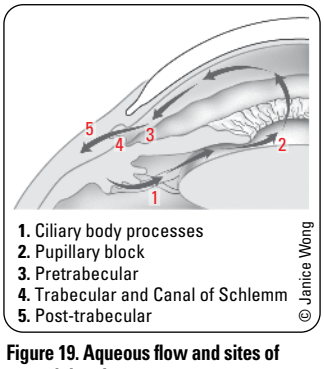


**Figure 18. Glaucomatous damage**

**Ten Year Follow-Up of Age-Related Macular Degeneration in the Age-Related Eye Disease Study: AREDS Report No. 36**
JAMA Ophthalmol 2014;132(3):272-7
**Study**: Randomized clinical trial.
**Objective**: To describe 10 yr progression rates to intermediate or advanced AMD.
**Patients**: Age-related eye disease study (AREDS) participants were observed for an additional 5 yr after RCT completion. Participants aged 55-80 yr with no AMD or AMD of varying severity (n = 4757) were followed up in the AREDS trial for a median duration of 6.5 yr. When the trial ended, 3549 of the 4203 surviving participants were followed for 5 additional yr.
**Intervention**: Treatment with antioxidant vitamins and minerals.
**Main Outcome**: Development of varying stages of AMD and changes in visual acuity.
**Results**: The risk of progression to advanced AMD increased with increasing age (p=0.01) and severity of drusen. Women (p=0.005) and current smokers (p<0.001) were at increased risk of neovascular AMD. In the oldest participants with the most severe AMD status at baseline, the risks of developing neovascular AMD and central geographic atrophy by 10 yr were 48.1% and 26.0%, respectively. Similarly, rates of progression to large drusen increased with increasing severity of drusen at baseline, with 70.9% of participants with bilateral medium drusen progressing to large drusen and 13.8% to advanced AMD in 10 yr. Median visual acuity at 10 yr in eyes that had large drusen at baseline but never developed advanced AMD was 20/25; eyes that developed advanced AMD had a median visual acuity of 20/200.
**Conclusion**: The natural history of AMD demonstrates relentless loss of vision in persons who developed advanced AMD.

Average IOP: 15 ± 3 mmHg
Normal C:D : ≤0.4
Suspect glaucoma if C:D ratio >0.6, C:D ratio differs between eyes by >0.2, or cup approaches disc margin

**1.** Ciliary body processes
**2.** Pupillary block
**3.** Pretrabecular
**4.** Trabecular and Canal of Schlemm
**5.** Post-trabecular

**Figure 19. Aqueous flow and sites of potential resistance**

# Primary Open-Angle Glaucoma

## Definition
- most common form, >95% of all glaucoma cases
- unobstructed open-angle, resistance is within the trabecular meshwork
- insidious and asymptomatic, screening is critical for early detection

## Major Risk Factors
- ocular hypertension (IOP >21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic
- thin central cornea (OHTS trial)

## Minor Risk Factors
- myopia
- HTN
- DM
- hyperthyroidism (Graves' disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

## Clinical Features
- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased C:D ratio (vertical C:D >0.6)
  - significant C:D asymmetry between eyes (>0.2 difference)
  - thinning, notching of the neuroretinal rim
  - flame shaped disc hemorrhage
  - 360° of peripapillary atrophy
  - nerve fibre layer defect
  - large vessels become nasally displaced
- visual field loss
- slow, progressive, irreversible loss of peripheral vision
- paracentral defects, arcuate scotoma, and nasal step are characteristics (Figure 18)
- late loss of central vision if untreated

## Treatment
- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see *Glaucoma Medications*, Table 14, OP43)
  - increase aqueous outflow
    - topical prostaglandin analogues
    - topical α-adrenergics
    - topical cholinergics
  - decrease aqueous production
    - topical β-blockers
    - topical and oral carbonic anhydrase inhibitors
    - topical α-adrenergics
- laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
- trabeculectomy: creation of a new outflow tract from anterior chamber to under the conjunctiva forming a bleb
- minimally invasive glaucoma surgery (MIGS): implantation of IOP lowering drainage devices (e.g. iStent), high safety profile and generally for patients with mild to moderate glaucoma
- tube shunt: for advanced stages of glaucoma
- serial optic nerve head examinations, IOP measurements, OCT of optic nerve and visual field testing to monitor disease course

**Risk Factors for POAG**
**A FIAT**
**A**ge
**F**amily history
**I**OP
**A**frican descent
**T**hin cornea

**Open- and Closed-Angle Glaucoma**

| POAG | PACG |
|---|---|
| • Common (95%) | • Rare (5%) |
| • Chronic course | • Acute onset |
| • Painless eye without redness | • Painful red eye |
| • Moderately ↑ IOP | • Extremely ↑ IOP |
| • Normal cornea and pupil | • Hazy cornea |
| • No N/V | • Mid-dilated pupil unreactive to light |
| • No halos around light | • ± N/V, abdominal pain |
| | • Halos around light |

Elevated IOP is the only modifiable risk factor that has been proven to prevent progression of glaucoma. Treating patients with ocular hypertension but no signs of glaucoma has also shown to reduce the risk of developing glaucoma

**The Ocular Hypertension Treatment Study**
Arch Ophthalmol-Chic 2002;120:701-713
**Study**: Randomized clinical trial.
**Patients**: 1636 patients with no evidence of glaucomatous damage, aged 40-80 yr, and with IOP between 24-32 mmHg in one eye and between 21-32 mmHg in the other eye.
**Intervention**: Randomized to observation or treatment with commercially available topical ocular hypotensive medication.
**Main Outcome**: Development of visual field abnormality or optic disc deterioration attributed to POAG.
**Results**: Mean reduction in IOP in the medication group was 22.5% ± 9.9% vs. 4.0% ± 11.6% in the observation group. At 5 yr, the probability of developing POAG was 4.4% in the medication group and 9.5% in the observation group ($p<0.0001$).
**Conclusions**: Topical ocular hypotensive medication was effective in delaying or preventing the onset of POAG in individuals with elevated IOP.

# Normal Tension Glaucoma

## Definition
- POAG with IOP in normal range
- often found in women >60 yr, but may occur earlier
- associated with migraines, peripheral vasospasm, systemic nocturnal hypotension, sleep apnea
- damage to optic nerve may be due to vascular insufficiency

## Treatment
- treat reversible causes

# Secondary Open-Angle Glaucoma

## Etiology
- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork including:
  - steroid-induced glaucoma, traumatic glaucoma, pigmentary dispersion syndrome, pseudoexfoliation syndrome

**Rule of Fours**
1/4 of general population using topical steroid for 4 wk, 4x/d will develop an increase in IOP

# Primary Angle-Closure Glaucoma

## Definition
- 5% of all glaucoma cases
- peripheral iris bows forward obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block and results in impaired drainage, leading to a sudden rise in IOP

## Risk Factors
- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

## Clinical Features
- red, painful eye = **RED FLAG**
- unilateral, but other eye at increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

## Complications
- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synechiae, resulting in permanent angle closure

## Treatment
- **OCULAR EMERGENCY:** refer to ophthalmologist for acute angle-closure glaucoma
- medical treatment (see *Glaucoma Medications*, Table 14, OP43)
  - aqueous suppressants and hyperosmotic agents
  - miotic drops (pilocarpine) to reverse pupillary block
  - multiple topical IOP-lowering agents
  - hypserosmotic agents such as oral glycerine, or IV mannitol
- laser iridotomy is definitive

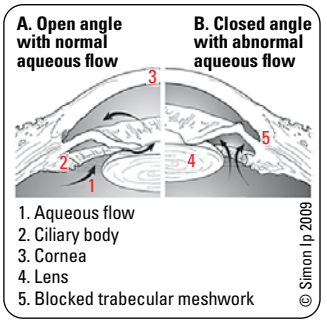

**Figure 20. Normal open-angle vs. angle-closure glaucoma**

**Angle-Closure Glaucoma**
**BACH**
Tx with miotics and β-**b**lockers
**A**drenergics
**C**holinergics
**H**yperosmotic agents

**Collaborative Normal Tension Glaucoma Study**
*Curr Opin Ophthalmol* 2003;14:86-90
Treatment aimed at lowering IOP by 30% in patients with normal tension glaucoma tends to reduce the rate of visual field loss. Due to variability in disease progression and a significant group that shows no visual field loss at 5 yr despite no treatment, further studies are needed to delineate which subgroups may benefit most from treatment.

# Secondary Angle-Closure Glaucoma

## Uveitis
- inflamed iris adheres to lens (posterior synechiae)

## Neovascular Glaucoma
- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris and angle vessels

# Pupils

- pupil size is determined by the balance between the sphincter muscle and the dilator muscle
- sphincter muscle is innervated by the parasympathetic nervous system carried by CN III
- dilator muscle is innervated by the sympathetic nervous system (SNS)
  - first-order neuron = hypothalamus → brainstem → spinal cord
  - second-order/preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
  - third-order/postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is norepinephrine
    - as a diagnostic test, 4-10% cocaine prevents the reuptake of norepinephrine, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner's Syndrome)
- see Neurology, Figure 8, N8

**5 Targets of Retinal Signals**
- Pretectal nucleus (pupillary reflex/eye movements)
- Lateral geniculate body of thalamus
- Superior colliculus (eye movements)
- Suprachiasmatic nucleus (optokinetic)
- Accessory optic system (circadian rhythm)

# Pupillary Light Reflex

- light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
- impulses enter bilaterally in midbrain via pretectal area and Edinger-Westphal nuclei
- nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes

α1 – Pupillary dilator muscle contraction (mydriasis)
β2 – Ciliary muscle relaxation (non-accommodation); increased aqueous humour production
M3 – Pupillary sphincter contraction (miosis); increased ciliary muscle contraction (Accommodation)

# Pupil Abnormalities

### Denervation Hypersensitivity
- when postganglionic fibres are damaged, the under-stimulated end-organ attempts to compensate by developing an increase of neuroreceptors and becomes hypersensitive
- postganglionic parasympathetic lesions (i.e. Adie's pupil)
  - pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
- postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner's syndrome)
  - pupil will dilate with 0.125% epinephrine, normal pupil will not

### Local Disorders of Iris
- posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
- ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
- trauma (e.g. post-intraocular surgery)

### Anisocoria
- unequal pupil size
- idiopathic/physiologic anisocoria
  - 20% of population
  - round, regular, <1 mm difference
  - pupils reactive to light and accommodation
  - responds normally to mydiatrics/miotics
  - post eye surgery, or extensive retinal laser treatment
- see Table 9 for other causes of anisocoria

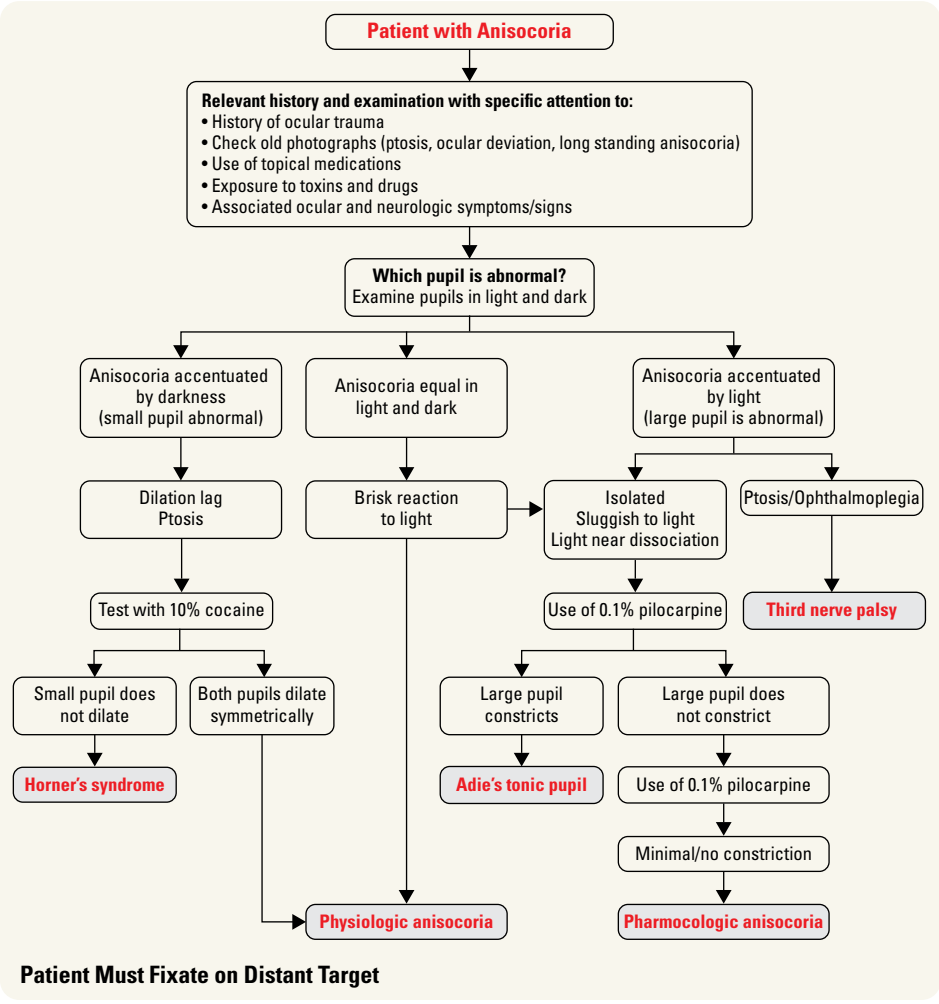

**Figure 21. Approach to anisocoria**

Reproduced with permission from: Kedar S, Biousse V, Newman NJ. Approach to the patient with anisocoria. In: UpToDate, Rose, BD (editor), UpToDate, Waltham, MA, 2011. Copyright 2011 UpToDate, Inc. For more information visit www.uptodate.com.

**Table 9. Summary of Conditions Causing Anisocoria**

| | Features | Site of Lesion | Light and Accommodation | Anisocoria | Mydriatics/ Miotics | Effect of Pilocarpine |
|---|---|---|---|---|---|---|
| **ABNORMAL MIOTIC PUPIL (impaired pupillary dilation)** | | | | | | |
| **Argyll-Robertson Pupil** | Irregular, usually bilateral | Midbrain | Poor in light; better to accommodation | | Dilates/ Constricts | |
| **Horner's Syndrome** | Round, unilateral, ptosis, anhydrosis, pseudoenophthalmos | Sympathetic system | Both brisk | Greater in dark | Dilates/ Constricts | |
| **ABNORMAL MYDRIATIC PUPIL (impaired pupillary constriction)** | | | | | | |
| **Adie's Tonic Pupil** | Irregular, larger in bright light | Ciliary ganglion | Poor in light, better to accommodation | Greater in light | Dilates/ Constricts | Constricts (hypersensitivity to dilute pilocarpine) |
| **CN III Palsy** | Round | Superficial CN III | ± fixed (acutely) at 7-9 mm | Greater in light | Dilates/ Constricts | Constricts |
| **Mydriatic Pupil** | Round, uni- or bilateral | Iris sphincter | Fixed at 7-8 mm | Greater in light | No effect | Will not constrict |

# Dilated Pupil (Mydriasis)

### Sympathetic Stimulation
- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

### Parasympathetic Under-stimulation
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, DM (may spare pupil), trauma
  - both mydriatics and CN III palsy cause pupil dilation; however, pupils in CN III palsy will constrict briskly to pilocarpine, while pupils dilated from mydriatics will not

### Acute Angle-Closure Glaucoma
- fixed, mid-dilated pupil

### Adie's Tonic Pupil
- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
  - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie's pupils are smaller than unaffected eye

### Trauma
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

# Constricted Pupil (Miosis)

### Senile Miosis
- decreased sympathetic stimulation with age

### Parasympathetic Stimulation
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

### Horner's Syndrome
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis and anhydrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of norepinephrine) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates norepinephrine release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- now more commonly, topical apraclonidine 0.5%
- postganglionic lesions result in denervation hypersensitivity, which will cause pupil to dilate with 0.125% epinephrine, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumour, Pancoast tumour, goitre, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabes dorsalis, cervical vertebral fractures

### Iritis
- miotic pupil initially
- can become irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light

### Argyll-Robertson Pupil
- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

### Other Causes
- optic neuritis, retinal lesions

CN III palsy with pupillary involvement may be associated with a posterior communicating artery aneurysm

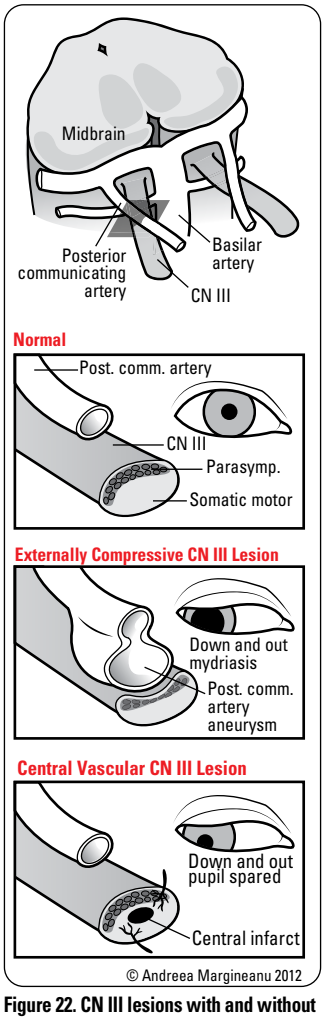

**Figure 22. CN III lesions with and without mydriasis**

**Horner's MAP**
**M**iosis
**A**nhydrosis
**P**tosis

# Relative Afferent Pupillary Defect

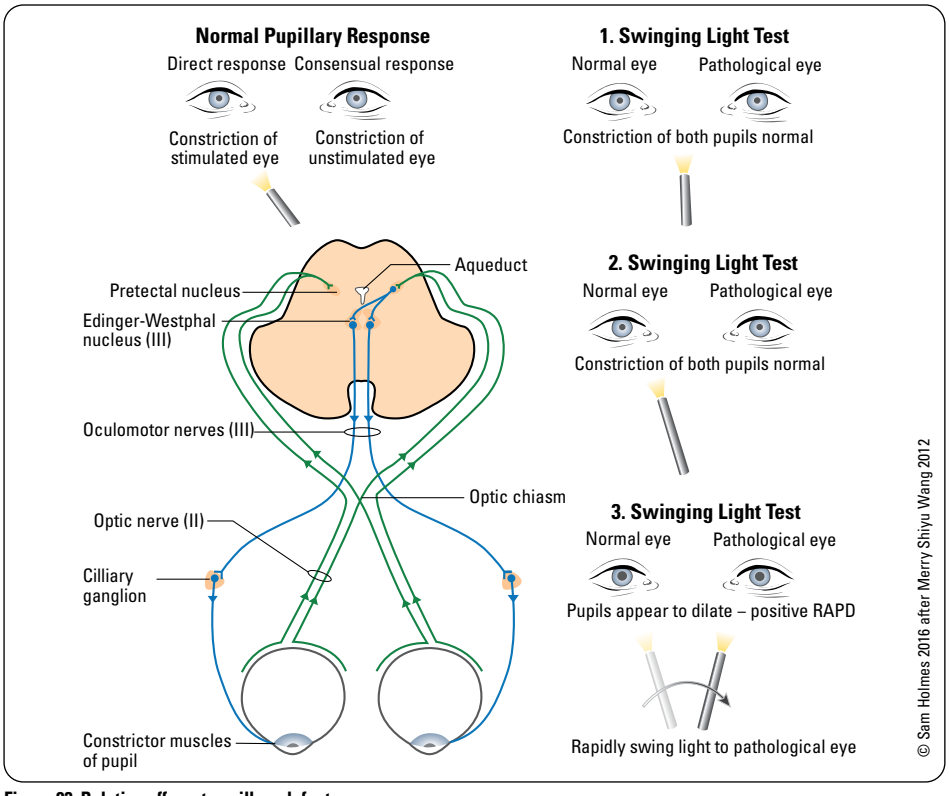

**Figure 23. Relative afferent pupillary defect**

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light caused by a lesion in visual afferent (sensory) pathway, anterior to optic chiasm
- differential diagnosis: large RD, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, **optic neuritis** (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
  - if the light is moved quickly from the unaffected eye to the affected eye, "paradoxical" dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye

Cataracts never produce a RAPD

It is possible to have RAPD and normal vision at the same time, e.g. in damaged superior colliculus caused by thalamic hemorrhage

Differentiate RAPD from physiologic pupillary athetosis ("hippus"), which is rapid, rhythmic fluctuations of the pupil, with equal amplitude in both eyes

# Malignancies

- uncommon site for 1° malignancies
- see *Retinoblastoma*, OP38

# Lid Carcinoma

## Etiology

- basal cell carcinoma (rodent ulcer) (90%)
  - spread via local invasion, rarely metastasizes
  - ulcerated centre, indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
  - spread via local invasion, may also spread to nodes and metastasize
  - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
  - often masquerades as chronic blepharitis or recurrent chalazion
  - highly invasive, metastasizes
- other: Kaposi's sarcoma, malignant melanoma, Merkel cell tumour, metastatic tumour

### Treatment
- incisional or excisional biopsies
- may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
- surgical reconstruction

## Uveal Melanoma

### Etiology
- most common 1° intraocular malignancy in adults
- more prevalent in Caucasians
- arise from uveal tract, 90% choroidal melanoma
- hepatic metastases predominate

### Clinical Features
- classic appearance of a pigmented dome-shaped mass extending from the ciliary body or the choroid
- diagnosis necessitates expertise of an ophthalmologist/ocular oncologist

### Treatment
- investigations: ocular ultrasound, fluorescent angiogram, OCT, and systemic cancer investigations
- depending on the size of the tumour, either radiotherapy (brachytherapy vs external beam), or enucleation

**To Find Small Ocular Melanoma**

**TFSOM**
**T** – **T**hickness >2 mm
**F** – Subretinal **F**luid
**S** – **S**ymptoms – vision changes
**O** – **O**range pigment
**M** – **M**argin within 3 mm of optic disc

## Metastases

- most common intraocular malignancy in adults
- most commonly from breast and lung in adults, neuroblastoma in children
- usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
- may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

### Treatment
- local radiation, chemotherapy
- enucleation if blind, painful eye

# Ocular Manifestations of Systemic Disease

## HIV/AIDS

- up to 75% of patients with AIDS have ocular manifestations

### External Ocular Signs
- Kaposi's sarcoma
  - secondary to human herpes virus 8 (HHV-8), causes bright red conjunctival lesion and subconjunctival hemorrhage
  - differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma
- multiple molluscum contagiosum
- herpes simplex/zoster keratitis

### Retina
- HIV retinopathy (most common)
  - cotton wool spots in >50% of HIV patients
  - intraretinal hemorrhage
- CMV retinitis
  - ocular opportunistic infection that develops when severely immunocompromised (CD4 count ≤50)
  - a necrotizing retinitis, with retinal hemorrhages and vasculitis, "brushfire" or "pizza pie" appearance
  - presents with scotoma (macular involvement and RD), blurred vision, and floaters
  - untreated infection will progress to other eye in 4-6 wk
  - treatment: virostatic agents (e.g. ganciclovir or foscarnet) via IV or intravitreal injection
- necrotizing retinitis
  - from herpes simplex virus, herpes zoster, toxoplasmosisdisseminated choroiditis
  - *Pneumocystis carinii* and *Mycobacterium avium intracellulare* can present with choroiditis
  - *Candida* can present as retinitis and vitritis

## Other Systemic Infections

- herpes zoster
  - see *Herpes Zoster*, OP18
- candidal endophthalmitis
  - fluffy, white-yellow, superficial retinal infiltrate that may eventually result in vitritis
  - may present with inflammation of the anterior chamber
  - treatment: systemic amphotericin B, oral fluconazole

- toxoplasmosis
  - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous infiltration (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by *Toxoplasma gondii* protozoa transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folinic acid, or clindamycin. Consider adding steroids if severe inflammation (vitritis, macular or optic nerve involvement)

# Diabetes Mellitus

- most common cause of blindness in young people in North America
- loss of vision due to:
  - progressive microangiopathy leading to macular edema
  - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
  - rubeosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

## DIABETIC RETINOPATHY

### Background
- altered vascular permeability (loss of pericytes and thickening of basement membrane causing breakdown of blood-retinal barrier)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

### Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - hard exudates (lipid deposits)
  - dot and blot hemorrhages
  - microaneurysms
  - retinal edema
- advanced non-proliferative (or pre-proliferative)
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, leaky collateral vessels within the retina
    - nerve fibre layer (NFL) infarcts (i.e. cotton-wool spots)
- proliferative
  - 5% of patients with DM will reach this stage
  - neovascularization of iris, disc, retina
    - neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
    - vitreous hemorrhage, bleeding from fragile new vessels, fibrous tissue can contract causing tractional RD
  - may remain asymptomatic in early stage
  - high risk of severe vision loss secondary to vitreous hemorrhage, RD

### Screening Guidelines for Diabetic Retinopathy
- type 1 DM
  - screen for retinopathy beginning annually 5 yr after disease onset
  - annual screening indicated for all patients over 12 yr and/or entering puberty
- type 2 DM
  - initial examination at time of diagnosis, then annually
- pregnancy
  - ocular exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
  - patients with gestational diabetes are not at risk of having DR

### Treatment
- 1° prevention: tight control of blood glucose, blood pressure, serum lipid levels, kidney function, and macrovascular complications (Diabetic Control and Complications Trial (DCCT))
- 2° prevention: laser photocoagulation
- 3° prevention:
  - pan-retinal laser photocoagulation (PRP) for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
  - intravitreal injection of corticosteroid or anti-VEGF for fovea-involved diabetic macular edema
  - macular photocoagulation laser for clinically significant macular edema (when not involving centre of macula)
  - vitrectomy for non-clearing vitreous hemorrhage and tractional RD in PDR
    - vitrectomy before vitreous hemorrhage does not improve the visual prognosis

### Lens Changes
- earlier onset of senile nuclear sclerotic and cortical cataracts
- may get hyperglycemic cataract due to sorbitol accumulation (rare)
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters

Macular edema is the most common cause of visual loss in patients with background DR

**Anti-vascular endothelial growth factor for diabetic macular oedema: A network meta-analysis**
Cochrane Database Syst Rev. 2018; 10: CD007419
**Purpose**: To compare the effectiveness and safety of the different anti-VEGF drugs using network meta-analysis methods.
**Results**: Included 24 studies with 6007 patients with DMO and moderate vision loss. Aflibercept, bevacizumab, and ranibizumab were all more effective than laser therapy for improving vision by 3 or more lines after one year. Aflibercept may confer some advantage over ranibizumab and bevacizumab. There were no differences in adverse events.
**Conclusions**: Anti-VEGF drugs are effective at improving vision in people with DMO with three to four in every 10 people likely to experience an improvement of 3 or more lines VA at one year. More evidence on the long-term (greater than two years) comparative effects of these anti-VEGF agents is needed.

Clinically significant macular edema is defined as thickening of the retina at or within 500 µm of the centre of the macula

**Presence of DR in**
**Type 1 DM**
- 25% after 5 yr
- 60% after 10 yr
- >80% after 15 yr

**Type 2 DM**
- 20% at time of diagnosis
- 60% after 20 yr

### Extraocular Muscle Palsy
- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

### Optic Neuropathy
- visual acuity loss due to infarction of optic disc/nerve

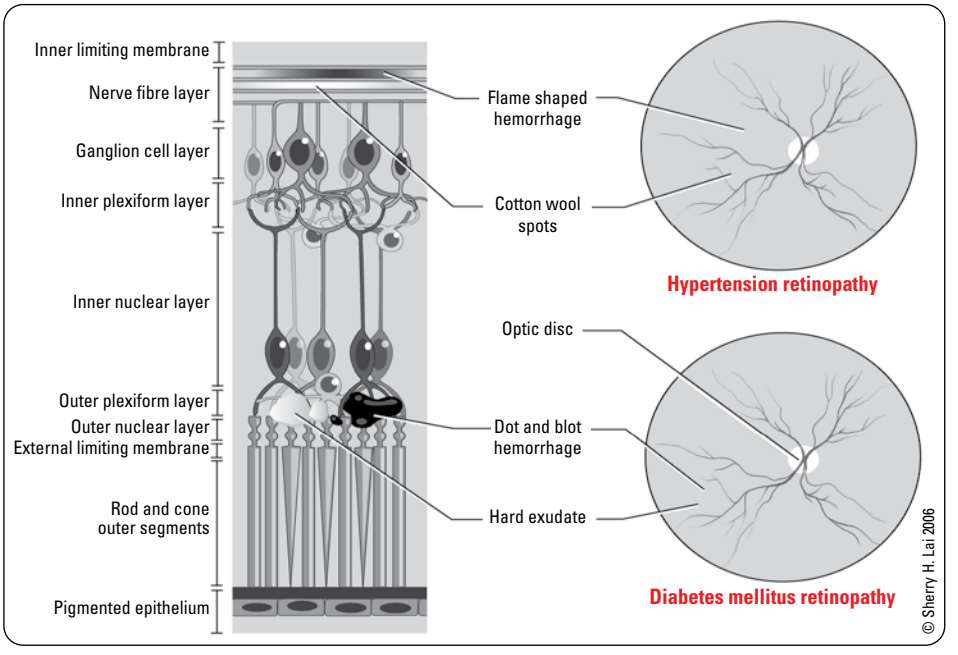

**Figure 24. DM vs. HTN retinopathy**

# Hypertension

- retinopathy is the most common ocular manifestation
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema
- chronic HTN retinopathy: arteriovenous (AV) nicking, flame/blot retinal hemorrhages, cotton wool spots
- increases risk for many other ocular diseases (DR, BRVO, CRAO/BRAO)

**Table 10. Modified Scheie Classification**

| | |
|---|---|
| **Grade 0** | No changes |
| **Grade 1** | Mild arterial narrowing |
| **Grade 2** | Obvious arterial narrowing with focal irregularities |
| **Grade 3** | Grade 2 + retinal hemorrhages and/or exudate |
| **Grade 4** | Grade 3 + swollen optic nerve (malignant HTN) |

# Multiple Sclerosis

- see Neurology, N52

### Clinical Features
- blurred vision and decreased colour vision secondary to optic neuritis
- central scotoma due to damage to papillomacular bundle of retinal nerve fibres
- diplopia secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

### Treatment
- IV steroids with taper to oral form for optic neuritis
  - DO NOT treat with oral steroids in isolation due to increased risk of developing MS

**Aflibercept, Bevacizumab, or Ranibizumab for Diabetic Macular Edema: 2 Year Result from a Comparative Effectiveness Randomized Clinical Trial**
Ophthalmology 2016;123:1351-1359
All 3 anti-VEGF groups showed improvement of VA and deceased number of injections in year 2. Among eyes with worse baseline VA, aflibercept had superior 2 yr VA compared with bevacizumab, but superiority over ranibizumab in year 1 was no longer identified.

**Effects of Medical Therapies on Retinopathy Progression in Type 2 DM**
NEJM 2010;363:233-244
**Purpose**: To determine whether intensive glycemic control, combination therapy for dyslipidemia, and intensive blood pressure control may limit the progression of DR in persons with type 2 DM.
**Methods**: RCT with 10,251 participants with type 2 DM at high risk of cardiovascular disease. Intensive or standard treatment for glycemia (glycated hemoglobin level <6.0% or 7.0-7.9%), dyslipidemia (160 mg daily fenofibrate plus simvastatin or placebo plus simvastatin), or systolic blood-pressure control (target <120 or <140 mmHg).
**Results**: Rates of progression of DR at 4 yr were 7.3% with intensive glycemia treatment vs. 10.4% with standard therapy (OR 0.67; 95% CI 0.51-0.87); 6.5% with fenofibrate for intensive dyslipidemia therapy vs. 10.2% with placebo (OR 0.60; 95% CI 0.42-0.87) and 10.4% with intensive blood pressure therapy vs. 8.8% with standard therapy (OR 1.23; 95% CI 0.84-1.79).
**Conclusions**: Intensive glycemic control and intensive combination treatment of dyslipidemia, but not intensive blood pressure control, reduced the rate of DR.

**Corticosteroids for Treating Optic Neuritis**
Cochrane Database Syst Rev 2015;8:CD001430
**Summary**: no conclusive evidence of benefit in terms of recovery to normal visual acuity, visual field, or contrast sensitivity six mo after initiation of IV or oral corticosteroids.
**Results**: after review of 6 RCTs evaluating systemic corticosteroids for treatment of acute optic neuritis, all meta-analyses show similar outcomes for placebo vs. corticosteroid group for visual acuity, contrast sensitivity, and visual field.

# TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

# Graves' Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur secondary to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

The most common cause of unilateral or bilateral proptosis in adults is Graves' disease

### Clinical
- initial inflammatory phase is followed by a quiescent cicatricial phase

### Treatment
- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, proptosis, and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

**Progression of Signs and Symptoms of Graves' Ophthalmopathy**

**NO SPECS**
**N**o signs/symptoms
**O**nly signs (lid retraction, lid lag)
**S**oft tissue swelling (periorbital edema)
**P**roptosis (exophthalmos)
**E**xtraocular muscle weakness (causing diplopia)
**C**orneal exposure
**S**ight loss

# Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren's syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)

# Giant Cell Arteritis/Temporal Arteritis

- see Rheumatology, RH21

### Clinical Features
- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and PMHx of polymyalgia rheumatica
- ischemic optic atrophy
- 50% lose vision in contralateral eye if untreated

**ESR in Temporal Arteritis**
Males >age/2
Females >(age + 10)/2

### Diagnosis
- temporal artery biopsy + increased ESR and CRP (ESR can be normal, but likely 80-100 in first hour)
- if biopsy is negative, biopsy contralateral side

**Does this Patient have Temporal Arteritis?**
JAMA 2002;287:92-101
**Rule in**: jaw claudication and diplopia on history, temporal artery beading, prominence of the artery and tenderness over the artery on exam.
**Rule out**: no temporal artery abnormalities on exam, normal ESR.

### Treatment
- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start STAT treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation

# Sarcoidosis

### Definition
- granulomatous uveitis with large "mutton fat" keratitic precipitates and posterior synechiae
- complications include glaucoma, cataracts, retinal hemorrhages, peripheral retina neovascularization, and dry eye
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

### Treatment
- topical/systemic steroids and mydriatics

# Pediatric Ophthalmology

## Strabismus

- ocular misalignment in one or both eyes, can be found in up to 3% of children
- **classification**
  - manifest (constant) vs. latent (hidden) alignment
  - comitant (deviation equal in all positions of gaze, also known as non-paralytic or concomitant) vs. incomitant (deviation worse in certain positions, also known as paralytic or restrictive)
  - described in direction of deviation relative to the fixating eye
- distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism)
- complications: amblyopia, cosmesis

Strabismus in children under 4 mo of age sometimes resolves, particularly if the deviation is intermittent, variable, or measures <40 prism diopters

All children with strabismus and/or possible reduced vision require prompt referral to an ophthalmologist

### HETEROTROPIA

- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

### HETEROPHORIA

- latent deviation
- deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

### Types

- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = "crossed-eyes"; exotropia = "wall-eyed"

### Tests

- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle κ)
  - positive in -tropias; negative in -phorias
- cover-uncover test allows to differentiate between -tropias and -phorias
  - any movement of the non-occluded eye in a single cover test indicates a -tropia, as that eye picks up fixation in the absence of visual input to the dominant eye
  - any movement of the occluded eye in a cover-uncover test indicates a -phoria
- alternate cover test
  - alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - maintain cover over one eye for 2-3 s before rapidly shifting to other eye
  - deviation can be quantified using a prism over one eye (alternate prism cover test)

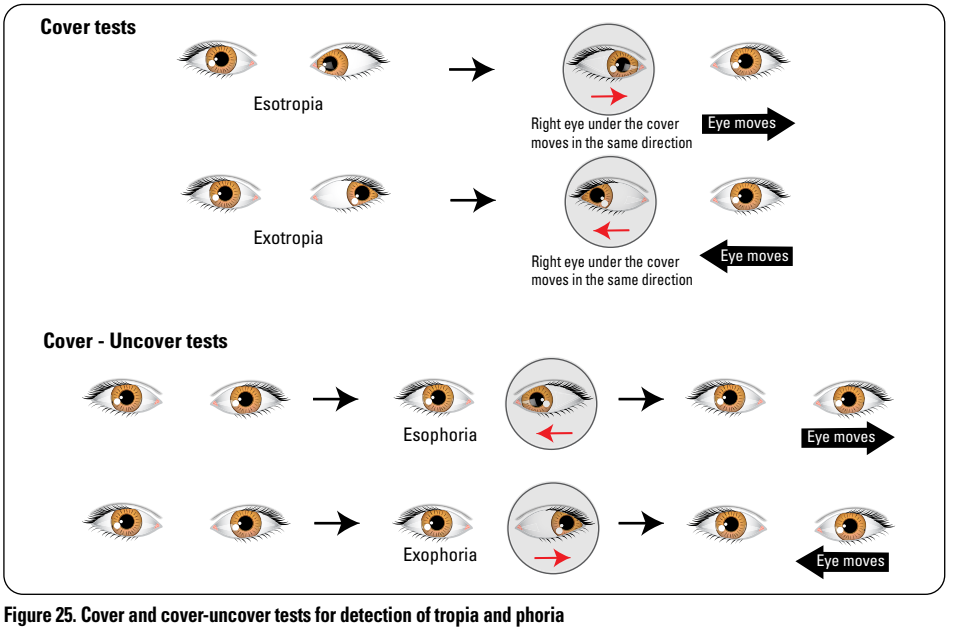

Figure 25. Cover and cover-uncover tests for detection of tropia and phoria

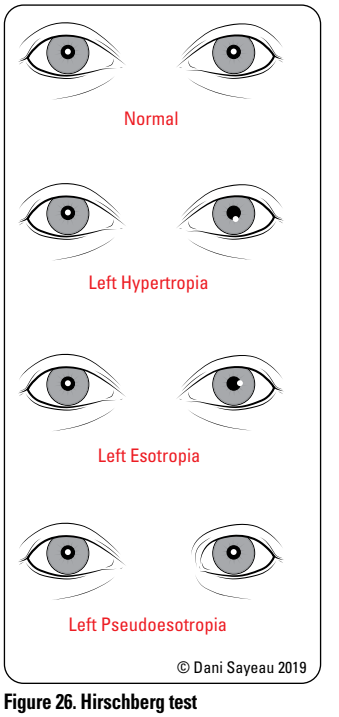

Figure 26. Hirschberg test

**Table 11. Paralytic vs. Non-Paralytic Strabismus**

| Clinical Characteristics | Paralytic Strabismus | Non-paralytic Strabismus |
|---|---|---|
| **Definition** | Incomitant strabismus | Concomitant strabismus |
| **Onset** | Often sudden but may be gradual or congenital | Usually gradual or shortly after birth; rarely sudden |
| **Age of Onset** | Any age; most often acquired | Usually during infancy |
| **Etiology** | Reduction or restriction in range of eye movements due to:<br>Neural (CN III, IV, VI): ischemia (e.g. DM), MS, aneurysm, brain tumour, trauma<br>Muscular: myasthenia gravis (neuromuscular junction pathology), Graves' disease<br>Structural: restriction or entrapment of extraocular muscles due to orbital inflammation, tumour, fracture of the orbital wall | Develops early in childhood<br>No restriction in range of eye movements<br>Monocular, alternating, or intermittent |
| **Diplopia** | Common | Uncommon; image from the misaligned eye is suppressed |
| **Visual Acuity in Other Eye** | Usually unaffected in the other eye, unless CN II is involved | Deviated eye may become amblyopic if not treated when the child is young<br>Amblyopia treatment rarely successful after age 8-10 yr<br>Amblyopia usually does not develop if child has alternating strabismus or intermittency, which allows neural pathways for both eyes to develop |
| **Possibility of Amblyopia** | Uncommon | Common |
| **Neurologic Findings or Systemic Disease** | May be present | Usually absent |

### Accommodative Esotropia
- normal response to approaching object is the triad of the near reflex: convergence, accommodation, and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

### Non-Accommodative Esotropia
- accounts for 50% of childhood strabismus
- most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

### Exotropia
- accounts for 11-18% of childhood strabismus
- congenital: onset before 6 mo, may be associated with other conditions (e.g. neurologic, craniofacial disorders)
- acquired
  - intermittent exotropia: typically apparent when patient is tired of looking in the distance
  - sensory exotropia: eye with poorer vision drifts outward (age ≥2)
  - consecutive exotropia: develops after strabismus surgery

## Amblyopia

### Definition
- most common cause of vision loss in children; a neurodevelopmental visual disorder with unilateral or bilateral (less common) reduction of BCVA that cannot be attributed only to the effect of an ocular structural abnormality
- cannot be remedied immediately by prescription eyewear alone
- errors, anisometropia (asymmetric refractive errors), and concomitant structural ocular problems

### Etiology
- progressive suppression of visual input from eye receiving suboptimal image (blurry, deviated)
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia)
- other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors, usually in the more hyperopic eye), and deprivation due to structural ocular problems (ptosis, cataract, corneal opacity/scarring, retinoblastoma)

### Diagnosis
- "Holler Test": young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately

### Management
- strabismus
  - correct with glasses for accommodative esotropia
  - occlusion therapy (see below)
  - surgery: recession (weakening) by moving muscle insertion further back on the globe or resection (strengthening) by shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until ~8 yr of age
  - no proven value for vision training in the treatment of strabismus or amblyopia
- anisometropia
  - the more emmetropic (normally-refracting) eye receives a clear image, while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if visual acuity difference persists after using glasses for 4-8 wk
- deprivation: treat underlying cause
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
  - prognosis: 90% will have good vision restored and maintained if treated before age 4

### Occlusion Therapy
- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision with follow-up to prevent occlusion ambylopia
- cycloplegic drops (e.g. atropine) to impair accommodation and blur vision of the good eye

### Risks
- permanent loss of vision in the affected eye
- possibility of injury to "remaining" good eye (e.g. occlusion amblyopia)
- safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is <20/50
- loss of stereopsis

## Leukocoria

### Definition
- white reflex (red reflex is absent)
- the presence of leukocoria warrants urgent referral to an ophthalmologist

### Differential Diagnosis
- retinoblastoma
- cataract
- Coats disease (exudative retinal telangiectasis)
- persistent hyperplastic primary vitreous or persistent fetal vasculature
- retinal coloboma (chorioretinal)
- RD
- congenital infections, e.g. toxoplasmosis and toxocariasis
- ROP

## Retinoblastoma

### Definition
- intraocular malignancy that rapidly develops from immature cells of the retina

### Epidemiology
- most common primary intraocular malignancy in children
- incidence: 1/15000
- unilateral (2/3) or bilateral (1/3)
- malignant – direct or hematogenous spread

### Etiology
- sporadic or genetic transmission; screening of siblings/offspring essential
- inherited forms likely to be bilateral
- often caused by mutations in RB1 on ch13q14, the first tumour suppressor gene discovered, and less commonly by amplifications of MYCN, an oncogene

### Diagnosis
- often presents with leukocoria and/or strabismus
- others signs: red eye, eye enlargement if advanced disease
- fundus examination (nodular, white/cream-coloured masses with intralesional blood vessels)
- CT, U/S (A & B-scan), or MRI may demonstrate RD and/or calcified mass (present in most cases)

### Treatment
- local (laser, cryotherapy), systemic (radiotherapy, chemotherapy), and/or enucleation + genetic counselling

**Retinal Zones**
- Zone I: circle with radius twice the distance from the disc to the macula (most difficult to treat)
- Zone II: annulus from zone I to nasal extent of retina (nasal ora serrata)
- Zone III: remaining retina

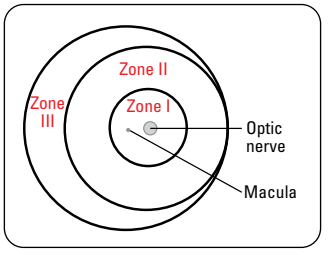

**Figure 27. Zones of the retina in ROP**

# Retinopathy of Prematurity

### Definition
- vasoproliferative retinopathy that is a major cause of blindness in the developed world

### Risk Factors
- non-black race (black infants have lower risk of developing ROP)
- earlier gestational age, birth weight <1500 g, low caloric intake, postnatal hyperglycemia,
- high oxygen exposure after birth (iatrogenic), i.e. assisted ventilation >1 wk

### Classification (ROP Staging)
- stage 1: flat white demarcation line at the junction between the vascular and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula "on", 4B: macula "off")
- stage 5: total RD
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with circumferential extent of ROP involvement in 5 continuous or 8 cumulative clock hours (1-12)

### Treatment
- laser ablation is currently the treatment standard for stages 1-3; intravitreal bevacizumab showed significant benefits in zone I compared to laser ablation therapy in infants with stage 3+ ROP
- stage 4-5 is treated with vitrectomy/scleral buckle (goal is to release vitreous tractional forces on the retina)

### Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

**Anti-VEGF Drugs for Treatment of Retinopathy of Prematurity (ROP)**
Cochrane Database Syst Rev 2018;1:CD009734
**Summary/Conclusions**: Review of 6 RCTs/Quasi-RCTs comparing anti-VEGF agents vs. conventional therapy for ROP (n=383).
- Insufficient data precludes strong conclusions for routine use of intravitreal anti-VEGF agents for treatment of ROP
- Intravitreal bevacizumab/ranibizumab as monotherapy reduces risk of refractory errors during childhood.
- Intravitreal pegaptanib + laser therapy reduces the risk of retinal detachment for type 1 ROP
- Effect on other critical outcomes and long-term systemic adverse effects are unknown

# Nasolacrimal System Defects

### Definition
- congenital obstruction of the nasolacrimal duct (failure of canalization) at valve of Hasner, ~1-2 mo of age

### Signs and Symptoms
- epiphora (overflow of tears), periocular crusting, mucopurulent discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac

### Treatment
- circular massage over lacrimal sac at medial canthus
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing

# Ophthalmia Neonatorum

### Definition
- purulent conjunctivitis with profuse exudate in the first few days of life; can cause blindness

### Etiology
- chemical/toxic: silver nitrate, erythromycin (secondary to prophylaxis, self-limiting)
- infectious: bacterial (e.g. *N. gonorrhoeae* – most common, *C. trachomatis*), herpes simplex virus

### Treatment
- systemic antibiotics and saline irrigation with possible hospitalization if infectious etiology

Gonococcal infection is the most serious threat to sight as it can rapidly penetrate corneal epithelium, causing corneal ulceration

# Congenital Glaucoma

### Definition
- elevated IOP within the first year of life

### Etiology
- not entirely known – may be due to inadequate development of anterior chamber
- sporadic and hereditary (autosomal recessive); males more often affected
- secondary congenital glaucoma can be associated with ocular and systemic disorders
  - ocular: aniridia, microcornea, megalocornea, cornea plana, iridoschisis, microphthalmos, persistent hyperplastic primary vitreous, posterior polymorphous dystrophy
  - systemic: Prader-Willi, trisomies, fetal alcohol syndrome, mucopolysaccharidoses, and many others

Epiphora in children – rule out congenital glaucoma

### Clinical Features
- photophobia, epiphora, and blepharospasm
- cloudy cornea due to edema; Haab's striae due to breaks in Descemet's membrane
- increased IOP, rapidly-progressive myopia
- buphthalmos (large cornea, "ox eye") and enlarged C:D

### Treatment
- immediate filtration surgery after birth

# Ocular Trauma

## Blunt Trauma

- caused by blunt object such as fist
- HPI: injury, ocular history, drug allergy, tetanus status
- PEx: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
  - if VA normal or slightly reduced: globe less likely to be perforated
  - if VA reduced: possible globe perforation, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema
- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion (detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope)
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- vitreous: hemorrhage
- retina: tear, detachment

Always test VA first – medicolegal protection

**Refer if You Observe Any of These Signs**
- Decreased VA
- Shallow anterior chamber
- Hyphema
- Abnormal pupil
- Ocular misalignment
- Retinal damage

## Penetrating Trauma

- includes: ruptured globe ± lid laceration, prolapsed iris, intraocular foreign body
- rule out intraocular foreign body with CT orbit, especially if history of "metal striking metal"
- **OCULAR EMERGENCY**: initial management - REFER IMMEDIATELY
  - ABCs
  - avoid pressing on eye globe
  - avoid checking IOP
  - check vision, diplopia
  - apply rigid eye shield to minimize further trauma
  - keep head elevated 30-45° to keep IOP down
  - keep NPO
  - tetanus status
  - give IV antibiotics
    - selecting appropriate agents depends on the mechanism of injury; Gram-positive bacteria are more commonly involved than Gram-negative; retained intraocular foreign objects increase the risk of infections with *Bacillus* species, whereas exposure to vegetable matter increase the risk of a fungal etiology

**Management of Suspected Globe Rupture**
**CAN'T** forget
**CT** orbits
**A**ncef (cefazolin) ± Aminoglycoside IV
**N**PO
**T**etanus status

**Post-Traumatic Infectious Endophthalmitis**
Surv Ophthalmol 2011;56:214-251
- Delayed primary repair (>24 h after open globe injury) increases risk for post-traumatic endophthalmitis in the absence of an intraocular foreign body (IOFB).
- If IOFB present, early vitrectomy and IOFB removal must be performed within 24 h of injury.
- Extreme pain with hypopyon and vitritis indicate endophthalmitis until proven otherwise, and samples must be obtained.
- Treat with empirical intravitreal and intravenous antibiotic guided by nature of trauma, and adjust based on culture.

## Hyphema

### Definition
- blood in anterior chamber, often due to damage to root of the iris
- may occur with blunt trauma

### Treatment
- refer to ophthalmology
- shield and bedrest for 5 d or as determined by ophthalmologist
- sleep with head upright
- may need surgical drainage if hyphema persists or if re-bleed

### Complications
- risk of re-bleed highest on day 2-5, and may result in secondary glaucoma, corneal staining, and iris necrosis
- never prescribe Aspirin® (increases risk of re-bleed)

**Shaken Baby Syndrome**
Syndrome of findings characterized by absence of external signs of abuse with respiratory arrest, seizures, or coma. Ocular exam findings are important diagnostically for Shaken Baby Syndrome. These findings include extensive retinal and vitreous hemorrhages that occur during the shaking process and are extremely rare in accidental trauma. A detailed fundoscopic exam or an ophthalmology referral should be conducted for all infants in whom abuse is suspected

**Classic Signs of Blow-Out**
- Enophthalmos
- Decreased upgaze (inferior rectus trapped)
- Cheek anesthetized (infraorbital nerve trapped)

# Blow-Out Fracture

• see Plastic Surgery, PL33

### Definition
- blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- orbital rim remains intact
- inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- infraorbital nerve courses along the floor of the orbit and may be damaged

### Clinical Features
- pain and nausea at time of injury
- diplopia, restriction of EOM
- infraorbital and upper lip paresthesia or anesthesia (CN V2)
- enophthalmos (sunken eye), periorbital ecchymoses

### Investigations
- plain films: Waters' view (occipitomental view)
- CT: anteroposterior and coronal view of orbits

### Treatment
- refrain from coughing, blowing nose
- systemic antibiotics may be indicated
- surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- may delay surgery if the diplopia improves

# Chemical Burns

- alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- poor prognosis if cornea opaque, likely irreversible stromal damage
- even with a clear cornea initially, alkali burns can progress for weeks – thus, very guarded prognosis

### Treatment
- immediately irrigate site of accident with water or balanced saline solution (BSS)
  - irrigate with eyelids retracted in emergency department with IV drip to physiologic pH (test with litmus paper)
  - swab upper and lower fornice to remove possible particulate matter
- do not attempt to neutralize an acid with a base, or vice versa
- topical antibiotics and patching
- cycloplegic drops to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
- topical antibiotics and patching
- topical steroids (prescribed by ophthalmologist) to decrease inflammation, use for <2 wk in the case of a persistent epithelial defect

# Ocular Drug Toxicity

**Table 12. Drugs with Ocular Toxicity**

| | |
|---|---|
| **Amiodarone** | Corneal microdeposits and superficial keratopathy (vortex keratopathy)<br>Rare: ischemic optic neuropathy |
| **Atropine, benztropine** | Pupillary dilation (risk of angle-closure glaucoma) |
| **Bisphosphonates (Fosamax®, Actonel®)** | Inflammatory eye disease (iritis, scleritis, episcleritis) |
| **Chloroquine, hydroxychloroquine** | Bull's eye maculopathy<br>Vortex keratopathy |
| **Chlorpromazine** | Anterior subcapsular cataract |
| **Contraceptive pills** | Decreased tolerance to contact lenses<br>Migraine<br>Optic neuritis<br>Central vein occlusion, benign increase in intracranial pressure |
| **Digitalis** | Yellow vision<br>Blurred vision |
| **Ethambutol** | Optic neuropathy |
| **Haloperidol (Haldol®)** | Oculogyric crises<br>Blurred vision |
| **Indomethacin** | Superficial keratopathy |

**Table 12. Drugs with Ocular Toxicity** (continued)

| | |
|---|---|
| **Interferon** | Retinal hemorrhages and cotton wool spots |
| **Isoniazid** | Optic neuropathy |
| **Nalidixic acid** | Papilledema |
| **Steroids** | Posterior subcapsular cataracts<br>Glaucoma<br>Papilledema (systemic steroids)<br>Increased severity of HSV infections (geographic ulcers)<br>Predisposition to fungal infections |
| **Sulphonamides, NSAIDs** | Stevens-Johnson syndrome |
| **Tamsulosin (Flomax®)** | Intraoperative floppy iris syndrome (can complicate cataract surgery) |
| **Tetracycline** | Papilledema (associated with pseudotumour cerebri) |
| **Thioridazine** | Pigmentary degeneration of retina |
| **Vigabatrin** | Retinal deposition with macular sparing, peripheral visual field loss |
| **Vitamin A toxicity** | Papilledema |
| **Vitamin D toxicity** | Band keratopathy |

# Common Medications

## TOPICAL OCULAR DIAGNOSTIC DRUGS

### Fluorescein Dye
- water-soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope, slit-lamp ± applanation tonometry)
- absorbed in areas of epithelial loss (ulcer, abrasion, laceration)
- stains mucus, contact lenses, foreign bodies

### Rose Bengal Stain
- stains devitalized epithelial cells and mucus to indicate tear film abnormalities (e.g. mucin deficiency)

### Anesthetics
- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore NEVER prescribe

### Mydriatics
- dilate pupils
- two classes
  - cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    - dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    - indications: refraction, ophthalmoscopy, therapy for iritis
  - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    - stimulate pupillary dilator muscles, no effect on accommodation
    - usually used with tropicamide for additive effects
    - side effects: HTN, tachycardia, arrhythmias

**Table 13. Mydriatic Cycloplegic Drugs and Duration of Action**

| Drugs | Duration of Action |
|---|---|
| Tropicamide (Mydriacyl®) 0.5%, 1% | 4-5 h |
| Cyclopentolate HCl 0.5%, 1% | 3-6 h |
| Homatropine HBr 1%, 2% | 3-7 d |
| Atropine sulfate 0.5%, 1% | 1-2 wk |
| Scopolamine HBr 0.25%, 5% | 1-2 wk |

| | |
|---|---|
| **Green** | Cholinergics |
| **Red** | Anti-cholinergics |
| **White** | Anesthetics, antibiotics, artificial tears, steroids |
| **Yellow** | β-blockers |
| **Blue** | β-blocker combinations |
| **Purple** | α-agonists |
| **Teal** | Prostaglandins |
| **Orange** | Carbonic anhydrase inhibitors |
| **Tan** | Fluoroquinolones |
| **Grey** | NSAIDs |
| **Pink** | Anti-inflammatories, steroids |

## GLAUCOMA MEDICATIONS

**Table 14. Glaucoma Medications**

| Drug Category | Dose | Effect | Comment/Side Effects |
|---|---|---|---|
| **α-Agonist**<br>**Non-selective**<br>• epinephrine HCl 1% (Epifrin®)<br>• dipivalyl epinephrine 0.1% (Propine®)<br>**α2-selective**<br>• brimonidine 0.2% (Alphagan®)<br>• apraclonidine 0.5% (Iopidine®) | 1 gtt OS/OD bid/tid | 1. Non-selective: reduced aqueous production + increased TM outflow<br>2. Selective: reduced aqueous production + increased uveoscleral outflow | 1. Non-selective: mydriasis, macular edema, tachycardia<br>2. Selective: contact allergy, hypotension in children |
| **β-Blocker**<br>**Non-selective**<br>• timolol (Timoptic®)<br>• levobunolol (Betagan®)<br>**β 1-selective**<br>• betaxolol (Betoptic®) | 1 gtt OS/OD qd/bid | Reduced aqueous production | **Bronchospasm (caution in asthma/COPD)**<br>Increased CHF<br>Bradycardia, hypotension, depression, heart block, impotence |
| **Carbonic Anhydrase Inhibitor**<br>• dorzolamide (Trusopt®)<br>• brinzolamide (Azopt®)<br>• oral: acetazolamide (Diamox®), methazolamide (Neptazane®) | 1 gtt OS/OD tid<br>Diamox®: 500 mg PO bid | Reduced aqueous production | **Must ask about sulfa allergy**<br>Generally local side effects with topical preparations<br>Oral: diuresis, fatigue, paresthesia, GI upset |
| **Parasympathomimetic**<br>(cholinergic stimulating)<br>• pilocarpine (Pilopine®)<br>• carbachol (Isopto Carbachol®) | 1-2 gtts OS/OD tid/qid | Increased TM outflow | Miosis<br>Reduced night vision<br>Increased GI motility, brow ache, headache<br>Reduced heart rate |
| **Prostaglandin Analogues**<br>• latanoprost (Xalatan®)<br>• travaprost (Travatan®)<br>• bimatoprost (Lumigan®) | 1 gtt OS/OD qhs | Increased uveoscleral outflow (uveoscleral responsible for 20% of drainage) | Iris colour change<br>Periorbital skin pigmentation<br>Lash growth<br>Conjunctival hyperemia |

Cosopt® = timolol + dorzolamide; Xalacom® = timolol + lantanoprost; Combigan® = timolol + brimonidine; DuoTrav® = tinolol + travaprost; gtt = drop, gtts = drops

## WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

### VEGF Inhibitors (Anti-VEGF)

- anti-VEGF agents prevent ocular angiogenesis and further development of choroidal neovascularization
- administered via intravitreal injections
- alflibercept (Eylea®) is a VEGF "trap" agent that binds VEGF-A, B, and placental growth factor
- ranibizumab (Lucentis®) is a monoclonal Fab fragment and non-selective anti-VEGF agent
- bevacizumab (Avastin®) is recombinant humanized monoclonal antibody and non-selective anti-VEGF agent
  - FDA approved only for metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its widespread ophthalmologic use is off-label

**Intravitreal Bevacizumab Versus Ranibizumab for Treatment of Neovascular Age-Related Macular Degeneration: Findings from a Cochrane Systematic Review**
Ophthalmology 2016; 123(1):70-77
**Summary:** In 6 RCTs with 2809 participants, there were no important differences in effectiveness or safety between bevacizumab and ranibizumab, despite a significant cost difference.

## TOPICAL OCULAR THERAPEUTIC DRUGS

### NSAIDs

- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

### Anti-Histamines

- used to relieve red and itchy eyes, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes
- Olopatadine (Patanol®, Patady®)

### Decongestants

- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine (Isopto Frin®)
- rebound vasodilation with overuse; rarely can precipitate angle-closure glaucoma

### Antibiotics

- indications: bacterial and hyperpurulent conjunctivitis, corneal abrasions and ulcers, endophthalmitis, keratitis, blepharitis, globe rupture, cellulitis, lacrimal sac, and gland infections
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin®), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan®], ofloxacin [Ocuflox®], moxifloxacin [Vigamox®], gatifloxacin [Zymar®])

**Antiplatelet and Anticoagulant Drugs Do Not Affect Visual Outcome in Neovascular Age-Related Macular Degeneration in the BRAMD Trial**
Am J Ophthalmol 2018;187:130-137
**Summary:** In 330 NVAMD patients receiving either bevacizumab or ranibizumab treatment, use of anti-coagulant and anti-platelet agents was not associated with visual decline or occurrence of ocular hemorrhages.

### Corticosteroids

- e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone (Predsol® 0.5%, Pred Forte® 1%), rimexolone (Vexol®), loteprednol etabonate 0.5% (Lotamax®), difluprednate (Durezol®)
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
  - potentiates HSV keratitis and fungal keratitis as well as masking symptoms
  - increased IOP, more rapidly in steroid responders (within weeks)
  - posterior subcapsular cataract (within months)

# Fractures – General Principles

## Fracture Description

### 1. Name of Injured Bone

### 2. Integrity of Skin/Soft Tissue
- closed: skin/soft tissue over and near fracture is intact
- open: skin/soft tissue over and near fracture is lacerated or abraded, such that fracture site communicates with outside environment, or contaminated (i.e. bowel)
- signs: continuous bleeding from puncture site, or fat droplets in blood are suggestive of an open fracture

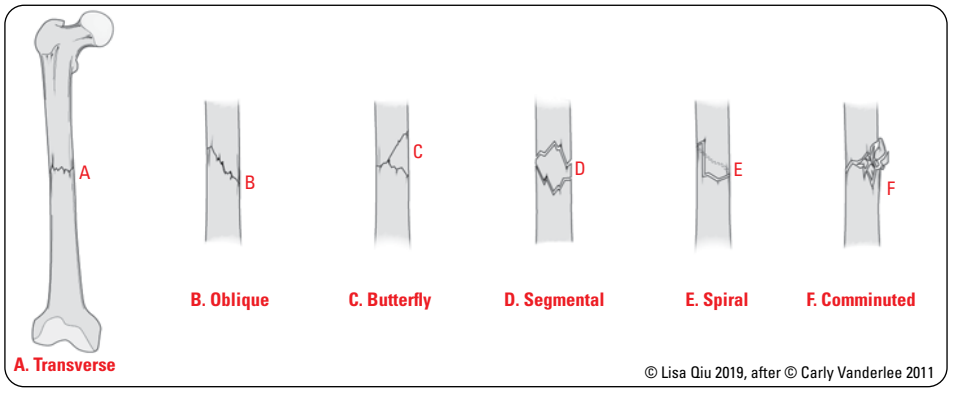
### 3. Location
- epiphyseal: end of bone, forming part of the adjacent joint
- metaphyseal: the flared portion of the bone at the ends of the shaft
- diaphyseal: the shaft of a long bone (proximal, middle, distal)
- physis: growth plate

### 4. Orientation/Fracture Pattern (Figure 4)
- transverse: fracture line perpendicular (<30° of angulation) to long axis of bone; result of direct high energy force
- oblique: angular fracture line (30°- 60° of angulation); result of angulation and compressive force, high energy
- butterfly: triangular or wedge-shaped fragment resembling a butterfly; commonly between the two main fracture fragments in comminuted long bone fractures
- segmental: a separate segment of bone bordered by fracture lines; often the result of high-energy force
- spiral: complex, multi-planar fracture line; result of rotational force, low energy
- comminuted/multi-fragmentary: >2 fracture fragments
- intra-articular: fracture line crosses articular cartilage and enters joint
- compression: impaction of bone; typical sites are vertebrae or proximal tibia
- torus: compression of bony cortex on one side while the other remains intact, often seen in children (Figure 50)
- greenstick: compression of one side with fracture of the opposite cortex, often seen in children (Figure 50)
- pathologic: fracture through abnormal bone weakened by disease (e.g. tumour)

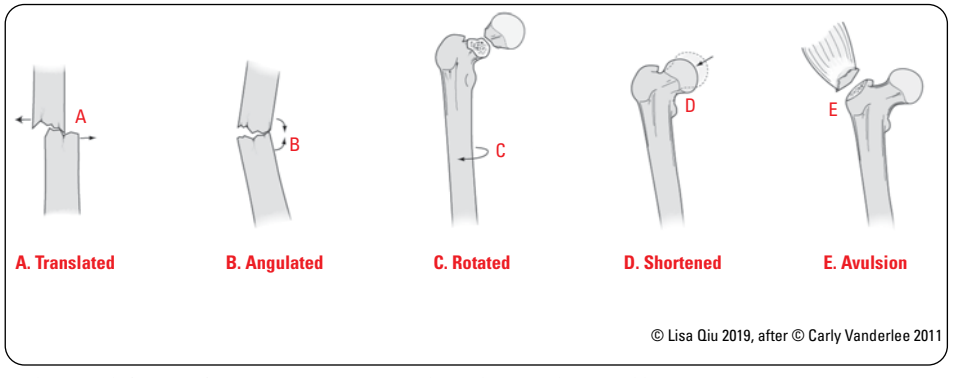
**Displacement**
Refers to position of the distal fragment relative to the proximal fragment

**Varus/Valgus Angulation**
Varus = Apex toward midline
Valgus = Apex away from midline

**Quick Motor Nerve Exam**
"Thumbs Up": PIN (Radial Nerve)
"OK Sign": AIN (Median Nerve)
"Spread Fingers": Ulnar Nerve



**X-Ray Rule of 2s**
2 sides = bilateral
2 views = AP + lateral
2 joints = joint above + below
2 times = before + after reduction



**Sample Fracture Description**
Closed (overlying skin integrity) spiral fracture (fracture pattern) of the distal third (location) of the left tibia (injured bone), with mild varus angulation, lateral translation and angulation (alignment of fracture fragments). The fracture does not extend to the joint surface

### 5. Alignment of Fracture Fragments (Figure 5)

- non-displaced: fracture fragments are in anatomic alignment
- displaced: fracture fragments are not in anatomic alignment
- distracted: fracture fragments are separated by a gap (opposite of impacted)
- translated: percentage of overlapping bone at fracture site
- angulated: direction of fracture apex (e.g. varus/valgus)

- rotated: fracture fragment rotated about long axis of bone

- shortened: fracture fragments are compressed, resulting in shortened bone
- avulsion: tendon or ligament tears/pulls off bone fragment

**Figure 4. Orientation/fracture pattern**
**Figure 5. Alignment of fracture fragments**

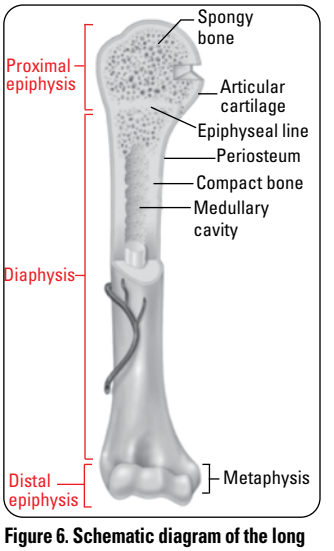


**Figure 6. Schematic diagram of the long bone**

# Approach to Fractures

### 1. Clinical Assessment

- ABCs, primary survey, and secondary survey (ATLS protocol)
  - assess for life threatening injury and other fractures
  - assess for open fracture
- **AMPLE- F** history (minimum): **A**llergies, **M**edications, **P**ast medical history, **L**ast meal, **E**vents (mechanism of injury), **F**unction pre-injury
  - previous significant injury or surgery to affected area
  - consider pathologic fracture with history of only minor trauma
- physical exam: inspect (deformity, soft tissue integrity); palpate (maximal tenderness, NVS- document best possible neurovascular exam, avoid ROM/moving injured area to prevent exacerbation)

### 2. Analgesia

- Oral, IV or local (e.g. hematoma block)

### 3. Imaging (see *Orthopedic X-Ray Imaging*, OR8)

### 4. Reduction: Closed vs. Open

- closed reduction (with IV sedation and muscle relaxation if necessary)
  - apply traction in the long axis of the limb
  - reverse the mechanism that produced the fracture
- open reduction
  - "NO CAST" (see sidebar)
  - other indications include
    - failed closed reduction
    - unable to cast or apply traction due to site
    - pathologic fractures
    - potential for improved function and/or outcomes with ORIF
- ALWAYS re-check and document NVS after reduction and obtain post-reduction x-ray

**Reasons for Closed Reduction and Splinting**

- Pain control
- Reduces further damage to vessels, nerves, and skin and may improve neurovascular status
- Reduces point loading on articular surfaces
- Decreases risk of inadvertently converting closed to open fracture
- Facilitates patient transport

**Indications for Open Reduction**

**NO CAST**
**N**on-union
**O**pen fracture
Neurovascular **C**ompromise
Displaced intra-**A**rticular fracture
**S**alter-Harris 3,4,5
Poly**T**rauma

**Buck's Skin Traction**
A system of weights, pulleys, and ropes that are attached to the end of a patient's bed exerting a longitudinal force on the distal end of a fracture, improving its length, alignment, and rotation temporarily while awaiting fixation (typically used for lower extremity fractures)

**5. Immobilization**
- external stabilization: splints, casts, traction, external fixator
- internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixation (rods)

**6. Follow-Up**
- evaluate stages of bone healing (see *Fracture Healing*, OR10)

**7. Rehabilitation**
- recommend rehabilitation when appropriate to regain function and avoid joint stiffness

**Normal Healing**

| | |
|---|---|
| Weeks 0-3 | Hematoma, macrophages surround fracture site |
| Weeks 3-6 | Osteoclasts remove sharp edges, callus forms within hematoma |
| Weeks 6-12 | Bone forms within the callus, bridging fragments |
| Months 6-12 | Cortical gap is bridged by bone |
| Years 1-2 | Normal architecture is achieved through remodelling |

**Wolff's Law**
Bone adapts to the amount of force applied by increasing or decreasing its mass to resist the applied stress

# Fracture Healing

**Figure 7. Stages of bone healing**

## Evaluation of Healing: Tests of Union
- clinical: no longer tender to palpation or stressing on physical exam
- x-ray: trabeculae cross fracture site, visible callus bridging site on at least 3 of 4 cortices

**Fracture Blister**
Formation of vesicles or bullae that occur on edematous skin overlying a fractured bone

# General Fracture Complications

**Table 3. General Fracture Complications**

| | Early | Late |
|---|---|---|
| **Local** | Compartment syndrome<br>Neurological injury<br>Vascular injury<br>Infection<br>Implant failure<br>Fracture blisters | Mal-/non-union<br>AVN<br>Osteomyelitis<br>Heterotopic ossification<br>Post-traumatic OA<br>Joint stiffness/adhesive capsulitis<br>CRPS type I/RSD |
| **Systemic** | Sepsis<br>DVT<br>PE<br>ARDS secondary to fat embolism<br>Hemorrhagic shock | |

**Heterotopic Ossification**
The formation of bone in abnormal locations (e.g. in muscle), secondary to pathology

**CRPS/RSD**
An exaggerated response to an insult in the extremities; characterized by symptoms of hyperalgesia and allodynia, with signs of autonomic dysfunction (temperature asymmetry, mottling, hair or nail changes)

**Avascular Necrosis**
Ischemia of bone due to disrupted blood supply; most commonly affecting the femoral head, talus, or proximal scaphoid

# Articular Cartilage

## Properties
- hyaline cartilage
- 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
- avascular (nutrition from synovial fluid), aneural, alymphatic

### ARTICULAR CARTILAGE DEFECTS

## Etiology
- overt trauma, repetitive minor trauma (such as repetitive ankle sprains or patellar maltracking)
- degenerative conditions such as early stage OA or osteochondritis dissecans

**Osteochondritis Dissecans**
Avascular necrosis of subchondral bone most often occurring in children and adolescents and causing pain and potentially hindering joint motion

## Clinical Features
- part of OA presentation: pain with movement, decreased range of motion, joint line pain with possible effusion
- have predisposing factors such as: ligament injury; malalignment of the joint (e.g. varus or valgus); obesity; AVN; and inflammatory arthropathy
- may have symptoms of locking or catching related to the torn/displaced cartilage

## Investigations
- X-ray (to rule out bony defects and check alignment)
- MRI (if X-ray is normal; MRI is not needed to assess cartilage loss associated with osteoarthritis)

**Table 4. Outerbridge Classification of Chondral Defects**

| Grade | Chondral Damage |
|---|---|
| I | Softening and swelling of cartilage |
| II | Fragmentation and fissuring <1/2" in diameter |
| III | Fragmentation and fissuring >1/2" in diameter |
| IV | Erosion of cartilage down to bone |

### Treatment
- individualized
  - patient factors (age, skeletal maturity, activity level, etc.)
  - defect factors (Outerbridge Classification, subchondral bone involvement, etc.)
- non-operative
  - rest, NSAIDs, bracing, physiotherapy
- operative
  - microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

# Orthopedic X-Ray Imaging

### General Principles - "Rule of 2s"
- x-ray 1 joint above and 1 below
- obtain at least 2 orthogonal views ± specialized views
- 2 sides, as needed for comparison

**Table 5. Orthopedic X-Ray Imaging**

| Site | Injury | X-Ray Views |
|---|---|---|
| **Shoulder** | Anterior dislocation<br>Posterior dislocation<br>AC | AP<br>Axillary ± stress view with 10 lb in hand<br>Trans-scapular<br>Zanca view (10-15 cephalic tilt) |

# Orthopedic Emergencies

## Trauma Patient Workup

### Etiology
- high energy trauma e.g. MVC, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

### Clinical Features
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension, hypovolemia
- consider involvement of EtOH or other psychoactive substances

### Investigations
- trauma survey (see Emergency Medicine, ER7)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- CT is also utilized to inspect for musculoskeletal injuries in the trauma setting
- other views of pelvis: AP, inlet, and outlet; Judet views for acetabular fracture (see *Classification of Pelvic Fractures* Table 19, OR28)

### Treatment
- ABCDEs and initiate resuscitation for life-threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

### Complications
- hemorrhage – life-threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis if missed open fracture

## Open Fractures

- fractured bone and hematoma in communication with the external or contaminated environment

### Emergency Measures
- ABCs, primary survey, and resuscitation as needed
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated
- cover wound with sterile dressings
- immediate IV antibiotics
- tetanus toxoid or immunoglobulin as needed (see Plastic Surgery, PL10)
- NPO and prepare for OR (blood work, consent, ECG, CXR)
  - operative irrigation and debridement within 6-8 h to decrease risk of infection
  - ORIF
  - traumatic wound may be left open to drain with vacuum-assisted closure if necessary
  - re-examine with repeat irrigation and debridement in 48 h if necessary

**Table 6. Gustilo Classification of Open Fractures**

| Gustilo Grade | Length of Open Wound | Description | Prophylactic Antibiotic Regimen |
|---|---|---|---|
| I | <1 cm | Minimal contamination and soft tissue injury<br>Simple or minimally comminuted fracture | First generation cephalosporin (cefazolin) 2 g IV q8h for 2 d<br>If allergy use clindamycin 900 mg IV q8h<br>If MRSA positive use vancomycin 15 mg/kg IV q12h |
| II | 1-10 cm | Moderate contamination<br>Moderate soft tissue injury | As per Grade I |
| III* | >10 cm | IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound<br>IIIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound<br>IIIC: Vascular injury/compromise | First generation cephalosporin (cefazolin) for 2 d plus Gram-negative coverage (gentamicin or ceftriaxone) for at least 3 d<br>For soil or fecal contamination, metronidazole is added for anaerobic coverage ± penicillin G<br>If MRSA positive use vancomycin 15 mg/kg IV q12h |

*Any high energy, comminuted fracture, shot gun, farmyard/soil/water contamination, exposure to oral flora, or fracture >8 h old is immediately classified as Grade III

**Orthopedic Emergencies**

**VON CHOP**
**V**ascular compromise
**O**pen fracture
**N**eurological compromise/cauda equina syndrome
**C**ompartment syndrome
**H**ip dislocation
**O**steomyelitis/septic arthritis
Unstable **P**elvic fracture

**Controversies in Initial Management of Open Fractures**
Scand J Surg 2014;103(2):132-7
**Study**: Literature review examining the initial management of open fractures. 40 studies included.
**Findings:**
- A first-generation cephalosporin (or clindamycin) should be administered upon arrival. In general, 24 h of antibiotics after each debridement is sufficient to reduce infection rates.
- Although cultures are taken from delayed (>24 h) or infected injuries, it may not be necessary to routinely take post-debridement cultures in open fractures.
- Open fractures should be debrided as soon as possible, although the "6 h rule" is not generally valid.
- Wounds should be closed within 7 d once soft tissue has stabilized and all non-viable tissue removed.
- Negative pressure wound therapy (NPWT) has been shown to decrease infection rates in open fractures.

33% of patients with open fractures have multiple injuries

**Antibiotics for Preventing Infection in Open Limb Fractures**
Cochrane DB Syst Rev 2004;1:CD003764
**Purpose**: To review the evidence regarding the effectiveness of antibiotics in the initial treatment of open fractures of the limbs.
**Methods**: Randomized or quasi-randomized controlled trials comparing antibiotic treatment with placebo or no treatment in preventing acute wound infection were identified and reviewed. Data were extracted and pooled for analysis.
**Results**: Eight studies (n=1106) were reviewed. The use of antibiotics had a protective effect against early infection compared with no antibiotics or placebo (RRR=0.43, 95% CI 0.29, 0.65; ARR=0.07, 95% CI 0.03–0.10).
**Conclusions**: Antibiotics reduce the incidence of early infections in open fractures of the limbs.

# Cauda Equina Syndrome

- see Neurosurgery, NS27

# Compartment Syndrome

- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment), with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure, leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

## Etiology

- intracompartmental
  - fracture (particularly tibial shaft or paediatric supracondylar and forearm fractures)
  - reperfusion injury, crush injury, or ischemia
- extracompartmental: constrictive dressing (circumferential cast), poor position during surgery, circumferential burn

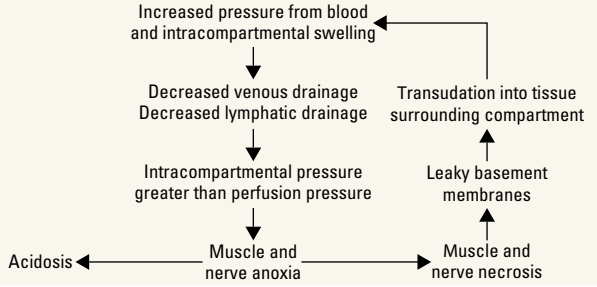

**Figure 8. Pathogenesis of compartment syndrome**

## Clinical Features

- pain out of proportion to injury (typically first symptom and the most significant finding)
- pain with active contraction of compartment
- pain with passive stretch (most sensitive)
- swollen, tense compartment
- suspicious history

- **5 Ps:** late sign – do not wait for these to develop to make the diagnosis!

Most important sign is increased pain with passive stretch. Most important symptom is pain out of proportion to injury

**5 Ps of Compartment Syndrome**
**P**ain: out of proportion for injury and not relieved by analgesics
- Increased pain with passive stretch of compartment muscles

**P**allor: late finding
**P**aresthesia
**P**aralysis: late finding
**P**ulselessness: late finding

## Investigations

- usually not necessary, as compartment syndrome is a clinical diagnosis
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter (normal = 0 mmHg; elevated ≥30 mmHg or [measured pressure – dBP] ≤30 mmHg)

## Treatment

- non-operative
  - remove constrictive dressings (casts, splints), elevate limb at the level of the heart
- operative
  - urgent fasciotomy
  - 48-72 h post-operative: necrotic tissue debridement + wound closure
  - may require delayed closure and/or skin grafting

## Complications

- Volkmann's ischemic contracture: ischemic necrosis of muscle; followed by secondary fibrosis; and finally calcification - especially following supracondylar fracture of humerus
- rhabdomyolysis, renal failure secondary to myoglobinuria

# Osteomyelitis

- bone infection with progressive inflammatory destruction

## Etiology

- most commonly caused by *S. aureus*
- mechanism of spread: hematogenous (most common) vs. direct-inoculation vs. contiguous focus
- risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

**Plain Film Findings of Osteomyelitis**
- Soft tissue swelling
- Lytic bone destruction*
- Periosteal reaction (formation of new bone, especially in response to #)*

*Generally not seen on plain films until 10-12 d after onset of infection

### Clinical Features
- symptoms: pain and fever
- on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

### Diagnosis
- see Medical Imaging, MI23
- workup includes: WBC and differential, ESR, CRP, blood culture, aspirate culture/bone biopsy

**Table 7. Treatment of Osteomyelitis**

| Acute Osteomyelitis | Chronic Osteomyelitis |
|---|---|
| IV antibiotics 4-6 wk; started empirically and adjusted after obtaining blood and aspirate cultures | Surgical debridement |
| ± surgery (I&D) for abscess or significant involvement | Antibiotics: both local (e.g. antibiotic beads) and systemic (IV) |
| ± hardware removal (if present) | |

Rapid progression of signs and symptoms (over hours) necessitates need for serial examinations

Acute osteomyelitis is a medical emergency which requires an early diagnosis and appropriate antimicrobial and surgical treatment

## Septic Joint

- joint infection with progressive destruction if left untreated

### Etiology
- most commonly caused by *S. aureus* in adults
- consider coagulase-negative Staphylococcus in patients with prior joint replacement
- consider *N. gonorrhoeae* in sexually active adults and newborns
- most common route of infection is hematogenous
- risk factors: young/elderly (age >80 yr), prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, recent intra-articular corticosteroid injection, immunocompromised (cancer, DM, alcoholism, RA)

### Clinical Features
- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

### Investigations
- X-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: cloudy yellow fluid, WBC >50,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level <60% blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (re: concern for infective endocarditis, use Duke Criteria)

### Treatment
- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- non-operative
  - therapeutic joint aspiration, serially if necessary
- operative
  - arthroscopic/open irrigation and drainage

Most commonly affected joints in descending order
knee → hip → elbow → ankle → sternoclavicular joint

**Plain Film Findings in a Septic Joint**
- Early (0-3 d): usually normal; may show soft-tissue swelling or joint space widening from localized edema
- Late (4-6 d): joint space narrowing and destruction of cartilage

Serial C-reactive protein (CRP) can be used to monitor response to therapy

**Does This Adult Patient Have Septic Arthritis?**
JAMA 2007;297(13):1478-88
**Purpose**: To review the accuracy and precision of the clinical evaluation for the diagnosis of nongonococcal bacterial arthritis.
**Methods**: Review of 14 studies including 6242 patients of which 653 had positive synovial culture (gold standard diagnostic tool for septic arthritis).
**Results/Conclusions**: Age, diabetes mellitus, rheumatoid arthritis, joint surgery, hip or knee prosthesis, skin infection, and human immunodeficiency virus type 1 infection significantly increase the probability of septic arthritis. Joint pain, history of joint swelling, and fever are useful clinical findings in identifying patients with a monoarticular arthritis who may have septic arthritis. Laboratory findings from an arthrocentesis are also required and helpful prior to Gram stain and culture. The presence of increased WBC increases the likelihood ratio (for counts <25 000/μL: LR, 0.32; 95% CI, 0.23-0.43; for counts ≥25 000/μL: LR, 2.9; 95% CI, 2.5-3.4; for counts ≥100 000/μL: LR, 28.0; 95% CI, 12.0-66.0). A polymorphonuclear cell count of ≥90% increases the LR of septic arthritis by 3.4, while a PMN cell count of <90% reduces the LR by 0.34.

# Shoulder

## Shoulder Dislocation

- complete loss of continuity between the two articular surfaces of the glenohumeral joint; may be anterior or posterior

### Investigations
- anterior dislocation X-rays: AP, trans-scapular, and axillary views of the shoulder
- posterior dislocation X-rays: AP, trans-scapular, and axillary views of the shoulder; or CT scan

**Posterior Shoulder Dislocation**
Up to 60-80% are missed on initial presentation due to poor physical exam and radiographs

**There are 4 Joints in the Shoulder**
Glenohumeral, AC, sternoclavicular (SC), scapulothoracic

## Table 8. Anterior and Posterior Shoulder Dislocation

| | Anterior Shoulder Dislocation (>90%) | Posterior Shoulder Dislocation (5%) |
|---|---|---|
| **MECHANISM** | | |
| | Abducted arm is externally rotated/hyperextended<br>Blow to posterior shoulder<br>Involuntary, usually traumatic; voluntary, atraumatic | Adducted, internally rotated, flexed arm<br>FOOSH<br>3 Es (epileptic seizure, EtOH, electrocution)<br>Blow to anterior shoulder |
| **CLINICAL FEATURES** | | |
| **Symptoms** | Pain, arm slightly abducted and externally rotated with inability to internally rotate | Pain, arm is held in adduction and internal rotation; external rotation is blocked |
| **Shoulder Exam** | **"Squared off" shoulder**<br>**Positive apprehension test**: patient looks apprehensive with gentle shoulder abduction and external rotation to 90° as humeral head is pushed anteriorly and recreates feeling of anterior dislocation<br>**Positive relocation test**: a posteriorly directed force applied during the apprehension test relieves apprehension since anterior subluxation is prevented<br>**Positive sulcus sign**: presence of subacromial indentation with distal traction on humerus indicates inferior shoulder instability | **Anterior shoulder flattening**, prominent coracoid, palpable mass posterior to shoulder<br>**Positive posterior apprehension ("jerk") test**: with patient supine, flex elbow 90° and adduct, internally rotate the arm while applying a posterior force to the shoulder; patient will "jerk" back with the sensation of subluxation<br>Note: the posterior apprehension test is used to test for recurrent posterior instability, NOT for acute injury |
| **Neurovascular Exam Including** | Axillary nerve: sensory patch over deltoid and deltoid contraction<br>Musculocutaneous nerve: sensory patch on lateral forearm and biceps contraction | Full neurovascular exam as per anterior shoulder dislocation |
| **RADIOGRAPHIC FINDINGS** | | |
| **Axillary View** | Humeral head is anterior | Humeral head is posterior |
| **Trans-scapular 'Y' View** | Humeral head is anterior to the centre of the "Mercedes-Benz" sign | Humeral head is posterior to centre of "Mercedes-Benz" sign |
| **AP View** | Sub-coracoid lie of the humeral head is most common | Partial vacancy of glenoid fossa (vacant glenoid sign) and >6 mm space between anterior glenoid rim and humeral head (positive rim sign), humeral head may resemble a lightbulb due to internal rotation (lightbulb sign) |
| **Hill-Sachs and Bony Bankart Lesions** | ± Hill-Sachs lesion: compression fracture of posterior humeral head due to forceful impaction of an anteriorly dislocated humeral head against the glenoid rim<br>± bony Bankart lesion: avulsion of the anterior glenoid labrum (with attached bone fragments) from the glenoid rim | ± **Reverse Hill-Sachs lesion** (75% of cases): divot in anterior humeral head<br>± **Reverse bony Bankart lesion**: avulsion of the posterior glenoid labrum from the bony glenoid rim |
| **TREATMENT** | | |
| | Closed reduction with IV sedation and muscle relaxation<br>**Traction-countertraction**: assistant stabilizes torso with a folded sheet wrapped across the chest while the surgeon applies gentle steady traction<br>**Stimson:** while patient lies prone with arm hanging over table edge, hang a 5 lb weight on wrist for 15-20 min<br>**Hippocratic method**: place heel into patient's axilla and apply traction to arm<br>**Cunningham's method**: low risk, low pain; if not successful try above methods<br>Obtain post-reduction x-rays<br>Check post-reduction NVS<br>Sling x 3 wk (avoid abduction and external rotation), followed by shoulder rehabilitation (dynamic stabilizer strengthening) | Closed reduction with sedation and muscle relaxation<br>Inferior traction on a flexed elbow with pressure on the back of the humeral head<br>Obtain post-reduction x-rays<br>Check post-reduction NVS<br>Sling in abduction and external rotation x 3 wk, followed by shoulder rehabilitation (dynamic stabilizer strengthening) |

## Prognosis

- recurrence rate depends on age of first dislocation
- <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

## Specific Complications

- recurrent/unreduced dislocation (most common complication)
- rotator cuff or capsular or labral tear (Bankart/SLAP lesion), shoulder stiffness
- injury to axillary nerve/artery, brachial plexus

**Shoulder passive ROM**: abduction – 180°, adduction – 45°, flexion – 180°, extension – 45°, int. rotation – level of T4, ext. rotation – 40-45°

**Factors Causing Shoulder Instability**

- Shallow glenoid
- Loose capsule
- Ligamentous laxity

**Frequency of Dislocations**

- Anterior shoulder > Posterior shoulder
- Posterior hip > Anterior hip

The glenohumeral joint is the most commonly dislocated joint in the body since stability is sacrificed for motion

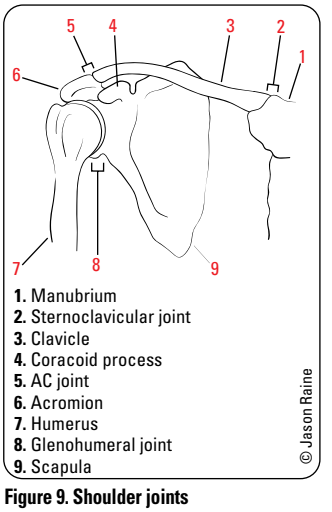

**Figure 9. Shoulder joints**

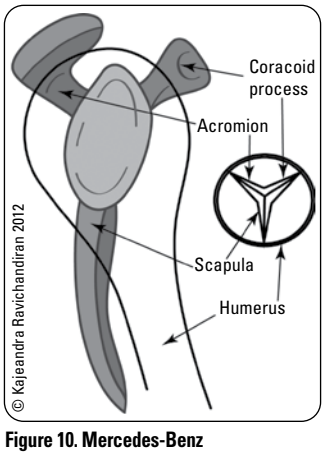

**Figure 10. Mercedes-Benz**

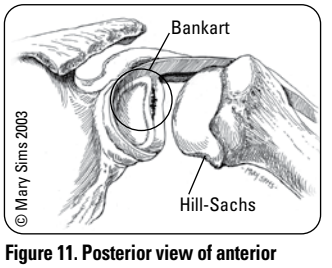

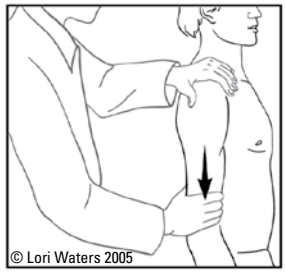

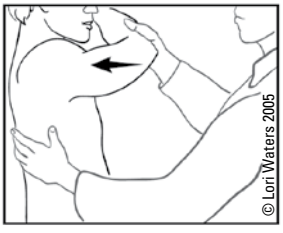

**Figure 11. Posterior view of anterior dislocation causing Hill-Sachs and Bankart lesions**

Anterior apprehension sign

Sulcus sign

Posterior apprehension sign

Traction-Countertraction

**Figure 12. Shoulder maneuvers**

# Rotator Cuff Disease

- rotator cuff consists of 4 muscles that act to stabilize the humeral head within the glenoid fossa

**Table 9. Rotator Cuff Muscles (SITS)**

| Muscle | Muscle Attachments | | Nerve Supply | Muscle Function |
|---|---|---|---|---|
| | Proximal | Distal | | |
| **Supraspinatus** | Scapula | Greater tuberosity of humerus | Suprascapular nerve | Abduction |
| **Infraspinatus** | Scapula | Greater tuberosity of humerus | Suprascapular nerve | External rotation |
| **Teres Minor** | Scapula | Greater tuberosity of humerus | Axillary nerve | External rotation |
| **Subscapularis** | Scapula | Lesser tuberosity of humerus | Subscapular nerve | Internal rotation and adduction |

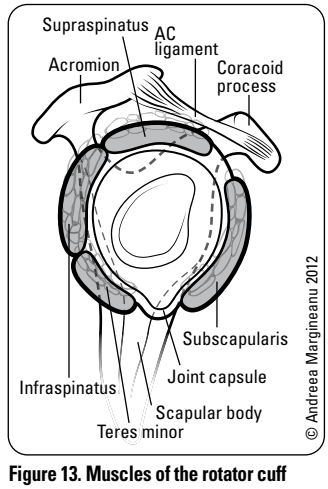

**Figure 13. Muscles of the rotator cuff**

## SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

### Etiology

- anything that leads to a narrow subacromial space
- most commonly, a relative imbalance of rotator cuff and larger shoulder muscles, allowing for superior translation and subsequent wear of the rotator cuff muscle tendons
  - glenohumeral muscle weakness leading to abnormal motion of humeral head
  - scapular muscle weakness leading to abnormal motion of acromion
- acromial abnormalities, such as congenital narrow space or osteophyte formation or Type III acromion morphology
  1. outlet/subacromial impingement: "painful arc syndrome", compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint, and CA ligament
  2. bursitis and tendonitis
  3. rotator cuff thinning and tear if left untreated

### Clinical Features

- insidious onset, but may present as an acute exacerbation of chronic disease, night pain, and difficulty sleeping on affected side
- pain worsens with active motion (especially overhead); passive movement generally permitted
- weakness and loss of ROM, especially between 90°-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed's test; SLAP lesion: O'Brien's test

### Investigations

- X-ray: AP view may show high riding humerus relative to glenoid, indicating large tear, evidence of chronic tendonitis
- MRI: coronal/sagittal, oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: can assess full thickness tears, difficult to assess partial tears

**Bigliani Classification of Acromion Morphology**
- Type I – flat
- Type II – curved
- Type III – hooked

**Screening Out Rotator Cuff Tears***
- No night pain (SN 87.7%)
- No painful arc (SN 97.5%)
- No impingement signs (SN 97.2%)
- No weakness

*Returning to the bedside: Using the history and physical examination to identify rotator cuff tears
JAM Geri Soc 2000;48:1633-7

## Treatment

- non-operative
  - mild or moderate cases
  - physiotherapy, NSAIDs ± steroid injection
  - all rotator cuff injury treatment begins with physiotherapy (regardless of severity on MRI findings), with progression to surgery if necessary
- operative
  - severe tear or impingement that is refractory to 2-3 mo physiotherapy and 1-2 corticosteroid injections
  - arthroscopic or open surgical repair (i.e. acromioplasty, rotator cuff repair)

**Ruling in Rotator Cuff Tears – 98% probability of rotator cuff tear if all** 3 of the following are present:
- Supraspinatus weakness
- External rotation weakness
- Positive impingement sign(s)

Diagnosis of rotator cuff tears.
Lancet 2001; 357:769-70

**Does this Patient with Shoulder Pain have Rotator Cuff Disease? The Rational Clinical Examination Systematic Review**
JAMA 2013;310:837-847
**Study**: 5 studies of sufficient quality including 30-203 shoulders and a prevalence of RCD ranging from 33-81%.
**Results/Conclusions**: Among pain provocation tests, a positive painful arc test had the greatest specificity and sensitivity (SP 81%, SN 71%). Among strength tests, a positive external rotation lag test and internal rotation lag test were the most accurate for full-thickness tears (SP 47%, SN 94%; SP 97%, SN 83% respectively). The internal rotation lag test was therefore also the most accurate for identifying patients without a full-thickness tear.
A positive drop arm test is helpful to identify patients with RCD (SN 24%, SP 93%).

### Table 10. Rotator Cuff Special Tests

| Test | Examination | Positive Test |
|---|---|---|
| **Jobe's Test (i.e. Empty Can Test)** | Supraspinatus: place the shoulder in 90° of abduction and 30° of forward flexion and internally rotate the arm so that the thumb is pointing toward the floor | Weakness with active resistance suggests a supraspinatus tear |
| **Lift-off Test** | Subscapularis: internally rotate arm so dorsal surface of hand rests on lower back; patient instructed to actively lift hand away from back against examiner resistance (use Belly Press Test if too painful) | Inability to actively lift hand away from back suggests a subscapularis tear |
| **Posterior-Cuff Test** | Infraspinatus and teres minor: arm positioned at patient's side in 90° of flexion; patient instructed to externally rotate arm against the resistance of the examiner | Weakness with active resistance suggests posterior cuff tear |
| **Neer's Test** | Rotator cuff impingement: passive shoulder flexion | Pain elicited between 130-170° suggests impingement |
| **Hawkins-Kennedy Test** | Rotator cuff impingement: shoulder flexion to 90° and passive internal rotation | Pain with internal rotation suggests impingement |
| **Painful Arc Test** | Rotator cuff tendinopathy: patient instructed to actively abduct the shoulder | Pain with abduction >90° suggests tendinopathy |
| **Speed's Test** | Apply resistance to the forearm when the arm is in forward flexion with the elbows fully extended. | Pain in the bicipital groove |
| **O'Brien's Test** | SLAP lesion: forward flexion of the arm to 90 degrees while keeping the arm extended. Arm is adducted 10-15 degrees. Internally rotate the arm so thumb is facing down and apply a downward force. Repeat the test with arm externally rotated | Pain or clicking in the glenohumoral joint in internal rotation but not external rotation |

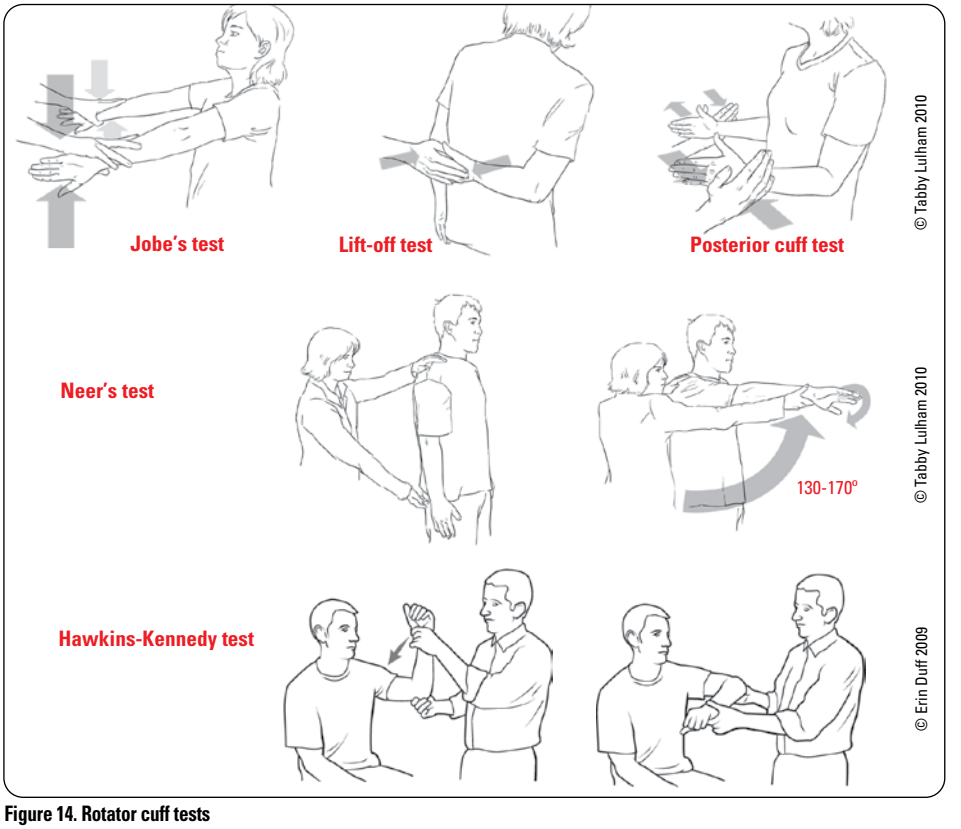

**Figure 14. Rotator cuff tests**

# Acromioclavicular Joint Pathology

- subluxation or dislocation of AC joint
- 2 main ligaments attach clavicle to scapula: AC and CC ligaments

### Mechanism
- fall onto shoulder with adducted arm or direct trauma to point of shoulder

### Clinical Features
- pain with adduction of shoulder and/or palpation over AC joint
- palpable step deformity between distal clavicle and acromion (with dislocation) i.e. piano key sign
- limited ROM

### Investigations
- X-rays: bilateral AP, Zanca view (10-15° cephalic tilt), axillary

### Treatment
- non-operative
  - sling 1-3 wk, ice, analgesia, early ROM and rehabilitation
- operative
  - indication: Rockwood Class IV-VI (III if labourer or high level athlete)
  - number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

Pneumothorax or pulmonary contusion are potential complications of severe clavicle fracture, and rarely severe AC joint dislocation

**Table 11. Rockwood Classification of Acromioclavicular Joint Separation**

| Grade | Features | Treatment |
|---|---|---|
| I | Joint sprain, absence of complete tear of either ligament | Non-operative |
| II | Complete tear of AC ligament, incomplete tear of CC ligament, without marked elevation of lateral clavicular head | Non-operative |
| III | Complete tear of AC and CC ligaments, >5 mm elevation at AC joint, superior aspect of acromion is below the inferior aspect of the clavicle | Most non-operative, operative if labourer or high level athlete<br>Will heal with step deformity, although most fully functional in 4-6 mo |
| IV-VI | Based on the anatomical structure the displaced clavicle is in proximity to | Operative in most cases |

| Grade | AC Ligament | CC Ligament | Reducible | Treatment |
|---|---|---|---|---|
| I | Sprained | Normal | N/A | Non-operative |
| II | Torn | Sprained | Yes | Non-operative |
| III | Torn | Torn | Yes | Most non-operative, operative if labourer or high-level athlete<br>Will heal with step deformity, although most fully functional in 4-6 mo |
| IV-VI | Torn | Torn | No | Operative in most cases |

Rockwood separations IV-VI are determined based on direction of displacement:
IV: Distal clavicle displaced posteriorly into trapezius (seen on axillary XR)
V: Distal clavicle herniated through deltotrapezial fascia into subcutaneous tissue
VI: Distal clavicle displaced inferior to acromion or coracoid under conjoined tendon (rare)

# Clavicle Fracture

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

### Mechanism
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

### Clinical Features
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

### Investigations
- evaluate NVS of entire upper limb
- X-ray: AP, 45° cephalic tilt (superior/inferior displacement), 45° caudal tilt (AP displacement)
- CT: useful for medial physeal fractures and sternoclavicular injury

**Non-Operative Treatment Compared with Plate Fixation of Displaced Mid-Shaft Clavicular Fractures. A Multicentre, Randomized Clinical Trial**
J Bone Joint Surg. Am. 2007; 89(1),1-10
**Purpose**: To compare non-operative treatment with plate fixation in displaced mid-shaft clavicular fractures.
**Results**: Constant shoulder scores and DASH scores were significantly improved in the operative fixation group at all time-points ($p = 0.001$ and $p < 0.01$, respectively). The mean time to radiographic union was 28.4 weeks in the non-operative group compared with 16.4 weeks in the operative group ($p = 0.001$). At one year after the injury, the patients in the operative group were more likely to be satisfied with the appearance of the shoulder ($p = 0.001$) and with the shoulder in general ($p = 0.002$) than were those in the non-operative group.
**Conclusions**: Operative fixation of a displaced fracture of the clavicular shaft results in improved functional outcome and a lower rate of malunion and nonunion compared with non-operative treatment at one year of follow-up.

### Treatment
- medial and middle-third clavicle fractures
  - for nondisplaced fractures, simple sling x 1-2 wk prn
  - early ROM and strengthening once pain subsides
  - if fracture is shortened >2 cm, consider ORIF
- distal-third clavicle fractures
  - undisplaced (with ligaments intact): sling x 1-2 wk
  - displaced (CC ligament injury): ORIF

**Associated Injuries with Clavicle Fractures**
- Up to 9% of clavicle fractures are associated with other fractures (most commonly rib fractures)
- Majority of brachial plexus injuries are associated with proximal third fractures

### Specific Complications (see *General Fracture Complications*, OR7)
- cosmetic bump usually only complication
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)

## Frozen Shoulder (Adhesive Capsulitis)

- disorder characterized by progressive pain and stiffness of the shoulder, usually resolving spontaneously after 18 mo

### Mechanism
- primary adhesive capsulitis
  - idiopathic, often associated with DM
  - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
  - due to prolonged immobilization
  - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
  - following MI, stroke, shoulder trauma
  - poorer outcomes

**Conditions Associated with an Increased Incidence of Adhesive Capsulitis**
- Prolonged immobilization (most significant)
- Female gender
- Age >49 yr
- DM (5x)
- Cervical disc disease
- Hyperthyroidism
- Stroke
- MI
- Trauma and surgery
- Autoimmune disease

### Clinical Features
- gradual onset (weeks to months) of diffuse shoulder pain with:
  - decreased active AND passive ROM
  - pain worse at night and often prevents sleeping on affected side
  - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

**Stages of Adhesive Capsulitis**
1. Freezing phase: gradual onset, diffuse pain (lasts 6-9 mo)
2. Frozen phase: decreased ROM impacts function (lasts 4-9 mo)
3. Thawing phase: gradual return of motion (lasts 5-26 mo)

### Investigations
- X-ray: AP (neutral, internal/external rotation), scapular Y, and axillary views of the shoulder
  - may be normal, or may show demineralization from disease

### Treatment
- freezing phase
  - active and passive ROM (physiotherapy)
    - NSAIDs and steroid injections if limited by pain
- thawing phase
  - manipulation under anesthesia and early physiotherapy
    - arthroscopy for debridement/decompression

# Humerus

## Proximal Humeral Fracture

### Mechanism
- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

### Clinical Features
- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm and chest

### Investigations
- test axillary nerve function (deltoid contraction and skin over deltoid)
- X-rays: AP, trans-scapular, and axillary views of the shoulder are essential
- CT scan: to evaluate for articular involvement and fracture displacement

### Classification
- Neer classification is based on 4 fracture locations or 'parts'
- displaced: displacement >1 cm and/or angulation >45°
- the Neer system regards the number of displaced fractures, not the fracture line, in determining classification
- ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

**Neer Classification**
**Based on 4 parts of humerus**
- Greater Tuberosity
- Lesser Tuberosity
- Humeral Head
- Shaft

**One-part fracture**: any of the 4 parts with none displaced
**Two-part fracture**: any of the 4 parts with 1 displaced
**Three-part fracture**: displaced fracture of surgical neck + displaced greater tuberosity or lesser tuberosity
**Four-part fracture**: displaced fracture of surgical neck + both tuberosities

### Treatment
- assess for and treat osteoporosis if needed
- non-operative
  - nondisplaced and minimally displaced (85% of patients): broad arm sling immobilization, begin ROM within 14 d to prevent stiffness
  - most displaced fractures in low-demand elderly patients
- operative
  - ORIF (anatomic neck fractures, displaced, associated irreducible glenohumeral joint dislocation)
  - hemiarthroplasty or reverse TSA may be necessary, especially in elderly

### Specific Complications (see *General Fracture Complications*, OR7)
- AVN, nerve palsy (45%; typically axillary nerve), malunion, post-traumatic arthritis, persistent pain and weakness, frozen shoulder

## Humeral Shaft Fracture

### Mechanism
- high energy: direct blows/MVC (especially young); low energy: FOOSH, twisting injuries, metastases (in elderly)

### Clinical Features
- pain, swelling, weakness ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment in dorsum of hand

### Investigations
- X-ray: AP and lateral views of the humerus, including the shoulder and elbow joints

### Treatment
- in general, humeral shaft fractures are treated non-operatively
- non-operative
  - ± reduction; can accept deformity due to compensatory ROM of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: see *"NO CAST"* OR6, pathological fracture, "floating elbow" (simultaneous unstable humeral and forearm fractures)
  - ORIF: plating (most common), IM rod insertion, external fixation

### Specific Complications (see *General Fracture Complications*, OR7)
- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

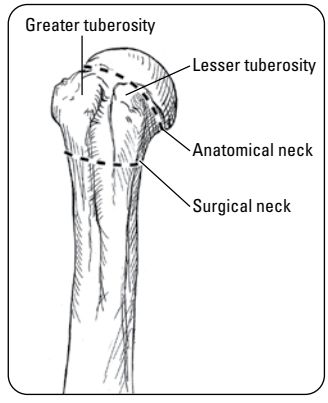

**Figure 15. Fractures of the proximal humerus**

**Acceptable Humeral Shaft Deformities for Non-Operative Treatment**
- <20° anterior angulation
- <30° varus angulation
- <3 cm of shortening

Risk of radial nerve and brachial artery injury

## Distal Humeral Fracture

### Mechanism
- young: high energy trauma (MVC)
- elderly: FOOSH

### Clinical Features
- elbow pain and swelling
- assess brachial artery

### Investigations
- X-ray: AP and lateral views of the humerus and elbow
- CT scan: helpful when suspecting shear fracture of capitulum or trochlea
- assess NVS: radial, ulnar and median nerve

### Classification
- supracondylar, distal single column, distal bicolumnar, and coronal shear fractures

### Treatment
- goal is to restore ROM to 30-130° flexion (unsatisfactory outcomes in 25%)
- non-operative (pediatric patients only)
  - cast immobilization (in supination for lateral condyle fracture; pronation for medial condyle fractures)
- operative
  - indications: displaced, supracondylar, bicolumnar
  - closed reduction and percutaneous pinning (children); ORIF; total elbow arthroplasty (bicolumnar in elderly)
  - adult fractures are almost always treated operatively due to risk of elbow stiffness with non-operative management

The anterior humeral line refers to an imaginary line drawn along the anterior surface of the humeral cortex that passes through the middle third of the capitellum when extended inferiorly. In subtle supracondylar fractures, the anterior humeral line is disrupted, typically passing through the anterior third of the capitellum

# Elbow

## Supracondylar Fracture

- subclass of distal humerus fracture: extra-articular, fracture proximal to capitulum and trochlea, usually transverse
- most common in pediatric population (peak age ~7 yr old), rarely seen in adults
- AIN (median nerve) injury commonly associated with extension type

### Mechanism
- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

### Clinical Features
- pain, swelling, point tenderness
- neurovascular injury: median and radial nerves, radial artery

### Investigations
- X-ray: AP and lateral views of the elbow
  - disruption of anterior humeral line suggests supracondylar fracture
  - fat pad sign: a sign of effusion and can be indicative of occult fracture
  - assess NVS: median and radial nerves, radial artery

### Treatment
- non-operative
  - nondisplaced (pediatric): long arm plaster slab in 90° flexion x 3 wk
- operative
  - indications: displaced >50%, vascular injury, open fracture
  - requires percutaneous pinning followed by limb cast with elbow flexed <90°
  - in adults, ORIF is necessary

### Specific Complications (see *General Fracture Complications*, OR7)
- stiffness is most common
- brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann's ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

**Three Joints at the Elbow**
- Humeroradial joint
- Humeroulnar joint
- Radioulnar joint

Normal carrying angle of elbow is ~10° of valgus

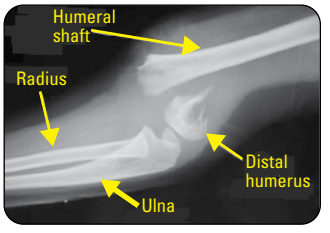

**Figure 16. X-ray of transverse displaced supracondylar fracture of humerus with elbow dislocation**

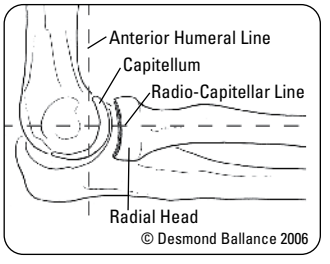

**Figure 17. Lateral view of elbow**

## Radial Head Fracture

- a common fracture of the upper limb in young adults

### Mechanism
- FOOSH with elbow extended and forearm pronated

### Clinical Features
- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, ± mechanical block to forearm pronation and supination
- pain on pronation/supination

### Investigations (Figure 18)
- X-ray: AP and lateral views of the elbow
  - enlarged anterior fat pad ("sail sign") or the presence of a posterior fat pad on lateral view indicates effusion, which could occur with occult radial head fractures

**Table 12. Classification and Treatment of Radial Head Fractures**

| Mason Class | Radiographic Description | Treatment |
|---|---|---|
| 1 | Nondisplaced fracture | Elbow slab or sling x 3-5 d with early ROM |
| 2 | Displaced fracture | ORIF if: angulation >30°, involves ≥1/3 of the radial head, or if ≥3 mm of joint incongruity exists |
| 3 | Comminuted fracture | Radial head excision ± prosthesis (if ORIF not feasible) |
| 4 | Comminuted fracture with posterior elbow dislocation | Radial head excision ± prosthesis |

### Specific Complications (see *General Fracture Complications*, OR7)
- myositis ossificans – calcification of muscle
- recurrent instability (if MCL injured and radial head excised)

**Terrible Triad**
- Radial head fracture
- Coronoid fracture
- Elbow dislocation

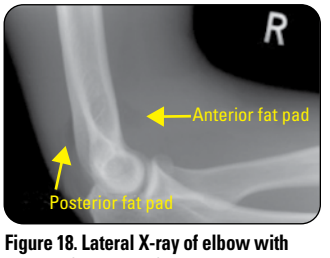

**Figure 18. Lateral X-ray of elbow with effusion ("sail sign")**

To avoid stiffness, do not immobilize elbow joint >2-3 wk

# Olecranon Fracture

### Mechanism
- direct trauma to posterior aspect of elbow (fall onto the point of the elbow) or FOOSH

### Clinical Features
- localized pain, palpable defect
- ± loss of active extension due to avulsion of triceps tendon

### Investigations
- X-ray: AP and lateral (require true lateral to determine fracture pattern)

### Treatment
- non-operative
  - non-displaced (<2 mm, stable): cast x 2-3 wk (elbow in 90° flexion), then gentle ROM
- operative
  - displaced: ORIF (plate and screws or tension-band wiring) and early ROM if stable

# Elbow Dislocation

- third most common joint dislocation after shoulder and patella
- anterior capsule and collateral ligaments disrupted

**Elbow Dislocation**
The radio-capitellar line refers to an imaginary line along the longitudinal axis of the radial neck that passes through the centre of the capitellum, regardless of the degree of elbow flexion. If the radio-capitellar line does not pass through the centre of the capitellum a dislocation should be suspected

### Mechanism
- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
- usually the radius and ulna are dislocated together, alternatively the radial head dislocates in isolation and the ulna is fractured ("Monteggia Fracture")
- 80% are posterior/posterolateral, anterior are rare and usually devastating

### Clinical Features
- elbow pain, swelling, deformity
- flexion contracture
- ± absent radial or ulnar pulses

### Investigations
- X-ray: AP and lateral views of the elbow
- assess NVS: brachial artery, median and ulnar nerves

### Treatment
- non-operative
  - closed reduction under conscious sedation (post-reduction x-rays required)
  - Parvin's method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist; as olecranon slips distally, gently lift up the arm at elbow to reduce joint
  - long-arm splint with forearm in neutral rotation and elbow in 90° flexion
  - early ROM (<2 wk)
- operative
  - indications: complex dislocation or persistent instability after closed reduction
  - ORIF

### Specific Complications (see *General Fracture Complications*, OR7)
- stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
- recurrent instability uncommon

# Epicondylitis

- lateral epicondylitis = "tennis elbow", inflammation of the common extensor tendon as it inserts into the lateral epicondyle
- medial epicondylitis = "golfer's elbow", inflammation of the common flexor tendon as it inserts into the medial epicondyle

**T**ennis Elbow = la**T**eral epicondylitis; pain associated with ex**T**ension of wrist

### Mechanism
- repeated or sustained contraction of the forearm muscles/chronic overuse

### Clinical Features
- point tenderness over humeral epicondyle and/or distal to it
- pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
- generally a self-limited condition, but may take 6-18 mo to resolve

### Treatment
- non-operative (very good outcomes)
  - rest, ice, NSAIDs
  - use brace/strap
  - physiotherapy, stretching, and strengthening
  - corticosteroid injection
- operative
  - indication: failed 6-12 mo conservative therapy
  - percutaneous or open release of common tendon from epicondyle

**Elbow Joint Injection**
Inject at the centre of the triangle formed by the lateral epicondyle, radial head, and olecranon

# Forearm

## Radius and Ulna Shaft Fractures

### Mechanism
- high-energy direct or indirect (MVA, fall from height, sports) trauma
- fractures usually accompanied by displacement due to high force

### Clinical Features
- deformity, pain, swelling
- loss of function in hand and forearm

### Investigations
- X-ray: AP and lateral of forearm ± oblique of elbow and wrist
- CT if fracture is close to joint

### Treatment
- goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
- ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

### Specific Complications (see *General Fracture Complications*, OR7)
- soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

## Monteggia Fracture

- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury
- more common and better prognosis in the pediatric age group when compared to adults

### Mechanism
- direct blow to the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

### Clinical Features
- pain, swelling, decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

### Investigations
- X-ray: AP and lateral views of the elbow, wrist and forearm

### Treatment
- adults: ORIF of ulna with indirect reduction of radiocapitellar joint in 90% of patients (open reduction of radiocapitellar joint if unsuccessful)
- splint and early post-operative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 2-3 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

### Specific Complications (see *General Fracture Complications*, OR7)
- PIN injury: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis

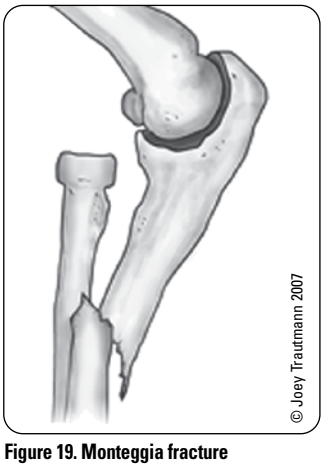

**Figure 19. Monteggia fracture**

In all isolated ulna fractures, assess proximal radius to rule out a Monteggia fracture

**Bado Type Classification of Monteggia Fractures**
Based on the direction of displacement of the dislocated radial head, generally the same direction as the apex of the ulnar fracture
Type I: anterior dislocation of radial head and proximal/middle third ulnar fracture (60%)
Type II: posterior dislocation of radial head and proximal/middle third ulnar fracture (15%)
Type III: lateral dislocation of radial head and metaphyseal ulnar fracture (20%)
Type IV – combined: proximal fracture of the ulna and radius, dislocation of the radial head in any direction (<5%)

## Nightstick Fracture

- isolated fracture of ulna without dislocation of radial head

### Mechanism
- direct blow to forearm (e.g. holding arm up to protect face)

### Treatment
- non-operative
  - indication: non-displaced
  - below elbow cast (x 10 d), followed by forearm brace (~8 wk)
- operative
  - indication: significantly displaced
  - ORIF if >50% shaft displacement or >10° angulation

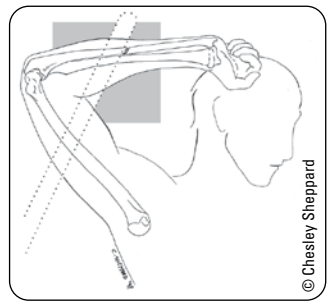

**Figure 20. Nightstick fracture**

## Galeazzi Fracture

- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis

### Mechanism
- hand FOOSH with axial loading of pronated forearm or direct wrist trauma

### Clinical Features
- pain, swelling, deformity, and point tenderness at fracture site

### Investigations
- X-ray: AP, and lateral views of the elbow, wrist, and forearm
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

### Treatment
- all cases are operative
  - ORIF of radius; afterwards, assess DRUJ stability by balloting distal ulna relative to distal radius
  - if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
  - if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 2-3 wk

For all isolated radius fractures assess DRUJ to rule out a Galeazzi fracture

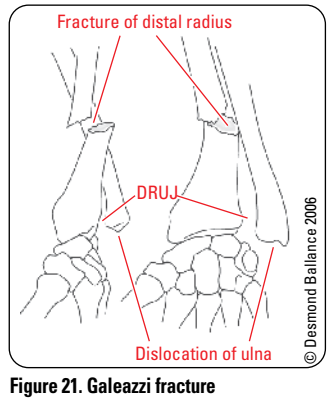

**Figure 21. Galeazzi fracture**

# Wrist

## Colles' Fracture

- extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture
- most common fracture in those >40 yr, especially in women and those with osteoporotic bone

### Mechanism
- FOOSH

### Clinical Features
- "dinner fork" deformity
- swelling, ecchymosis, tenderness

### Investigations
- X-ray: AP and lateral views of the wrist

### Treatment
- goal is to restore radial height (13 mm), radial inclination (22°), volar tilt (11°), as well as DRUJ stability and useful forearm rotation
- non-operative
  - closed reduction (think opposite of the deformity)
  - hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
  - closed reduction: traction with extension (exaggerate injury); traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
  - dorsal slab/below elbow cast for 5-6 wk
  - obtain post-reduction films immediately; repeat reduction if necessary
  - x-ray at 1 wk, 3 wk, and at cessation of immobilization to ensure reduction is maintained

**Indications for Direct Surgical Management of Colles' Fracture**
- Displaced intra-articular fracture
- Comminuted
- Severe osteoporosis
- Dorsal angulation >5° or volar tilt >20°
- >5 mm radial shortening

**Features of Inadequate Closed Reduction that Require ORIF**
- Radial shortening >3 mm or,
- Dorsal tilt >10° or,
- Intra-articular displacement/step-off >2 mm

- operative
  - indication: failed closed reduction, or loss of reduction
  - percutaneous pinning, external fixation, or ORIF

# Smith's Fracture

- volar displacement of the distal radius (i.e. reverse Colles' fracture)

### Mechanism
- fall onto the back of the flexed hand

### Investigations
- X-ray: AP and lateral views of the wrist

### Treatment
- usually unstable and needs ORIF
- if patient is poor operative candidate, may attempt non-operative treatment
  - closed reduction with hematoma block (reduction opposite of Colles')
  - long-arm cast in supination x 6 wk

# Complications of Wrist Fractures

- most common complications are poor grip strength, stiffness, and radial shortening
- distal radius fractures in individuals <40 yr of age are usually highly comminuted and are more likely to require ORIF
- 80% have normal function in 6-12 mo

**Table 13. Early and Late Complications of Wrist Fractures**

| Early | Late |
|---|---|
| Difficult reduction ± loss of reduction | Malunion, radial shortening |
| Compartment syndrome | Painful wrist secondary to ulnar prominence |
| Extensor pollicis longus tendon rupture | Frozen shoulder ("shoulder-hand syndrome") |
| Acute carpal tunnel syndrome | Post-traumatic arthritis |
| Finger swelling with venous block | Carpal tunnel syndrome |
| Complications of a tight cast/splint | CRPS/RSD |

# Scaphoid Fracture

### Epidemiology
- most common carpal bone injured
- common in young men; not common in children or in patients beyond middle age
- may be associated with other carpal or wrist injuries (e.g. Colles' fracture)

### Mechanism
- FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), distal (10%), or proximal (25%) scaphoid

### Clinical Features
- pain with resisted pronation
- tenderness in the anatomical "snuff box", over scaphoid tubercle, and pain with long axis compression into scaphoid
- usually nondisplaced

### Investigations
- X-ray: AP, lateral, and scaphoid views with wrist extension and ulnar deviation
- ± CT or MRI: detect occult fracture and prevent AVN
- bone scan rarely used
  - note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative, order CT or MRI

### Treatment
- early treatment critical for improving outcomes
- non-operative
  - non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk, then short arm cast until radiographic evidence of healing is seen (2-3 mo)
- operative
  - displaced: ORIF with headless/countersink compression screw is the mainstay treatment

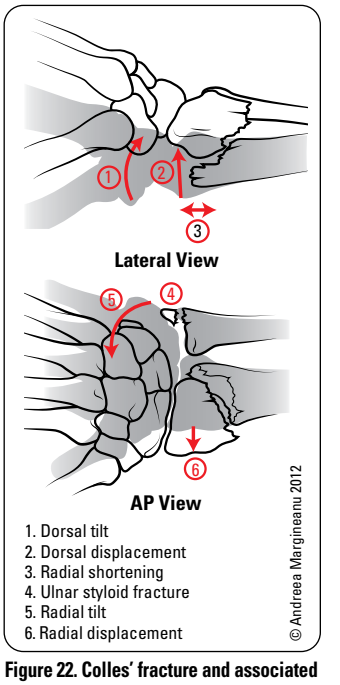

**Figure 22. Colles' fracture and associated bony deformity**

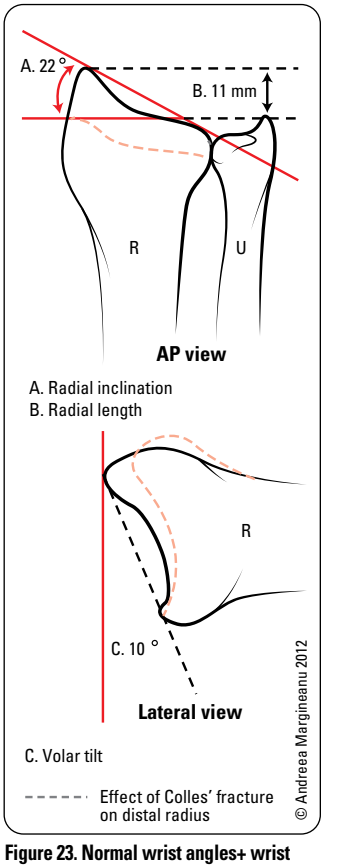

**Figure 23. Normal wrist angles+ wrist angles in Colles' fracture**
Note the relative shortening of the radius relative to the ulna on AP view in Colles' fracture

**Scaphoid Fracture Special Tests**
Tender snuff box: 100% sensitivity, but 29% specific, as it is also positive with many other injuries of radial aspect of wrist with FOOSH

### Specific Complications (see *General Fracture Complications*, OR7)
- most common: nonunion/malunion (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)
- scaphoid nonunion advanced collapse (SNAC) – chronic nonunion leading to advanced collapse and arthritis of wrist

### Prognosis
- proximal fifth fracture: AVN rate 100%; proximal third fracture: AVN rate 33%
- waist fractures have healing rates of 80-90%
- distal third fractures have healing rates close to 100%

The proximal pole of the scaphoid receives as much as 100% of its arterial blood supply from the radial artery that enters at the distal pole. A fracture through the proximal third disrupts this blood supply and results in a high incidence of AVN/nonunion

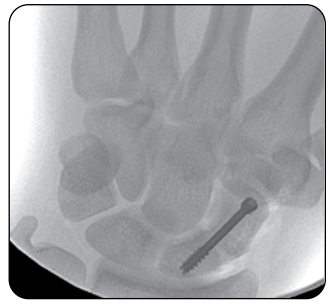

**Figure 24. ORIF left scaphoid**

# Hand

- see Plastic Surgery, PL23

# Spine

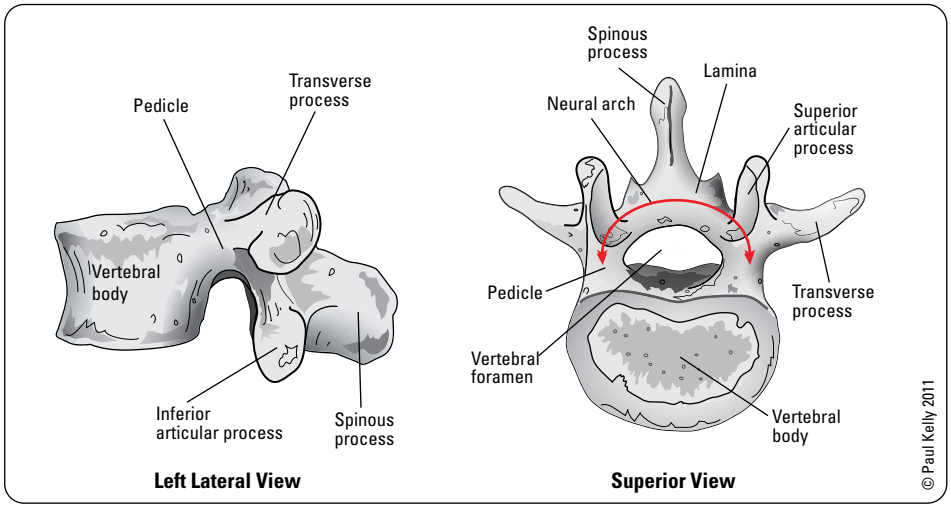

**Figure 27. Schematic diagram of vertebral anatomy**
Adapted from: Moore KL, Agur AMR. Essential Clinical Anatomy, 3rd ed. Philadephia: Lippincott Williams and Wilkins, 2007. p274

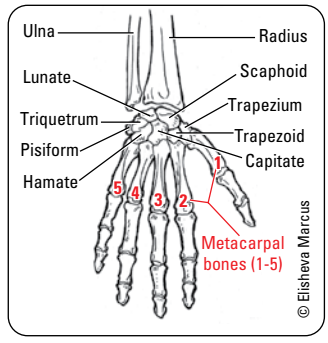

**Figure 25. Carpal bones**

## Fractures of the Spine

- see Neurosurgery, NS34

## Cervical Spine

### General Principles
- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

### Special Testing
- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain

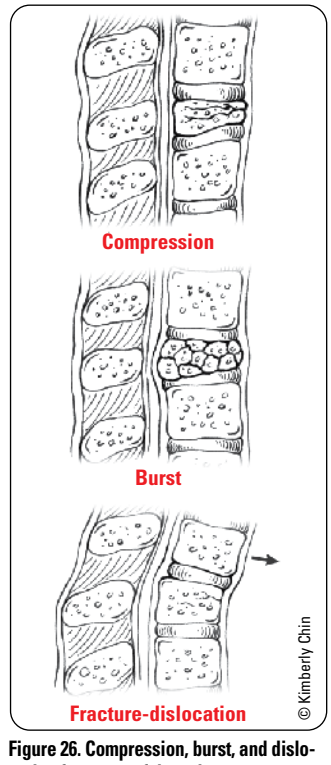

**Figure 26. Compression, burst, and dislocation fractures of the spine**

**Table 14. Cervical Radiculopathy/Neuropathy**

| Root | C5 | C6 | C7 | C8 |
|---|---|---|---|---|
| **Motor** | Deltoid<br>Biceps<br>Wrist extension | Biceps<br>Brachioradialis | Triceps<br>Wrist flexion<br>Finger extension | Interossei<br>Digital flexors |
| **Sensory** | Axillary nerve (patch over lateral deltoid) | Thumb | Index and middle finger | Ring and little finger |
| **Reflex** | Biceps | Biceps<br>Brachioradialis | Triceps | Finger jerk |

### X-Rays for C-Spine
- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
  - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - angulation: between adjacent vertebral bodies (>11° is abnormal)
  - disc or facet joint widening
  - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae

### Differential Diagnosis of C-Spine Pain
- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome, acute discogenic nerve root entrapment, infection, fracture, neoplasm, pain from soft tissue structure

### C-SPINE INJURY
- see Neurosurgery, NS34

## Thoracolumbar Spine

### General Principles
- spinal cord terminates at conus medullaris (L1/2)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

### Special Tests
- **straight leg raise**: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- **Lasegue maneuver**: dorsiflexion of foot during straight leg raise makes symptoms worse, or if leg is less elevated, dorsiflexion will bring on symptoms
- **femoral stretch test**: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in anterior thigh

**Table 15. Lumbar Radiculopathy/Neuropathy**

| Root | L4 | L5 | S1 |
|---|---|---|---|
| **Motor** | Quadriceps (knee extension + hip adduction)<br>Tibialis anterior (ankle inversion + dorsiflexion) | Extensor hallucis longus<br>Gluteus medius (hip abduction) | Peroneus longus + brevis (ankle eversion)<br>Gastrocnemius + soleus (plantar flexion) |
| **Sensory** | Medial malleolus | 1st dorsal webspace and lateral leg | Lateral foot |
| **Screening Test** | Squat and rise | Heel walking | Walking on toes |
| **Reflex** | Knee (patellar) | Medial hamstring* | Ankle (Achilles) |
| **Test** | Femoral stretch | Straight leg raise | Straight leg raise |

*Unreliable

### Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - peripheral nerve compression (disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
   - cauda equina syndrome
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)

## DEGENERATIVE DISC DISEASE

- loss of vertebral disc height with age resulting in:
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation

### Mechanism

- compression over time with age

### Clinical Features

- axial back pain without radicular symptoms
- pain worse with axial loading and flexion
- negative straight leg raise

### Investigations

- X-ray, MRI, provocative discography

### Treatment

- non-operative
  - staying active with modified activity
  - back strengthening
  - NSAIDs
  - **do NOT treat with opioids**; no proven efficacy of spinal traction or manipulation
- operative – rarely indicated
  - decompression ± fusion
  - no difference in outcome between non-operative and surgical management at 2 yr

## SPINAL STENOSIS

- narrowing of spinal canal <10 mm
- congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylosis, Paget's disease, trauma)

### Clinical Features

- ± bilateral back and leg pain
- neurogenic claudication
- ± motor weakness
- normal back flexion; difficulty with back extension (Kemp sign)
- positive straight leg raise, pain not worse with Valsalva

### Investigations

- CT/MRI reveals narrowing of spinal canal, but gold standard = CT myelogram

### Treatment

- non-operative
  - vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
- operative
  - indication: non-operative failure >6 mo
  - decompressive surgery

**Table 16. Differentiating Claudication**

| | Neurogenic | Vascular |
|---|---|---|
| **Aggravation** | With standing or exercise<br>Walking distance variable | Walking set distance |
| **Alleviation** | Change in position (usually flexion, sitting, lying down) | Stop walking |
| **Time** | Relief in ~10 min | Relief in ~2 min |
| **Character** | Neurogenic ± neurological deficit | Muscular cramping |

## MECHANICAL BACK PAIN

- back pain NOT due to prolapsed disc or any other clearly defined pathology

### Clinical Features

- dull backache aggravated by activity and prolonged standing
- morning stiffness
- no neurological signs

### Treatment

- symptomatic (analgesics, physiotherapy)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

Cauda equina syndrome and ruptured aortic aneurysms are causes of low back pain that are considered surgical emergencies

## LUMBAR DISC HERNIATION

- tear in annulus fibrosus allows protrusion of nucleus pulposus, causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- 3:1 male to female
- only 5% become symptomatic
- usually a history of flexion-type injury

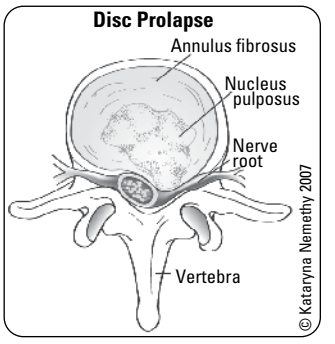

**Figure 28. Disc herniation causing nerve root compression**

### Clinical Features

- back dominant pain (central herniation) or leg dominant pain (lateral herniation)
- tenderness between spinous processes at affected level
- muscle spasm ± loss of normal lumbar lordosis
- neurological disturbance is segmental and varies with level of central herniation
  - motor weakness (L4, L5, S1)
  - diminished reflexes (L4, S1)
  - diminished sensation (L4, L5, S1)
- positive straight leg raise
- positive contralateral SLR
- positive Lasegue and Bowstring sign
- cauda equina syndrome (present in 1-10%): surgical emergency

### Investigations

- X-ray, MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome

Neurogenic claudication is position dependent; vascular claudication is exercise dependent

### Treatment

- non-operative
  - symptomatic
    - extension protocol
    - NSAIDS
- operative
  - indication: progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation
  - surgical discectomy
- prognosis
  - 90% of patients improve in 3 mo with non-operative treatment

MRI abnormalities (e.g. spinal stenosis, disc herniation) are quite common in both asymptomatic and symptomatic individuals and are not necessarily an indication for intervention without clinical correlation

**Table 17. Types of Low Back Pain**

| | Mechanical Back Pain | | Direct Nerve Root Compression | |
|---|---|---|---|---|
| | **Disc Origin** | **Facet Origin** | **Spinal Stenosis** | **Root Compression** |
| **Pain Dominance** | Back | Back | Leg | Leg |
| **Aggravation** | Flexion | Extension, standing, walking | Exercise, extension, walking, standing | Flexion |
| **Onset** | Gradual | More sudden | Congenital or acquired | Acute leg ± back pain |
| **Duration** | Long (weeks, months) | Shorter (days, weeks) | Acute or chronic history (weeks to months) | Short episodes Attacks (minutes) |
| **Treatment** | Relief of strain, exercise | Relief of strain, exercise | Relief of strain, exercise + surgical decompression if progressive or severe deficit | Relief of strain, exercise + surgical decompression if progressive or severe deficit |

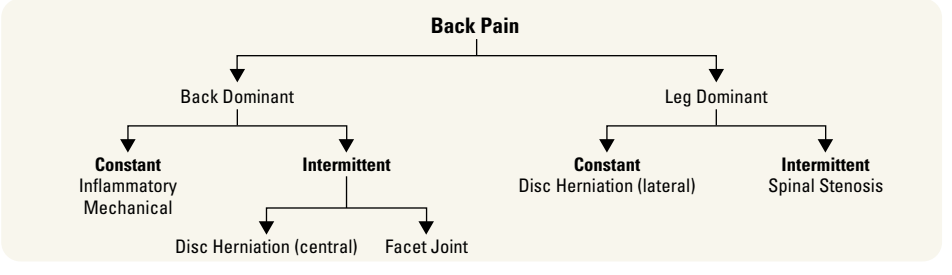

**Figure 29. Approach to back pain**

**Red Flags for**

**BACK PAIN**
**B**owel or bladder dysfunction
**A**nesthesia (saddle)
**C**onstitutional symptoms/malignancy
**K**hronic disease
**P**aresthesias
**A**ge >50 yr
**I**V drug use
**N**euromotor deficits

## SPONDYLOLYSIS

### Definition

- defect in the pars interarticularis with no movement of the vertebral bodies

### Mechanism

- trauma: gymnasts, weightlifters, backpackers, loggers, labourers

**Sciatica**

- Most common symptom of radiculopathy (L4-S3)
- Leg dominant, constant, burning pain
- Pain radiates down leg ± foot
- Most common cause = disc herniation

### Clinical Features
- activity-related back pain, pain with unilateral extension (Michelis' test)

### Investigations
- oblique X-ray: "collar" break in the "Scottie dog's" neck
- bone scan
- CT scan

### Treatment
- non-operative
  - activity restriction, brace, stretching exercise

## ADULT ISTHMIC SPONDYLOLISTHESIS

### Definition
- defect in pars interarticularis causing a forward translation or slippage of one vertebra on another, usually at L5-S1, less commonly at L4-5

### Mechanism
- congenital (children), degenerative (adults), traumatic, pathological, teratogenic

### Clinical Features
- lower back pain radiating to buttocks relieved with sitting
- neurogenic claudication
- L5 radiculopathy
- Meyerding Classification (percentage of slip)

### Investigations
- X-ray (AP, lateral, oblique flexion-extension views), MRI

### Treatment
- non-operative
  - activity restriction, bracing, NSAIDS
- operative

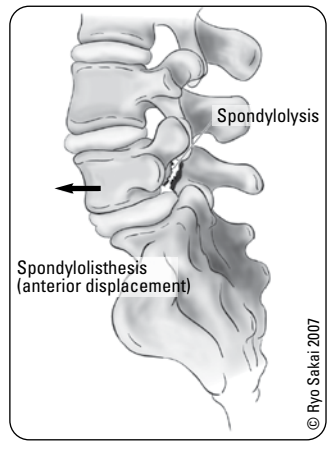

**Figure 30. Spondylolysis, spondylolisthesis**

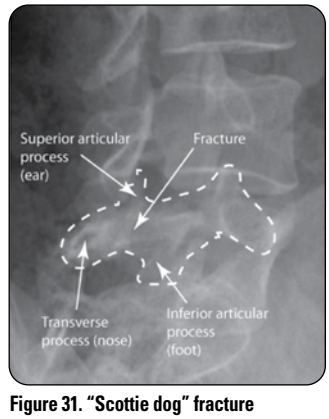

**Figure 31. "Scottie dog" fracture**

**Table 18. Classification and Treatment of Spondylolisthesis**

| Class | Percentage of Slip | Treatment |
|---|---|---|
| 1 | 0-25% | Symptomatic operative fusion only for intractable pain |
| 2 | 25-50 | Same as above |
| 3 | 50-75 | Decompression for spondylolisthesis and spinal fusion |
| 4 | 75-100 | Same as above |
| 5 | >100 | Same as above |

### Specific Complications
- may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

# Pelvis

## Pelvic Fracture

### Mechanism
- young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- elderly: fall from standing height, low energy trauma
- lateral compression, vertical shear, or anteroposterior compression fractures

### Clinical Features
- pain, inability to bear weight
- local swelling, tenderness
- deformity of lower extremity
- pelvic instability

### Investigations
- X-ray: AP pelvis, inlet and outlet views, Judet views (obturator and iliac oblique for acetabular fracture)
  - 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, teardrop, roof, posterior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - if involved, the fracture is considered an open fracture

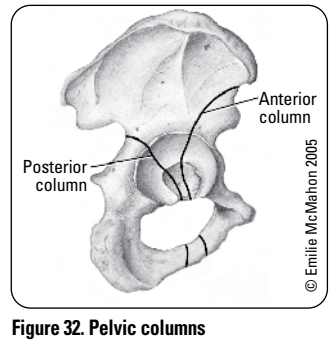

**Figure 32. Pelvic columns**

### Classification

**Table 19. Tile Classification of Pelvic Fractures**

| Type | Stability | Description |
|---|---|---|
| **A** | Rotationally stable<br>Vertically stable | A1: fracture not involving pelvic ring (i.e. avulsion or iliac wing fracture)<br>A2: minimally displaced fracture of pelvic ring (e.g. ramus fracture)<br>A3: transverse sacral fracture |
| **B** | Rotationally unstable<br>Vertically stable | B1: open book (external rotation)<br>B2: lateral compression – ipsilateral<br>B2-1: with anterior ring rotation/displacement through ipsilateral rami<br>B2-2: with anterior ring rotation/displacement through non-ipsilateral rami (bucket-handle)<br>B3: bilateral |
| **C** | Rotationally unstable<br>Vertically unstable | C1: unilateral<br>C1-1: iliac fracture, C1-2: sacroiliac fracture-dislocation<br>C1-3: sacral fracture<br>C2: bilateral with 1 side type B and 1 side type C<br>C3: bilateral both sides type C |

**Possible Radiological Findings**
- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (iliopectineal line) or posterior column (ilioischial line)
- "Teardrop" displacement: acetabular fracture
- Iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)

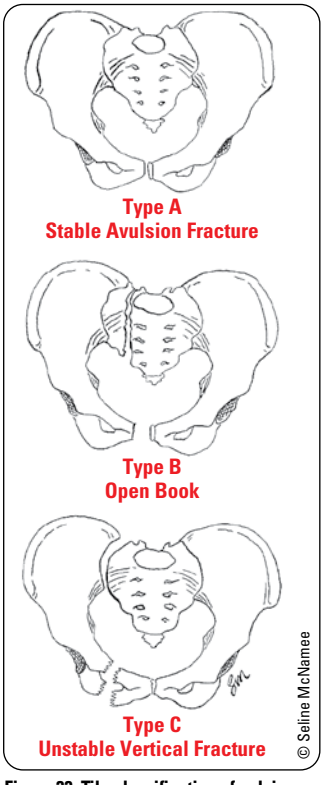

**Figure 33. Tile classification of pelvic fractures**

### Treatment
- ABCDEs
- non-operative treatment: protected weight bearing
  - indication: stable fracture (e.g. elderly patient with fracture sustained in fall from standing)
- emergency management
  - IV fluids/blood
  - pelvic binder/sheeting
  - external fixation vs. emergent angiography/embolization
  - ± laparotomy (if FAST/DPL positive)
- operative treatment: ORIF
  - indications
- unstable pelvic ring injury
- disruption of anterior and posterior SI ligament
- symphysis diastasis >2.5 cm
- vertical instability of the posterior pelvis
- open fracture

### Specific Complications (see *General Fracture Complications*, OR7)
- hemorrhage (**life-threatening**)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

# Hip

## Hip Dislocation

- full trauma survey (see Emergency Medicine, *Patient Assessment/Management*, ER2)
- examine for neurovascular injury prior to open or closed reduction
- reduce hip dislocations within 6 h to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see *Hip Dislocation Post-Total Hip Arthroplasty*, OR30

### ANTERIOR HIP DISLOCATION
- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

### POSTERIOR HIP DISLOCATION
- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
  - e.g. knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb

Up to 50% of patients with hip dislocations suffer fractures elsewhere at the time of injury

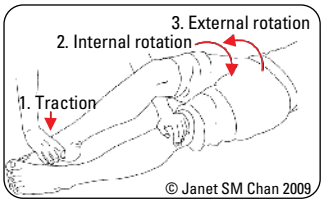

**Figure 34. Rochester method**

- treatment
  - closed reduction under conscious sedation/GA only if no associated femoral neck fracture or ipsilateral displacement
  - ORIF if unstable, intra-articular fragments, or posterior wall fracture
  - post-reduction CT to assess joint congruity and fractures
  - if reduction is unstable, put in traction x 4-6 wk

### COMPLICATIONS FOR ALL HIP DISLOCATIONS

- post-traumatic OA
- AVN of femoral head
- fracture of femoral head, neck, or shaft
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism – DVT/PE

## Hip Fracture

### General Features

- acute onset of hip pain
- unable to weight-bear
- shortened and externally-rotated leg
- painful ROM

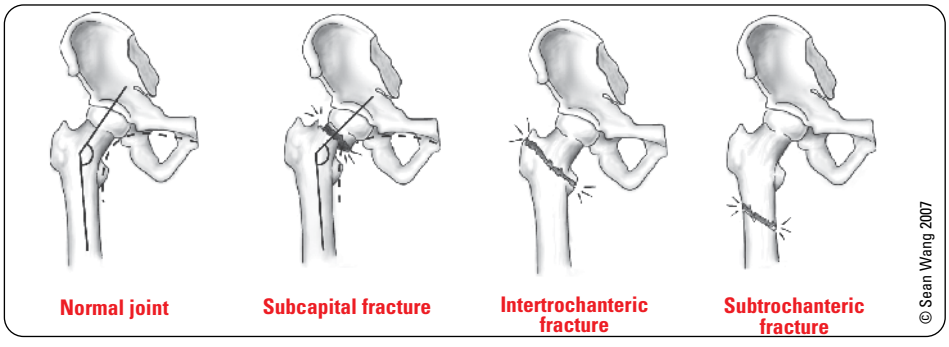

**Figure 35. Subcapital, intertrochanteric, and subtrochanteric hip fractures**

**Table 20. Overview of Hip Fractures**

| Fracture Type | Definition | Mechanism | Special Clinical Features | Investigations | Treatment | Complications |
|---|---|---|---|---|---|---|
| **Femoral Neck (Subcapital)** | Intracapsular (See *Garden Classification*, Table 21) | Young: MVC, fall from height<br>Elderly: fall from standing, rotational force | Same as general | X-Ray: AP hip, AP pelvis, cross table lateral hip | See Table 21 | DVT, non-union, AVN, dislocation |
| **Intertrochanteric**<br>Stable: intact posteromedial cortex<br>Unstable: non-intact posteromedial cortex | Extracapsular fracture including the greater and lesser trochanters and transitional bone between the neck and shaft | Same as femoral neck fracture<br>Direct or indirect force transmitted to the intertrochanteric area | Ecchymosis at back of upper thigh | X-Ray: AP pelvis, AP/lateral hip | Closed reduction under fluoroscopy then dynamic hip screw or IM nail | DVT, varus displacement of proximal fragment, malrotation, non-union, failure of fixation device |
| **Subtrochanteric** | Fracture begins at or below the lesser trochanter and involves the proximal femoral shaft | Young: high energy trauma<br>Elderly: osteopenic bone + fall, pathological fracture | Ecchymosis at back of upper thigh | X-Ray: AP pelvis, AP/lateral hip and femur | Closed/open under fluoroscopy, then plate fixation or IM nail | Malalignment, non-union, wound infection |

**X-Ray Features of Subcapital Hip Fractures**
- Disruption of Shenton's line (a radiographic line drawn along the upper margin of the obturator foramen, extending along the inferomedial side of the femoral neck)
- Altered neck-shaft angle (normal is 120-130°)

**DVT Prophylaxis in Hip Fractures**
LMWH (i.e. enoxaparin 40 mg SC bid), fondaparinux, low dose heparin on admission, do not give <12 h before surgery

**AVN of Femoral Head**
- Distal to proximal blood supply along femoral neck to head (medial and lateral femoral circumflex arteries)
- Susceptible to AVN if blood supply disrupted
- Etiology: femoral neck fracture, chronic systemic steroid use, SCFE, Legg-Calvé-Perthes, SLE, RA

**Comparative Effectiveness of Pain Management Interventions for Hip Fracture: A Systematic Review**
**Study**: Randomized controlled trials (RCTs); nonrandomized controlled trials (non-RCTs); and cohort studies of pain management techniques in older adults after acute hip fracture.
**Conclusions**: Nerve blockade seems to be effective in reducing acute pain after hip fracture. Low-level evidence suggests that preoperative traction does not reduce acute pain. Evidence was insufficient on the benefits and harms of many other interventions.

**Table 21. Garden Classification of Femoral Neck Fractures**

| Type | Displacement | Extent | Alignment | Trabeculae | Treatment |
|---|---|---|---|---|---|
| I | None | "Incomplete" | Valgus or neutral | Malaligned | Internal fixation to prevent displacement (valgus impacted fracture) |
| II | None | Complete | Neutral | Aligned | Internal fixation to prevent displacement |
| III | Some | Complete | Varus | Malaligned | Young: ORIF<br>Elderly: hemi-/total hip arthroplasty |
| IV | Complete | Complete | Varus | Aligned | Young: ORIF<br>Elderly: hemi-/total hip arthroplasty |

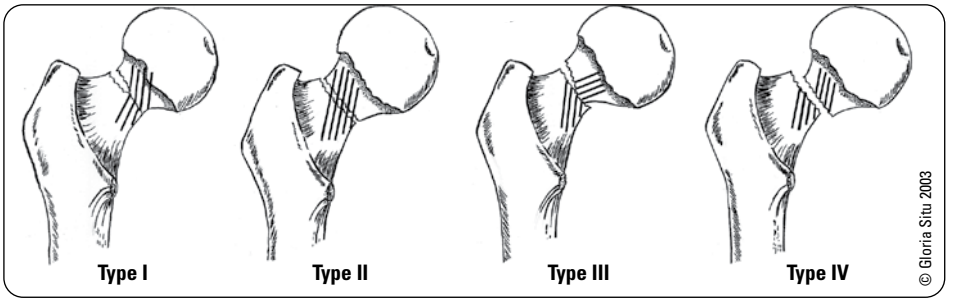

**Figure 36. Garden classification of femoral neck fractures**

# Arthritis of the Hip

### Etiology
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

### Clinical Features
- pain (groin, medial thigh) and stiffness aggravated by activity, better with rest in OA
- RA: morning stiffness >1 h, multiple joint swelling, hand nodules
- decreased ROM (internal rotation is lost first)
- crepitus
- effusion
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenburg sign

### Investigations
- X-ray: weight-bearing views of affected joint
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - RA: osteopenia, erosion, joint space narrowing, subchondral cysts
- blood work: ANA, RF

### Treatment
- non-operative
  - weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative
  - indication: advanced disease
  - realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
- complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
- arthroplasty is standard of care in most patients with hip arthritis

# Hip Dislocation Post-Total Hip Arthroplasty

- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

### Mechanism
- THA that is unstable when hip is flexed, adducted, and internally rotated, or extended and externally rotated

### Investigations
- X-ray: AP pelvis, AP and lateral views of the hip

### Treatment
- non-operative
  - closed reduction
- operative
  - indication: 2 or more dislocations with evidence of polyethylene wear, malalignment, hardware failure
  - revision THA
  - infected hip (infection can cause hip instability)
  - conversion to hemiarthroplasty with a larger femoral head
  - resection arthroplasty is a last resort

**DVT Prophylaxis in Elective THA**
(continue 10-35 d post-operative)
DOACs (e.g. rivaroxaban), ASA, fondaparinux, low molecular weight heparin, or warfarin

### Complications
- sciatic nerve palsy in 25% (10% permanent)
- HO
- infection

# Femur

## Femoral Diaphysis Fracture

### Mechanism
- high energy trauma (MVC, fall from height, gunshot wound)
  - pathologic as a result of malignancy, osteoporosis, bisphosphonate use
- in children, can result from low energy trauma (spiral fracture)
  - always consider the possibility of non-accidental trauma

### Clinical Features
- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (Table 6)
- Winquist and Hansen classification

It is important to rule out ipsilateral femoral neck fracture, as they occur in 2-6% of femoral diaphysis fractures and are reportedly missed in 19-31% of cases

### Investigations
- X-ray: AP pelvis, AP, and lateral views of the hip, femur, knee

### Treatment
- non-operative (uncommon)
  - indication: non-displaced femoral shaft fractures in co-morbid patients
  - long leg cast
- operative
  - ORIF with anterograde IM nail (most common) or retrograde IM nail
  - external fixator for unstable patients or polytrauma with open fractures
  - early mobilization and strengthening

### Complications
- blood loss
- fat embolism leading to ARDS
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture (2-6%)
- nerve injury

## Distal Femoral Fracture

- fractures from articular surface to 5 cm above metaphyseal flare

### Mechanism
- direct high energy force or axial loading
- three types: extra articular, partial articular, complete articular

### Clinical Features
- extreme pain
- knee effusion (hemarthrosis)
- neurovascular deficits can occur with displaced fracture

### Investigations
- X-ray: AP and lateral views
- CT, angiography if diminished pulses

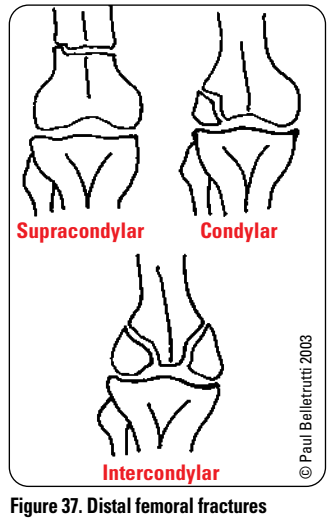

**Figure 37. Distal femoral fractures**

### Treatment
- non-operative (uncommon)
  - indication: non-displaced extra-articular fracture, poor surgical candidate
- hinged knee brace
- operative
  - indication: displaced fracture, intra-articular fracture, non-union
- ORIF or retrograde IM nail if supracondylar and non-comminuted
- early mobilization and strengthening

### Specific Complications (see *General Fracture Complications*, OR7)
- femoral artery tear
- popliteal artery injury
- nerve injury
- extensive soft tissue injury
- angulation deformities

# Knee

## Evaluation of Knee

### Common Complaints
- locking, instability, and swelling
  - torn meniscus/loose body in joint
- pseudo-locking: limited ROM without mechanical block
  - effusion, muscle spasm after injury, arthritis
- painful, audible clicking
  - torn meniscus
- giving way: instability
  - cruciate ligament or meniscal tear, patellar dislocation

### Special Tests of the Knee
- **anterior and posterior drawer tests (Figure 40)**
  - demonstrates torn ACL and PCL, respectively
  - knee flexed at 90°, foot immobilized, hamstrings released
  - if able to sublux tibia anteriorly (anterior drawer test), then ACL may be torn
  - if able to sublux tibia posteriorly (posterior drawer test), then PCL may be torn
  - anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio
- **Lachman test**
  - demonstrates torn ACL
  - hold knee in 10-20° flexion, stabilizing the femur
  - try to sublux tibia anteriorly on femur
  - similar to anterior drawer test, more reliable due to less muscular stabilization
  - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio
- **pivot shift sign**
  - demonstrates torn ACL
  - start with the knee in extension
  - internally rotate foot, slowly flex knee while palpating and applying a valgus force
  - if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the "pivot")
  - reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
  - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio
- **posterior sag sign**
  - demonstrates torn PCL
  - may give a false positive anterior draw sign
  - flex knees and hips to 90°, hold ankles and knees
  - view from the lateral aspect
  - if one tibia sags posteriorly compared to the other, its PCL is torn
- **collateral ligament stress test**
  - palpate ligament for "opening" of joint space while testing
  - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  - repeat tests with knee in 20° flexion to relax joint capsule
  - opening in 20° flexion due to MCL damage only
  - opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage
- **tests for meniscal tear**
  - **joint line tenderness**
    - joint line pain when palpated
    - palpate one side at a time and watch patient's eyes
    - for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio

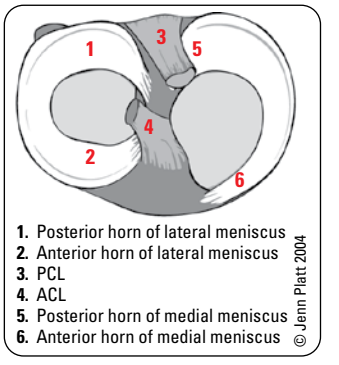

**Figure 38. Diagram of the right tibial plateau**

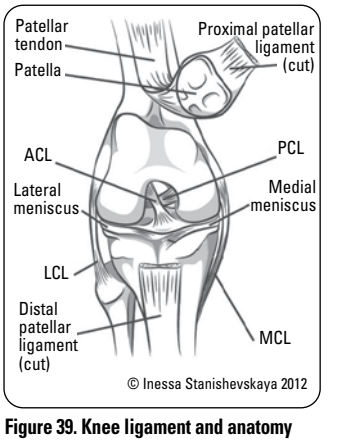

**Figure 39. Knee ligament and anatomy**

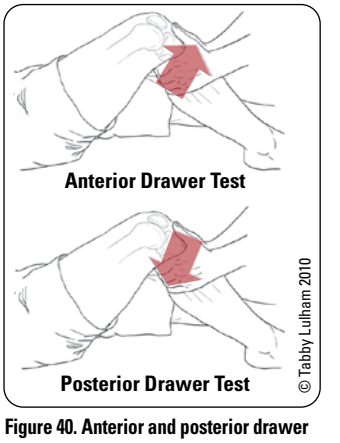

**Figure 40. Anterior and posterior drawer test**

**6 Degrees of Freedom of the Knee**
- Flexion and extension
- External and internal rotation
- Varus and valgus angulation
- Anterior and posterior glide
- Medial and lateral shift
- Compression and distraction

On physical exam of the knee, do not forget to evaluate the hip

- **crouch compression test**
  - joint line pain when squatting (anterior pain suggests patellofemoral pathology)
- **McMurray's test**
  - with knee in flexion, palpate joint line for painful pop or click
  - lateral meniscus tear exam: internally rotate foot, varus stress, and extend knee
  - medial meniscus tear exam: externally rotate foot, valgus stress, and extend knee
  - for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
- **Thessaly test**
  - patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion
  - positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort
  - for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
  - for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio
  - composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

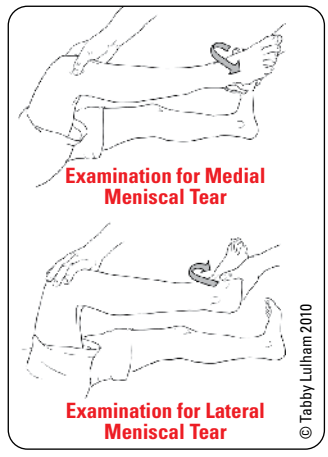

**Figure 41. McMurray test**

### X-Rays
- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see Emergency Medicine, ER16)

## Cruciate Ligament Tears

- ACL tear much more common than PCL tear

**Table 22. Comparison of ACL and PCL Injuries**

| | Anterior Cruciate Ligament | Posterior Cruciate Ligament |
|---|---|---|
| **Anatomy** | From medial wall of lateral femoral condyle to the anteromedial and posterolateral intercondyloid eminence of the tibial plateau | Lateral wall of medial femoral condyle to posterior intercondyloid eminence of the tibial plateau |
| **Mechanism** | Sudden deceleration<br>Hyperextension and internal rotation of tibia on femur (i.e. "plant and turn") | Sudden posterior displacement of tibia when knee is flexed or hyperextended (e.g. dashboard MVC injury) |
| **History** | Audible "pop"<br>Immediate swelling<br>Knee "giving way"<br>Inability to continue activity | Audible "pop"<br>Immediate swelling<br>Pain with push off<br>Cannot descend stairs |
| **Physical** | Effusion (hemarthrosis)<br>Posterolateral joint line tenderness<br>Positive anterior drawer<br>Positive Lachmann<br>Pivot shift<br>Test for MCL, meniscal injuries | Effusion (hemarthrosis)<br>Anteromedial joint line tenderness<br>Positive posterior drawer<br>Reverse pivot shift<br>Other ligamentous, bony injuries |
| **Treatment** | Stable knee with minimal functional impairment: immobilization 2-4 wk with early ROM and strengthening<br>High demand lifestyle: ligament reconstruction | Unstable knee or young person/high-demand lifestyle: ligament reconstruction |

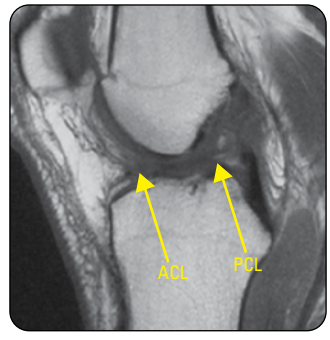

**Figure 42. T1 MRI of torn ACL and PCL**

## Collateral Ligament Tears

### Mechanism
- valgus force to knee = MCL tear
- varus force to knee = LCL tear

### Clinical Features
- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus or valgus force to knee
  - laxity with endpoint suggests partial tear
  - laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O'Donoghue's unhappy triad), common peroneal nerve injury

**O'Donoghue's Unhappy Triad**
- ACL rupture
- MCL rupture
- Meniscal damage (medial and/or lateral)

### Investigations
- X-ray: AP and lateral views of the knee; MRI

### Treatment
- non-operative
  - partial tear: immobilization x 2-4 wk with early ROM and strengthening
  - complete tear: immobilization at 30° flexion
- operative
  - indication: multiple ligamentous injuries
  - surgical repair of ligaments

Partial ligamentous tears are much more painful than complete ligamentous tears

## Meniscal Tears

- medial tear much more common than lateral tear

### Mechanism
- twisting force on knee when it is partially flexed (e.g. stepping down and turning)
- requires moderate trauma in young person, but only mild trauma in elderly due to degeneration

### Clinical Features
- immediate pain, difficulty weight-bearing, instability, and clicking
- increased pain with squatting and/or twisting
- effusion (hemarthrosis) with insidious onset (24-48 h after injury)
- joint line tenderness medially or laterally
- locking of knee (if portion of meniscus mechanically obstructing extension)

### Investigations
- MRI, arthroscopy

### Treatment
- non-operative
  - indication: not locked
  - ROM and strengthening (NSAIDs)
- operative
  - indication: locked (i.e. patient cannot fully extend knee, due to mechanical block) or failed non-operative treatment
  - arthroscopic repair/partial meniscectomy

Meniscal repair is done if tear is peripheral with good vascular supply, is a longitudinal tear and 1-4 cm in length
Partial meniscectomy is done with tears not amenable to repair (complex, degenerative, radial)

**Tissue Sources for ACL Reconstruction**
- Hamstring
- Middle 1/3 patellar tendon (bone-patellar-bone)
- Allograft (e.g. cadaver)

## Popliteal Cysts

- synovial fluid-filled mass located in the popliteal fossa (i.e. Baker's cyst)

### Etiology
- classified as primary (distension of the bursa with no communication to joint) or secondary (communication between bursa and joint, bursa fills with articular fluid)
- primary cysts are usually congenital in children, while secondary are acquired from traumatic injury or degenerative/inflammatory joint disease in adults

### Clinical Features
- usually asymptomatic bulge on the posterior aspect of the knee
- usually located between the semimembranosus and medial head of gastrocnemius
- may cause local tightness, restricted range of motion or posterior knee pain
- symptoms may worsen with physical activity
- for secondary popliteal cysts, symptoms are more associated with the underlying condition of the knee

### Investigations
- clinical diagnosis is often sufficient
- ultrasonography can be used to identify cyst and its relation to adjacent soft tissue structures
- knee X-ray to assess for joint abnormalities that may be associated with the cyst
- MRI allows for clearest visualization but this is only indicated to plan for surgery, when an underlying knee pathology such as a meniscal tear is suspected, or when the diagnosis is uncertain after ultrasonography

### Treatment
- asymptomatic cysts do not require treatment
- non-operative
  - indication: initial treatment for symptomatic secondary popliteal cysts
  - identify and treat underlying cause
  - rest, NSAIDs, cold packs for symptomatic treatment
  - aspiration and intra-articular steroid injection may offer temporary relief
- operative
  - indication: primary symptomatic popliteal cyst, resistant to initial treatment, absence of identifiable joint pathology
  - surgical excision using a posterior approach

# Quadriceps/Patellar Tendon Rupture

### Mechanism
- sudden forceful contraction of quadriceps during an attempt to stop
- more common in obese patients and those with pre-existing degenerative changes in tendon
  - DM, SLE, RA, steroid use, renal failure on dialysis

### Clinical Features
- inability to extend knee or weight-bear
- possible audible "pop"
- patella in lower or higher position with palpable gap above or below patella, respectively
- may have an effusion

Patella alta = high riding patella
Patella baja (infera) = low riding patella

### Investigations
- ask patient to perform straight leg raise (unable to with complete rupture)
- knee X-ray to rule out patellar fracture, MRI to distinguish between complete and partial tears
- lateral view: patella alta with patella tendon rupture, patella baja (infera) with quadriceps tendon rupture

### Treatment
- non-operative
  - indication: incomplete tears with preserved extension of knee
  - immobilization in brace
- operative
  - indication: complete ruptures with loss of extensor mechanism
- early surgical repair: better outcomes compared with delayed repair (>6 wk post-injury)
- delayed repair complicated by quadriceps contracture, patella migration, and adhesions

# Dislocated Knee

### Mechanism
- high energy trauma
- by definition, caused by tears of multiple ligaments

### Clinical Features
- classified by relation of tibia with respect to femur
  - anterior, posterior, lateral, medial, rotary
- knee instability
- effusion
- pain
- ischemic limb
- Schenck classification

**Schenck Classification**
Type 1: Single ligament injury (ACL or PCL)
Type 2: Injury to ACL and PCL
Type 3: Injury to ACL, PCL and either MCL or LCL
Type 4: Injury to ACL, PCL, MCL, LCL
Type 5: Multiligamentous injury with periarticular fracture

### Investigations
- X-ray: AP, lateral, and skyline views of the knee
  - associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
- Assessment of NVS:
  - ABI (abnormal if <0.9)
  - arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)
  - assessment of peroneal nerve, tibial artery, and ligamentous injuries

### Treatment
- urgent closed reduction
  - complicated by interposed soft tissue
- assessment of peroneal nerve, tibial artery, and ligamentous injuries
- emergent operative repair if vascular injury, open fracture or dislocation, irreducible dislocation, compartment syndrome
- knee immobilization x 6-8 wk

### Specific Complications
- high incidence of associated injuries
- popliteal artery tear
- peroneal nerve injury
- capsular tear
- chronic: instability, stiffness, post-traumatic arthritis

# Patella

## Patellar Fracture

### Mechanism
- direct blow to the patella: fall, MVC (dashboard)
- indirect trauma by sudden flexion of knee against contracted quadriceps

### Clinical Features
- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- ± effusion/hemarthrosis

### Investigations
- X-rays: AP, lateral, skyline
- do not confuse with bipartite patella: congenitally unfused ossification centres with smooth margins on X-ray at superolateral corner

### Treatment
- non-operative
  - indication: non-displaced (step-off <2-3 mm and fracture gap <1-4 mm)
- straight leg immobilization 1-4 wk with hinged knee brace, weight bearing as tolerated
- progress in flexion after 2-3 wk
- physiotherapy: quadriceps strengthening when pain has subsided
- operative
  - indication: displaced (>2 mm), comminuted, disrupted extensor mechanism
  - ORIF, if comminuted may require partial/complete patellectomy
- goal: restore extensor mechanism with maximal articular congruency

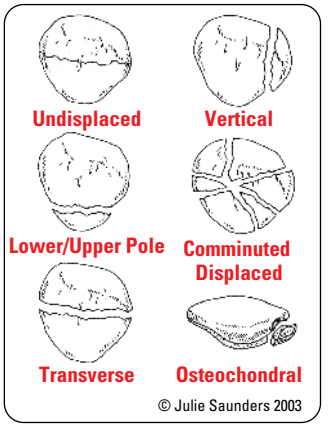

**Figure 43. Types of patellar fractures**

**Complications**
- Symptomatic wiring
- Loss of reduction
- Osteonecrosis (proximal fragment)
- Hardware failure
- Knee stiffness
- Nonunion
- Infection

## Patellar Dislocation

### Mechanism
- usually a non-contact twisting injury
- lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
- direct blow e.g. knee/helmet to knee collision

### Risk Factors
- young, female
- obesity
- high-riding patella (patella alta)
- genu valgus
- Q-angle (quadriceps angle) ≥20°
- shallow intercondylar groove
- weak vastus medialis
- tight lateral retinaculum
- ligamentous laxity (Ehlers-Danlos)

### Clinical Features
- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- positive patellar apprehension test
  - passive lateral translation results in guarding and patient apprehension
- often recurrent, self-reducing
- concomitant MCL injury
- increased Q-angle
- J-sign

### Investigations
- X-rays: AP, lateral, and skyline views of the knee
- check for fracture of medial patella (most common) and lateral femoral condyle

### Treatment
- non-operative first
  - NSAIDs, activity modification, and physical therapy
  - short-term immobilization for comfort, then 6 wk controlled motion
  - progressive weight bearing and isometric quadriceps strengthening
- operative
  - indication: if recurrent or if loose bodies present
  - surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

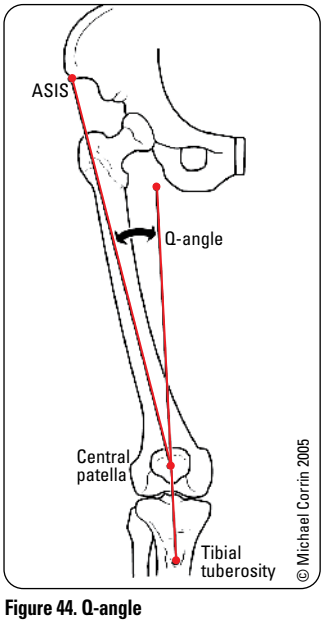

**Figure 44. Q-angle**
The angle between a vertical line through the patella and tibial tuberosity and a line from the ASIS to the middle patella; the larger the angle, the greater the amount of lateral force on the knee (normal <20°)

**J-sign:** Associated with patella alta; increased lateral translation in extension which pops into the patellofemoal groove as the patella engages the trochlea early in flexion

## Patellofemoral Syndrome (Chondromalacia Patellae)

- syndrome of anterior knee pain associated with idiopathic articular changes of patella

### Risk Factors
- malalignment causing patellar maltracking (Q angle ≥20°, genu valgus)
- post-trauma
- deformity of patella or femoral groove
- recurrent patellar dislocation, ligamentous laxity
- excessive knee strain (athletes)

### Mechanism
- softening, erosion, and fragmentation of articular cartilage, predominantly medial aspect of patella
- commonly seen in active young females

### Clinical Features
- deep, aching anterior knee pain
  - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting, or kneeling
- insidious onset and vague in nature
- sensation of instability, pseudolocking
- pain with extension against resistance through terminal 30-40°
- pain with compression of patella with knee ROM or resisted knee extension
- swelling rare, minimal if present
- palpable crepitus

Pain with firm compression of patella into medial femoral groove is pathognomonic of patellofemoral syndrome

### Investigations
- X-ray: AP, lateral, and skyline views of the knee – may find chondrosis, lateral patellar tilt, patella alta/baja, or shallow sulcus
- CT-scan
- MRI – best to assess articular cartilage

### Treatment
- non-operative
  - continue non-impact activities; rest and rehabilitation
  - NSAIDs
  - physiotherapy: vastus medialis and core strengthening
- operative
  - indication: failed non-operative treatment
  - tibial tubercle elevation
  - arthroscopic shaving/debridement
  - lateral release of retinaculum

# Tibia

## Tibial Plateau Fracture

### Mechanism
- varus/valgus load ± axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in those with osteoporosis

### Clinical Features
- frequency: lateral > bicondylar > medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion
- inability to bear weight
- swelling
- risk of compartment syndrome, ACL injury, meniscal tears and vascular injuries
- Schatzker classification

**Schatzker Classification**

| Type | Description |
|---|---|
| I | Involvement of lateral plateau split fracture |
| II | Lateral split-depressed fracture |
| III | Involvement of lateral plateau: pure depression fracture |
| IV | Medial plateau fracture |
| V | Bicondylar plateau fracture |
| VI | Bicondylar with metaphyseal/diaphyseal involvement |

### Investigations
- X-ray: AP, lateral, and oblique views
- CT: pre-operative planning, identify articular depression and comminution
- ABI if any differences in pulses between extremities

### Treatment

| | |
|---|---|
| **Approach #1 (based on amount of depression seen on x-ray)** | **Non-operative indication** (if depression on x-ray is <3 mm): hinged knee brace, PWB 8-12 wk, immediate passive ROM<br>**Operative indication** (if depression is >3 mm, all medial plateau or bicondylar fractures): ORIF often requiring bone grafting to elevate depressed fragment |
| **Approach #2 (based on varus/valgus instability)** | **Non-operative indication** (if minimal varus/valgus instability [<15°]): straight leg immobilization x 4-6 wk with progressive ROM weight bearing<br>**Operative indication** (if significant varus/valgus instability [>15°]): ORIF often requiring bone grafting to elevate depressed fragment |

### Specific Complications (see *General Fracture Complications*, OR7)
- ligamentous injuries
- meniscal lesions
- AVN
- infection
- OA

## Tibial Shaft Fracture

- most common long bone fracture and open fracture

### Mechanism
- low energy pattern: torsional injury
- high energy: including MVC, falls, sporting injuries

### Clinical Features
- pain, inability to weight bear
- open vs. closed
- neurovascular compromise

### Investigations
- X-ray: AP and lateral views
  - full length, plus knee and ankle

### Treatment
- non-operative
  - indication: closed and minimally displaced or adequate closed reduction
- long leg cast x 8-12 wk, functional brace after
- operative
  - indication: displaced or open
- if displaced and closed: ORIF with IM nail, plate and screws, or external fixator
- if open: antibiotics, I&D, external fixation or IM nail, and vascularized coverage of soft tissue defects

### Specific Complications (see *General Fracture Complications*, OR7)
- high incidence of neurovascular injury and compartment syndrome
- poor soft tissue coverage (critical to outcome)

**Figure 45. Tibial shaft fracture treated with IM nail and screws**

Tibial shaft fractures have high incidence of compartment syndrome and are often associated with soft tissue injuries

**Danis-Weber Classification**
- Based on level of fibular fracture relative to syndesmosis

**Type A (infra-syndesmotic)**
- Pure inversion injury, tibiofibular syndesmosis remains intact
- Avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
- ± shear fracture of medial malleolus

**Type B (trans-syndesmotic)**
- External rotation and eversion (most common)
- ± avulsion of medial malleolus or rupture of deltoid ligament
- Spiral fracture of lateral malleolus starting at plafond

**Type C (supra-syndesmotic)**
- Pure external rotation
- Avulsion of medial malleolus or torn deltoid ligament
- ± posterior malleolus avulsion with posterior tibio-fibular ligament
- Fibular fracture is above plafond
- frequently tears syndesmosis

**Ottawa Ankle Rules** (see Emergency Medicine, ER17)

X-rays are only required if:

Pain in the malleolar zone AND bony tenderness over the distal 6 cm of the posterior aspect of the tibia or tip of the medial or lateral malleolus OR inability to weight bear both immediately after injury and in the ER

# Ankle

## Evaluation of Ankle and Foot Complaints

### Special Tests
- anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
- talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by X-ray

### X-Ray
- AP and lateral views
- mortise view: ankle at 15° of internal rotation
  - gives true view of ankle joint
  - joint space should be symmetric with no talar tilt
- Ottawa Ankle Rules should guide X-ray use (see Emergency Medicine, ER17); nearly 100% sensitivity
- ± CT to better characterize fractures

# Ankle Fracture

### Mechanism
- pattern of fracture depends on the position of the ankle when trauma occurs
- generally involves
  - ipsilateral ligamentous tears or transverse bony avulsion
  - contralateral shear fractures (oblique or spiral)
- classification systems
  - Danis-Weber
  - Lauge-Hansen: based on foot's position and motion relative to leg

### Treatment
- non-operative
  - indication: non-displaced, no history of dislocation
  - below knee cast, NWB, or aircast WBAT
- operative
  - indications
    - any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
    - most of type B, and all of type C
    - trimalleolar (medial, posterior, lateral) fractures
    - talar tilt >10°
    - medial clear space on X-ray greater than superior clear space
    - open fracture/open joint injury
  - ORIF

### Complications
- high incidence of post-traumatic arthritis
- high risk of poor wound healing and deep infections (up to 20%) for patients with DM

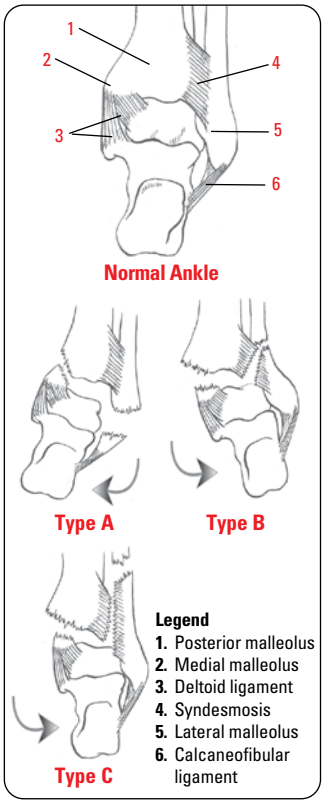

**Figure 46. Ring principle of the ankle and Danis-Weber classification**

# Ankle Ligamentous Injuries

- see Figure 47 for ankle ligaments

### Medial Ligament Complex (deltoid ligament)
- eversion injury
- usually avulses medial or posterior malleolus and strains syndesmosis

### Lateral Ligament Complex (anterior talofibular, calcaneofibular, posterior talofibular)
- inversion injury, >90% of all ankle sprains
- ATF most commonly and severely injured if ankle is plantarflexed
- swelling and tenderness anterior to lateral malleolus
- ++ ecchymosis
- positive ankle anterior drawer
- may have significant medial talar tilt on inversion stress X-ray

### Treatment
- non-operative
  - microscopic tear (Grade I)
    - rest, ice, compression, elevation
  - macroscopic tear (Grade II)
    - strap ankle in dorsiflexion and eversion x 4-6 wk
    - physiotherapy: strengthening and proprioceptive retraining
  - complete tear (Grade III)
    - below knee walking cast x 4-6 wk
    - physiotherapy: strengthening and proprioceptive retraining
    - surgical intervention may be required if chronic symptomatic instability develops

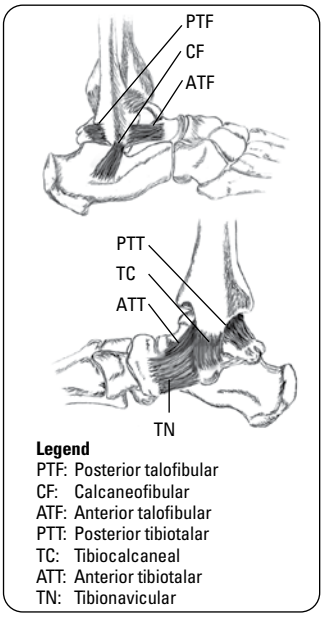

**Figure 47. Ankle ligament complexes**

With a history of significant trauma from axial loading of lower limb, always consider spinal injuries, femoral neck, tibial plateau, and talar/calcaneal fractures

# Foot

## Talar Fracture

### Mechanism
- axial loading or hyperdorsiflexion commonly from MVC or fall from height
- 60% of talus covered by articular cartilage
- talar neck is most common fracture of talus (50%)
- tenuous blood supply runs distal to proximal along talar neck
  - high risk of AVN with displaced fractures

### Investigations
- X-ray: AP, lateral, and Canale views (maximum equinus, 15 degrees pronated) of the foot
- CT to better characterize fracture
- MRI can clearly define extent of AVN

### Treatment
- non-operative
  - indication: non-displaced
  - NWB, below-knee cast x 6 wk
- operative
  - indication: displaced
  - ORIF (high rate of nonunion, AVN)
  - neck fracture: ORIF

## Calcaneal Fracture

- most common tarsal fracture

### Mechanism
- high energy, axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% are intra-articular and 10% are bilateral

**Calcaneal Fracture Treatment Principles**
- Avoid wound complications (10-25%)
- Restore articular congruity
- Restore normal calcaneal width and height
- Maximum functional recovery may take longer than 12 mo

### Clinical Features
- marked swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

### Investigations
- X-rays: AP, lateral, and oblique foot (mandatory views); can also assess with Broden view, Harris view, or AP ankle
- loss of Bohler's angle
- CT: gold-standard, assess intra-articular extension

### Treatment
- closed vs. open reduction is controversial
- NWB cast x 3 mo with early ROM and strengthening

## Achilles Tendonitis

### Mechanism
- chronic inflammation from activity or poor-fitting footwear
- may also develop heel bumps (i.e. retrocalcaneobursitis or Haglund deformity)

**Haglund Deformity**: an enlargement of the posterior-superior tuberosity of the calcaneus

### Clinical Features
- pain, stiffness, and crepitus with ROM
- thickened tendon, palpable bump

### Investigations
- X-ray: lateral, evaluate bone spur and calcification; U/S, MRI (to assess degenerative change)

### Treatment
- non-operative
  - rest, NSAIDs, shoe wear modification (orthotics, open back shoes)
  - heel sleeves and pads are mainstay of non-operative treatment
  - gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
  - shockwave therapy in chronic tendonitis
  - do not inject steroids (risk of tendon rupture)

# Achilles Tendon Rupture

### Mechanism
- loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
- secondary to chronic tendonitis, steroid injection

### Clinical Features
- audible pop, sudden pain with push-off movement
- pain or inability to plantarflex
- palpable gap
- apprehensive toe off when walking
- weak plantarflexion strength
- Thompson test: with patient prone, squeeze calf, normal response is plantar flexion
  - no passive plantarflexion is positive test = ruptured tendon

### Investigations
- X-ray (to rule out other pathology), U/S or MRI (for partial vs. complete ruptures)

### Treatment
- non-operative
  - indication: low athletic demand (new level 1 evidence suggests no difference in re-rupture rates between operative and non-operative management with functional rehabilitation)
  - initial cast foot in plantar flexion (to relax tendon), with functional rehabilitation x 8-12 wk
- operative
  - indication: high athletic demand
  - surgical repair, followed by functional rehabilitation x 8-12 wk

The most common site of Achilles tendon rupture is 2-6 cm from its insertion where the blood supply is the poorest

**Complications of Achilles Tendon Rupture**
- Infection
- Sural nerve injury
- Re-rupture: surgical repair decreases likelihood of re-rupture compared to non-operative management

# Plantar Fasciitis (Heel Spur Syndrome)

### Definition
- inflammation of plantar aponeurosis at calcaneal origin
- common in athletes (especially runners, dancers)
- also associated with obesity, DM, seronegative and seropositive arthritis

### Mechanism
- repetitive strain injury causing microtears and inflammation of plantar fascia

### Clinical Features
- insidious onset of heel pain, pain when getting out of bed, and stiffness
- intense pain when walking from rest that subsides as patient continues to walk, worse at end of day with prolonged standing
- swelling, tenderness over sole
- greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
- pain with toe dorsiflexion (stretches fascia)

### Investigations
- plain radiographs to rule out fractures
- often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
- spur is secondary to inflammation, not the cause of pain

### Treatment
- non-operative
  - pain control and stretching programs are first-line
  - rest, ice, NSAIDs, steroid injection
  - physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
  - orthotics with heel cup – to counteract pronation and disperse heel strike forces
- operative
  - very rarely indicated
  - when performed, includes endoscopic release of fascia

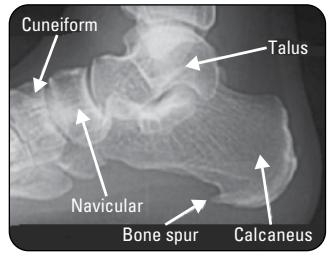

**Figure 48. X-ray of bony heel spur**

**Surgical vs. Nonsurgical Methods for Acute Achilles Tendon Rupture: A Meta-Analysis of Randomized Controlled Trials**
J Foot Ankle Surg Am. 2018 Nov - Dec; 57(6): 1191-1199
**Purpose**: To compare surgical treatment and conservative treatment of acute Achilles tendon rupture.
**Methods**: A meta-analysis was performed looking at randomized trials comparing surgical with nonsurgical treatment or comparing different surgical treatments of Achilles tendon rupture.
**Results**: 10 randomized clinical trials with a total of 934 randomized patients were included. Patients in the non-surgical group had a higher re-rupture rate than patients in the surgical group. However, re-rupture rates were equivalent (p = .08) if an early range of motion exercises protocol was performed. Lower incidence of complications (excluding re-rupture) was found in non-surgical patients.
**Conclusions**: Non-surgical treatment for acute Achilles tendon rupture is preferred if a functional rehabilitation protocol with early range of motion is possible. If not, surgical treatment should be considered because of the lower rate of re-rupture.

# Bunions (Hallux Valgus)

### Definition
- bony deformity characterized by medial displacement of first metatarsal and lateral deviation of hallux

### Mechanism
- many associated deformities in foot from altered mechanics
- valgus alignment of 1st MTP (hallux valgus), loose medial and tight lateral joint capsule, adductor hallucis becomes a deforming force
- formation of a reactive exostosis and thickening of the skin creates a bunion
- associated with poor-fitting footwear (high heel and narrow toe box)
- can be hereditary (70% have family history)
- 10x more frequent in women

### Clinical Features
- painful bursa over medial eminence of 1st MT head
- pronation (rotation inward) of great toe
- numbness over medial aspect of great toe

### Investigations
- X-ray: standing AP/lateral/sesamoid view, NWB oblique

### Treatment
- indications: painful corn or bunion, overriding 2nd toe
- non-operative (first-line)
  - properly fitted shoes (low heel) and toe spacer
- operative: goal is to restore normal anatomy, not cosmetic reasons alone
  - osteotomy with realignment of 1st MTP joint (Chevron Procedure)
  - arthrodesis

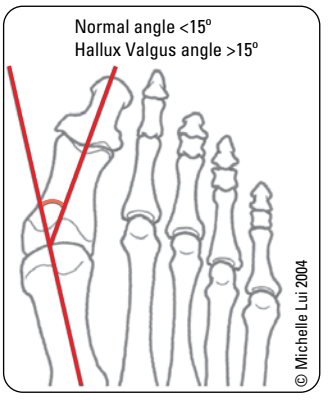

**Figure 49. Hallux valgus**

## Metatarsal Fracture

- as with the hand, 1st, 4th, 5th MT are relatively mobile, while the 2nd and 3rd are fixed
- use Ottawa Foot Rules to determine need for x-ray

**Table 23. Types of Metatarsal Fractures**

| Fracture Type | Mechanism | Clinical | Treatment |
|---|---|---|---|
| **Avulsion of Base of 5th MT** | Sudden inversion followed by contraction of peroneus brevis | Tender base of 5th MT | Conservative management |
| **Proximal Shaft of 5th MT (Jones Facture)** | Stress injury | Painful over base of 5th MT | *NWB BK cast x 6 wk<br>ORIF if athlete |
| **Shaft 2nd, 3rd MT (March Fracture)** | Stress injury | Painful shaft of 2nd or 3rd MT | Symptomatic |
| **1st MT** | Trauma | Painful 1st MT | ORIF if displaced otherwise<br>*NWB BK cast x 3 wk then walking cast x 2 wk |
| **Tarso-MT Fracture – Dislocation (Lisfranc Fracture)** | Fall onto plantar flexed foot or direct crush injury | Pain over base of 2nd MT<br>Swelling over midfoot<br>Inability to bear weight | ORIF |

*NWB BK = Non weight bearing, below knee

**Ottawa Ankle and Foot Rules**
(see Emergency Medicine, ER17)
X-rays only required if:
Pain in the midfoot zone AND bony tenderness over the navicular or base of the fifth metatarsal OR inability to weight bear both immediately after injury and in the ER

# Pediatric Orthopedics

## Fractures in Children

- type of fracture
  - thicker, more active periosteum results in pediatric-specific fractures: greenstick (one cortex), torus (i.e. 'buckle', impacted cortex) and plastic (bowing)
  - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
  - adults fracture through both cortices
- epiphyseal growth plate
  - weaker part of bone, susceptible to fractures
  - plate often mistaken for fracture on x-ray and vice versa (X-ray opposite limb for comparison), especially in elbow
  - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
  - intra-articular fractures have worse consequences in children because they usually involve the growth plate
- anatomic reduction
  - gold standard with adults
  - accept greater angular deformity in children (remodelling minimizes deformity)
- time to heal
  - shorter in children
- always be aware of the possibility of child abuse
  - make sure stated mechanism compatible with injury
  - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including X-ray evidence of healing fractures at different sites and different stages of healing
  - common suspicious fractures in children: metaphyseal corner fracture (hallmark of non-accidental trauma), femur fracture <1 year old, humeral shaft <3 year old, sternal fractures, posterior rib fractures, spinous process fractures

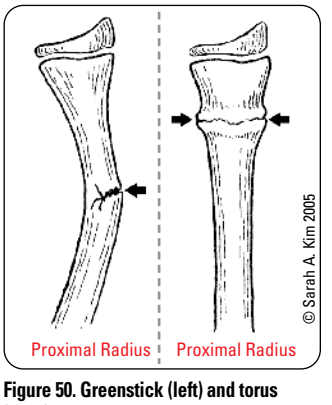

**Figure 50. Greenstick (left) and torus (right) fractures**

Greenstick fractures are easy to reduce but can redisplace while in cast due to intact periosteum

# Stress Fractures

### Mechanism
- insufficiency fracture
  - stress applied to a weak or structurally deficient bone
- fatigue fracture
  - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- common in tibia, calcaneus, and metatarsals

### Diagnosis
- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan positive in 12-15 d

### Treatment
- rest from strenuous activities to allow remodelling (can take several months)

# Physeal Injury

**Table 24. Salter-Harris Classification of Epiphyseal Injury**

| SALT(E)R–Harris Type | Description | Treatment |
|---|---|---|
| **I (Straight through; Stable)** | Transverse through growth plate | Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth |
| **II (Above)** | Through metaphysis and along growth plate | Closed reduction and cast if anatomic; otherwise ORIF |
| **III (Low)*** | Through epiphysis to plate and along growth plate | Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate |
| **IV (Through and through)*** | Through epiphysis and metaphysis | Closed reduction and cast if anatomic; otherwise ORIF |
| **V (Ram)*** | Crush injury of growth plate | High incidence of growth arrest; no specific treatment |

* Types III – IV are more likely to cause growth arrest and progressive deformity

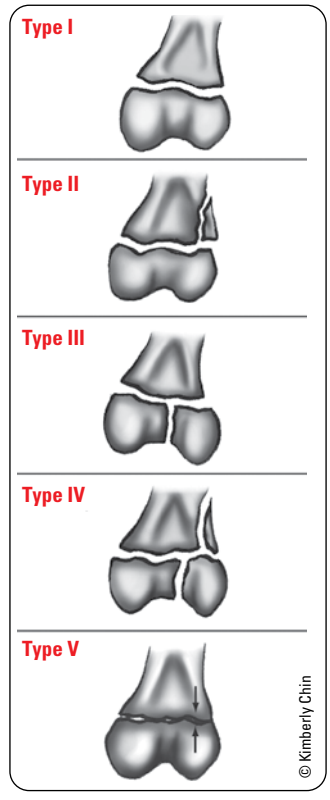

**Figure 51. Salter-Harris classification**

# Slipped Capital Femoral Epiphysis

- most common adolescent hip disorder, peak incidence at pubertal growth spurt

### Definition
- type I Salter-Harris epiphyseal injury at proximal hip

### Etiology
- multifactorial
  - genetic: autosomal dominant, black children at highest risk
  - cartilaginous physis hypertrophies too rapidly under growth hormone effects
  - sex hormone secretion, which stabilizes physis, has not yet begun
  - overweight: mechanical stress
  - trauma: causes acute slip
- risk factors: male, obese (#1 factor), hypothyroid (risk of bilateral involvement)

### Clinical Features
- acute: sudden, severe pain with limp
- chronic: typically groin and anterior thigh pain, may present with knee pain
  - positive Trendelenburg sign on affected side, due to weakened gluteal muscles
- tender over joint capsule
- restricted internal rotation, abduction, flexion
  - Whitman's sign: obligatory external rotation during passive flexion of hip
- Loder classification: stable vs. unstable (provides prognostic information)
  - unstable means patient cannot ambulate even with crutches

Bilateral involvement occurs in about 25%

### Investigations
- X-ray: AP, frog-leg, lateral radiographs both hips
  - posterior and medial slip of epiphysis
  - disruption of Klein's line
  - AP view may be normal or show widened/lucent growth plate compared with opposite side

**Klein's Line**
On AP view, line drawn along supero-lateral border of femoral neck should cross at least a portion of the femoral epiphysis. If it does not, suspect SCFE

### Treatment
- operative
  - mild/moderate slip: stabilize physis with pins in current position
  - severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion

### Complications
- AVN (roughly half of unstable SCFEs), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM

## Developmental Dysplasia of the Hip

### Definition
- abnormal development of hip, resulting in dysplasia and subluxation/dislocation of hip
- most common orthopedic disorder in newborns

### Etiology
- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions
  - dislocated femoral head completely out of acetabulum
  - dislocatable head in socket
  - head subluxates out of joint when provoked
  - dysplastic acetabulum, more shallow and more vertical than normal

### Physical Exam
- diagnosis is clinical
  - limited abduction of the flexed hip (<60°)
  - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  - Barlow's test checks if hips are dislocatable
    - flex hips and knees to 90° and grasp thigh
    - fully adduct hips, push posteriorly to try to dislocate hips
  - Ortolani's test checks if hips are dislocated
    - initial position as above but try to reduce hip with fingertips during abduction
    - positive test: palpable clunk is felt (not heard) if hip is reduced
  - Galeazzi's sign
    - knees at unequal heights when hips and knees flexed
    - dislocated hip on side of lower knee
    - difficult test if child <1 yr
    - Trendelenburg test and gait useful if older (>2 yr)

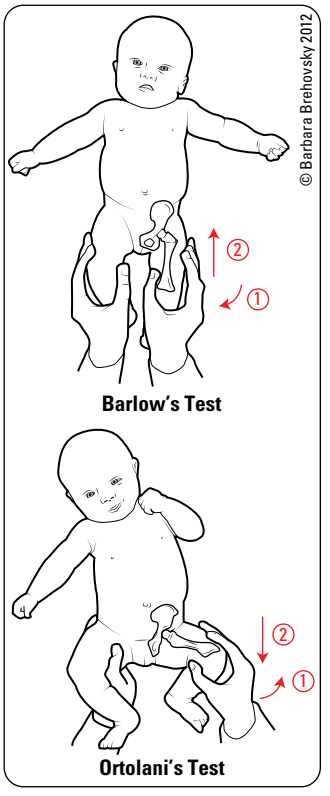

**Figure 52. Barlow's test and Ortolani's test**

### Investigations
- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow-up radiograph after 3 mo
- X-ray signs (at 4-6 mo): false acetabulum, acetabular index >25°, broken Shenton's line, femoral neck above Hilgenreiner's line, ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's lines) (Figure 56)

### Treatment
- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- >18 mo: open reduction; pelvic and/or femoral osteotomy

### Complications
- redislocation, inadequate reduction, stiffness
- AVN of femoral head

**5 Fs that Predispose to Developmental Dysplasia of the Hip**
**F**amily history
**F**emale
**F**rank breech
**F**irst born
Le**F**t hip

## Legg-Calvé-Perthes Disease (Coxa Plana)

### Definition
- idiopathic AVN of femoral head, presents at 4-8 yr of age
- 12% bilateral, M>F = 5:1, 1/1200
- associations
  - family history
  - low birth weight
  - abnormal pregnancy/delivery
  - ADHD in 33% of cases, delayed bone age in 89%
  - second-hand smoke exposure
  - Asian, Inuit, Central European
- key features
  - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Most common in adolescent athletes, especially jumping/sprinting sports

Children diagnosed with coxa plana <6 yr of age have improved prognosis

### Clinical Features
- child with antalgic or Trendelenburg gait ± pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip): decreased internal rotation and abduction of hip
- limb length discrepancy (late)

### Investigations
- X-ray: AP pelvis, frog leg laterals
- initially, may be negative; if high index of suspicion, move to bone scan or MRI
- eventually, collapse of femoral head will be seen (diagnostic)

### Treatment
- goal is to preserve ROM and keep femoral head contained in acetabulum
- non-operative
  - physiotherapy: ROM exercises
  - brace in flexion and abduction x 2-3 yr (controversial)
- operative
  - femoral or pelvic osteotomy (>8 yr of age or severe)
    - prognosis better in males, <6 yr, <50% of femoral head involved, abduction >30°
- 60% of involved hips do not require operative intervention
- natural history is early onset OA and decreased ROM

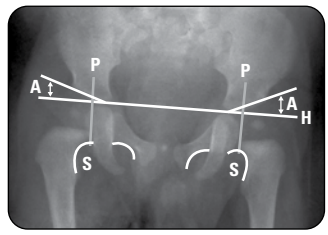

**Figure 53. Pelvic x-ray and reference lines and angles for assessment of DDH**
**Triradiate Cartilage**
y-shaped epiphyseal plate at junction of ilium, ischium and pubis
**Hilgenreiner's Line**
Line running between triradiate cartilages
**Perkin's Line**
Line through lateral margin of acetabulum, perpendicular to Hilgenreiner's Line
**Shenton's Line**
Arced line along inferior border of femoral neck and superior margin of obturator foramen
**Acetabular Index**
Angle between Hilgenreiner's Line and line from triradiate cartilage to point on lateral margin of acetabulum

## Osgood-Schlatter Disease

### Definition
- inflammation of patellar ligament at insertion point on tibial tuberosity
- M>F; boys 12-15 yr; girls 8-12 yr

### Mechanism
- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

### Clinical Features
- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

### Investigations
- X-ray lateral knee: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

### Treatment
- benign, self-limited condition, does not resolve until growth halts
- non-operative (majority)
  - may restrict activities such as basketball or cycling
  - NSAIDs, rest, flexibility, isometric strengthening exercises
  - casting if symptoms do not resolve with conservative management
- operative: ossicle excision in refractory cases (patient is skeletally mature with persistent symptoms)

## Congenital Talipes Equinovarus (Club Foot)

### Definition
- congenital foot deformity
- muscle contractures resulting in CAVE deformity
- bony deformity: talar neck medial and plantar deviated; varus calcaneus and rotated medially around talus; navicular and cuboid medially displaced

### Etiology
- intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction); may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity
- 1-2/1000 newborns, 50% bilateral, occurrence M>F, severity F>M

### Physical Exam
- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)
- diagnosis is often from physical exam findings alone, radiographs not always required

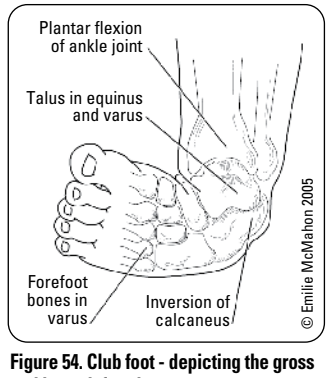

**Figure 54. Club foot - depicting the gross and bony deformity**

**CAVE deformity**
- Midfoot **C**avus
- Forefoot **A**dductus
- Hindfoot **V**arus
- Hindfoot **E**quinus

### Treatment
- largely non-operative via Ponseti Technique (serial manipulation and casting)
  - correct deformities in CAVE order
    - change strapping/cast q1-2wk
    - surgical release in refractory case (rare)
      - delayed until 3-4 mo of age
- 3 yr recurrence rate = 5-10%
- mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf muscle atrophy

# Scoliosis

### Definition
- lateral curvature of spine with vertebral rotation
- age: 10-14 yr
- more frequent and more severe in females

### Etiology
- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

### Clinical Features
- cosmetic concern ± back pain
- primary curve where several vertebrae affected
- secondary compensatory curves above and below fixed primary curve to try and maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam's test: rib hump when bent forward
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scoliosis
  - café-au-lait spots, dimples, neurofibromas
  - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

### Investigations
- X-ray: 3-foot standing, AP, lateral
  - measure curvature: Cobb angle
  - may have associated kyphosis

### Treatment
- based on Cobb angle
  - <25°: observe for changes with serial radiographs
  - >25° or progressive: bracing (many types) that halt/slow curve progression but do not reverse deformity
  - >45°, cosmetically unacceptable, or respiratory problems: surgical correction (spinal fusion)

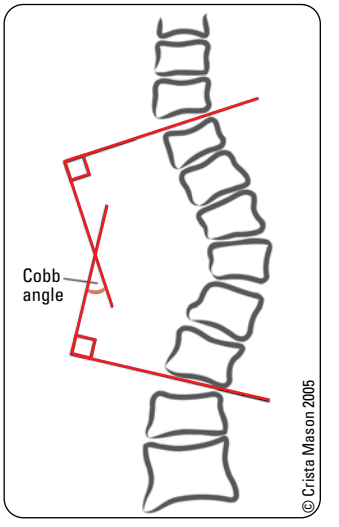

**Figure 55. Cobb angle** – used to monitor the progression of the scoliotic curve

Scoliosis screening is not recommended in Canada (Grieg A, et al. 2010; Health Canada, 1994)

In structural or fixed scoliosis, bending forwards makes the curve more obvious

Postural scoliosis can be corrected by correcting the underlying problem

# Bone Tumours

- primary bone tumours are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

### Clinical Features
- malignant (primary or metastasis): local pain and swelling (weeks to months), worse on exertion and at night, ± soft tissue mass
- benign: usually asymptomatic
- minor trauma often initiating event that calls attention to lesion

**Red Flags**
- Persistent skeletal pain
- Localized tenderness
- Spontaneous fracture
- Enlarging mass/soft tissue swelling

**X-ray Findings**
- Lytic, lucent, sclerotic bone
- Involvement of cortex, medulla, soft tissue
- Radiolucent, radiopaque, or calcified matrix
- Periosteal reaction
- Permeative margins
- Pathological fracture
- Soft tissue swelling

**Table 25. Distinguishing Benign from Malignant Bone Lesions on X-Ray**

| Benign | Malignant |
|---|---|
| No periosteal reaction | Acute periosteal reaction<br>• Codman's triangle<br>• "Onion skin"<br>• "Sunburst" |
| Thick endosteal reaction<br>Well developed bone formation<br>Intraosseous and even calcification | Broad border between lesion and normal bone<br>Varied bone formation<br>Extraosseous and irregular calcification |

Adapted from: Buckholtz RW, Heckman JD. Rockwood and Green's Fractures in Adults. Volume 1. Philadephia: Lippincott Williams & Wilkins, 2001. p558

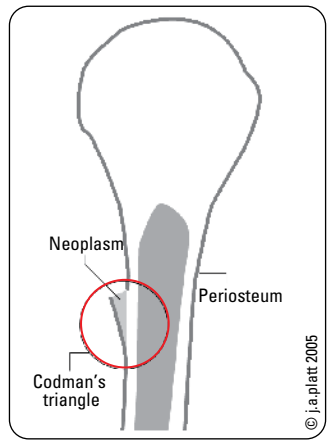

**Figure 56. Codman's triangle** – a radiographic finding in malignancy, where the partially ossified periosteum is lifted off the cortex by neoplastic tissue

### Diagnosis
- malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
- staging should include:
  - blood work including liver enzymes
  - CT chest
  - bone scan
  - bone biopsy
    - should be referred to specialized centre prior to biopsy
    - classified into benign, benign aggressive, and malignant
  - MRI of affected bone

# Benign Active Bone Tumours

## BONE-FORMING TUMOURS

### Osteoid Osteoma
- bone tumour arising from osteoblasts
- peak incidence in 2nd and 3rd decades, M:F = 2:1
- proximal femur and tibia diaphysis most common locations
- not known to metastasize
- radiographic findings: small, round radiolucent nidus (<1.5 cm) surrounded by dense sclerotic bone ("bull's-eye")
- symptoms: produces severe intermittent pain from prostaglandin secretion and COX1/2 expression, mostly at night (diurnal prostaglandin production), thus is characteristically relieved by NSAIDs
- treatment: NSAIDs for night pain; surgical resection of nidus

## FIBROUS LESIONS

### Fibrous Cortical Defect
- i.e. non-ossifying fibroma, fibrous bone lesion
- most common benign bone tumour in children, typically asymptomatic and an incidental finding
- occur in as many as 35% of children, peak incidence between 2-25 yr old, higher prevalence in males
- femur and proximal tibia most common locations, 50% of patients have multiple defects that are usually bilateral, symmetrical
- radiographic findings: diagnostic, metaphyseal eccentric 'bubbly' lytic lesion near physis; thin, smooth/lobulated, well-defined sclerotic margin
- treatment: most lesions resolve spontaneously

### Osteochondroma
- cartilage capped bony tumour
- 2nd and 3rd decades, M:F = 1.8:1
- most common of all benign bone tumours – 45%
- 2 types: sessile (broad based and increased risk of malignant degeneration) vs. pedunculated (narrow stalk)
- metaphysis of long bone near tendon attachment sites (usually distal femur, proximal tibia, or proximal humerus)
- radiographic findings: cartilage-capped bony spur on surface of bone ("mushroom" on x-ray)
- may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
- generally very slow growing and asymptomatic unless impinging on neurovascular structure ('painless mass')
  - growth usually ceases when skeletal maturity is reached
- malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)
- treatment: typically observation; surgical excision if symptomatic

### Enchondroma
- hyaline cartilage tumour; majority asymptomatic, presenting as incidental finding or pathological fracture
- 2nd and 3rd decades
- 60% occur in the small tubular bones of the hand and foot; others in femur (20% - Figure 57), humerus, ribs
- benign cartilaginous growth, an abnormality of chondroblasts, develops in medullary cavity
  - single/multiple enlarged rarefied areas in tubular bones
  - lytic lesion with sharp margination and irregular central calcification (stippled/punctate/popcorn appearance)
- malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
- not known to metastasize
- treatment: observation with serial x-rays; surgical curettage if symptomatic or lesion grows

**Figure 57. T1 MRI of femoral enchondroma**

### CYSTIC LESIONS

### Unicameral/Solitary Bone Cyst
- most common cystic lesion; serous fluid-filled lesion
- children and young adults, peak incidence during first 2 decades, M:F = 2:1
